Mr. J. D. MALCOLM read a paper on this subject. He argued that the nervous system of the intestine was temporarily put out of gear by the stimulations associated with exposure and manipulation of the peritoneum during abdominal operations, results being a delayed activity of the propelling function of the alimentary canal and as a consequence some degree of discomfort, nausea, and distension of the abdomen, the action of a purgative being frequently necessary to restart normal peristaltic activity. Occasionally it was impossible to get the bowels to move by any means, and then if there was no other complication a tympanites developed and continued until death took place. In some such cases life could be saved by making an intestinal fistula. This treatment if it effected a cure was followed by a subsidence of the distension and by a movement of the bowels a few days later in response to enemata or to purgatives. The fistula was closed after a time without any subsequent bowel difficulty. Under such circumstances there was clearly no paralysis and no obstruction of any part of the intestine, only a short rest of the lower bowel was necessary to effect a cure. When such cases died unrelieved signs of septic peritonitis were always found at an autopsy if the patient died slowly, because micro-organisms passed from the bowel to the peritoneum when the patient was *in extremis*. But in many such cases there was no spreading peritonitis when a second operation was performed, and therefore the peritonitis followed and could not be the cause of the tympanites. Intestinal adhesions might aggravate the difficulties of the propelling force even if a complete mechanical obstruction was not produced. Opiates also induced symptoms of obstruction. The chief object of the paper, the speaker said, was to differentiate those cases in which trouble began with an inefficient peristalsis from others in which a septic-spreading peritonitis was the first pathogenic condition and was followed by paralysis of the bowel and tympanites. Unless these two classes of cases were recognised many of the conditions following operations upon the abdomen could not be understood, and confusion must arise between the peritonitis which was a cause of tympanites and the peritonitis which was a consequence of tympanites.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Hæmatemesis and Melæna Neonatorum.—Vaginal Plug.

A MEETING of this section was held on April 20th, Dr. GIBBON FITZGIBBON, the President, being in the chair.

Dr. BETHEL SOLOMONS read some notes on a case of Hæmatemesis and Melæna Neonatorum. The bleeding started on the day after the delivery, which was uneventful, and large amounts of red blood were passed by the mouth and rectum. The detailed history of the case was given, and the following points were noted:—

1. That the child was a female; the condition being supposedly more common in males. 2. The fact that ice-cold water, which is recommended in these cases, causes great pain; while, when the chill is removed, hæmorrhage does not recommence, and there is no more pain. 3. That starvation can be sustained for so many days (six in this case). 4. That the cure in this case was effected by good nursing, warmth, quiet, water, a mixture of adrenalin chloride and calcium lactate, and the injection of horse serum; that the baby disimproved when the serum was temporarily stopped, and improved when administered again; that large doses of serum give better results than small, and that when given hypodermically or by the mouth the result seems to be the same; that while no anaphylaxis was noticeable in this case, the physician should always be ready for this phenomenon, for which the best treatment is pituitary extract in small doses. 5. That it was possible that the ulceration in the gastro-intestinal tract was caused by some toxin carried from the mother to the child while still in utero.

Dr. E. HASTINGS TWEEDY said that these cases were nearly always due to duodenal ulcer, and horse serum in massive doses appeared to act as a specific. The dose should not be smaller than 10 c.c. It was seldom necessary to repeat the dose. Once the bleeding ceased the infant's condition rapidly improved, and perforation of the bowel appeared never to occur. Starvation was unnecessary for more than two days; breast-milk might then be given.—Dr. SPENCER SHEILL said that he had published notes of a similar case two years ago, the treatment of which by horse serum was the first recorded success. He believed a more rapid and successful result would have been obtained by 10 c.c. doses of serum, instead of the smaller and repeated doses.—Dr. W. M. CROFTON thought the serum must act by inducing a larger production of thrombin, since, if mixed with fresh blood outside the body, it delayed clotting. He described two cases of anaphylaxis occurring after the first injection of serum intravenously, and discussed the probable cause of the change in the serum producing this. These cases had led him to introduce pituitrin for the treatment of anaphylaxis. He criticised the exhibition of lime salts by the mouth, suggesting that they could have been better given in the form of the mother's milk.

Dr. HASTINGS TWEEDY read a paper on the Ability of the Vaginal Plug to Cause a Direct Pressure on the Uterine Vessels and on the Side Walls of the Pregnant Uterus. He said that the plug had a different significance in Dublin from that which it enjoyed elsewhere. It was impossible to cause compression of the uterine vessels if rolls of cotton-wool (each tied round with a string) were passed into the vagina with the aid of a speculum and plugging forceps. If, on the contrary, the left hand was entirely inserted into the vagina and small pledgets of moist cotton-wool were inserted by means of the other hand, it was comparatively easy to press from 30 to 40 separate pieces into the canal and to force up the lateral fornices until a hard tumour could be felt rising high above Poupart's ligament. In the year 1898 he had brought forward evidence that a plug so inserted was able to stop the circulation of the uterine vessels. Recently, in a series of Cæsarean sections, he had been able to demonstrate in a convincing manner that the plug acted in the way explained in his former paper.

MEDICAL STUDENTS IN SWITZERLAND.—The total number of students studying medicine at the Swiss universities during the winter 1916-17 was 1801, of whom 291 were women. Out of this number 726 were foreigners, and of these 185 were women. The students were distributed as follows: Basle, 215; Berne, 411; Geneva, 512; Lausanne, 248; Zurich, 515.

THE LANCET.

LONDON: SATURDAY, MAY 12, 1917.

Science and the Nation.

"WHAT people call Applied Science is nothing but the application of Pure Science to particular classes of problems," said Professor HUXLEY, and thus corrected a popular misunderstanding of the times which still flourishes, if not so freely now as then. For certainly the mass of the public believe that the man engaged in research—the chemist or physicist in the highly organised laboratory attacking specialised problems—is not bringing the mystical qualifications, with which they willingly credit him, to bear upon the practical issues of life. This frame of mind arises from two main causes. The first is the ignorance of the public of the grammar of science, an ignorance displayed even by the men whose daily routine brings them into immediate contact with the results of scientific research. It does not enter into the mental equipment of the average citizen to understand, even in a general way, the terms of science or the obvious phenomena of chemistry or physics. In the factory, the brewery, the railway shed, he knows accurately many things, but his knowledge is utilised for the most part empirically and specially—he has little idea of the general significance of what he is engaged upon. He has never had education along the necessary lines. The second main cause is no less obvious why the public do not perceive that the applied knowledge, which activates the best part of the world's activity, is just the knowledge which at first emanated from research. It is this. The worker in "pure" science does not and cannot announce beforehand that he is going to solve a certain problem, or to make a discovery which will have a certain outcome in "applied" science; hence, when the public come into possession of the results of research, no history reaches them connecting the practical benefits, which the public *can* appreciate, with anything which anyone has previously done in a laboratory. In this way the debt owed to research goes unrecognised, and the oversight may have a specially dangerous sequel to-day. For all can see that after the world-war many industries will have to be rebuilt which rely wholly upon applied science; and there will be an enormous impetus given to the output of all sorts of commodities, the manufacture of which depends upon the use of high technical knowledge. Attempts to go forward on the commercial side without reference to the proper source of energy—namely, research—will be slow, ill-directed, and unsuccessful.

Recognition of this position has inspired a group of Cambridge graduates, holding high positions in their branches of pure science, to write a series of essays demonstrating how research carried on in their various departments has led in the past, and is leading now, to the conduct of the business of life in its most useful, nay, most indispensable, forms. No one needs to be convinced on this point as far as mathematics and physics are concerned, but in other directions the evidence does not lie so clearly in sight, and its production in these essays may be very valuable. Mr. WALTER ROSENHAIN, superintendent of the Metallurgy Department of the National Physical Laboratory, for instance, proves that our immense strides in metallurgy, enabling metal strains to be definitely calculated and "fatigue" avoided, and alloy steels and aluminiums to be manufactured of infinite hardness, started with the invention, in the course of research work by LE CHATELIER, of the thermo-couple for the registration of enormous temperatures, and with the discovery by HENRY CLIFTON SORBY of the crystalline structure of metals; and it is piquant here to recall that the importance of SORBY'S work was quite unrecognised at the time when it was done, while he himself could not have been aware of its great significance. Mr. F. W. KEEBLE, director of the Royal Horticultural Society's Gardens at Wisley, Mr. W. DAWSON, reader in forestry at Cambridge, Mr. R. H. BIFFEN, professor of agricultural botany, and Mr. T. B. WOOD, Draper's professor of agriculture in the same University, show respectively how the methods of intensive cultivation have been discovered by research; how the output of timber, for some time so perilously short in this country, can be largely increased by attention to scientific procedures, planned and tested in the laboratory; how systematised breeding may improve the yielding capacity of wheat, and place the nutrition of farm animals upon a rational basis. More than one of these writers point to the botanical experiments of GREGOR MENDEL in the garden of an abbey as the inspiration of scientific labours that are already bearing famous fruit; for MENDEL, like SORBY, was building better than he knew, and illustrating the impossibility of prophesying what will be the scope or influence of any scientific discovery at the moment that it is made. The examples of the association between research and manufacture given by Professor W. J. POPE, professor of chemistry at Cambridge, in the opening essay of the series, are drawn from the conditions of war, and he points, as we have done already in these columns, to the curious fact that certain great chemical industries, like dyeing and the preparation of synthetic drugs, sources of enormous wealth in times of peace, can be transformed in times of war into manufactories for high explosives. The moral to be drawn here lies on the surface for this country. If we had been able as a nation to receive with intelligence the information from the laboratories of our scientific chemists, we should not have allowed these great industries to be wrested from us by the Germans, who grew fat on them in times of peace, and have employed them against us, to our unspeakable hurt, throughout the war. The nation was deaf to the message of its chemists.

Lord MOULTON, one of our most learned citizens, in an introduction to the essays which highly

commends their study (as we are now doing), believes that the vague and artificial distinction between pure and applied science does not exist as an influential principle in this country. This is excellent hearing for the votaries of medicine, who can show good cause why there should be full appreciation of medical progress. Indeed, medical research, since discovery extended the scope of medicine from that of an art to that of a science, has bestowed through its practical application benefits upon mankind that can no longer escape popular recognition. The essays dealing with the subject are written by Professor GOWLAND HOPKINS, Professor G. H. F. NUTTALL, and Dr. G. S. GRAHAM SMITH, respectively occupying chairs in biochemistry, biology, and hygiene at Cambridge, and they form an admirable exposition of the way in which the highest forms of academic work have rapidly found public applications resulting in the saving already of untold lives. We need not traverse with medical readers the well-known country where the landmarks are the discoveries of PASTEUR, LISTER, KOCH, LAVERAN, MANSON, ROSS, METCHNIKOFF, BEHRING, EHRLICH, GORGAS, WRIGHT, BRUCE, and others, or narrate the wonderful ingenuity and bravery by which the Panama Canal zone was freed from yellow fever; but we congratulate the authors of the papers dealing with medical research upon drawing a map of that country which for all who are commonly intelligent furnishes lucid information upon technical matters of extreme complexity. The last essay, by Captain W. H. R. RIVERS, on the value of anthropological knowledge to an empire which has the charge of many subject races, differs from the other contributions in omitting marked examples of success following the application of scientific teachings; but the writer has no difficulty in convincing us that official blindness to the lessons of ethnology has not seldom had tragic consequences for ourselves and our dependents.

We desire for this excellent little volume[1] the widest possible circulation; it is a winning brief for those who have been advocating for years the endowment of pure research in this country. A start has been made, as far as medicine is concerned, with the Medical Research Bureau, but the satisfactory beginning must have far larger developments.

The Rationing of the People.

THE Royal proclamation issued last week as to the necessity of husbanding our food supplies no doubt brought home to a good many still sceptical and heedless people the seriousness of the situation, and now we have Lord DEVONPORT'S statement in the House of Lords last Tuesday that preliminary steps are being taken to put into force a scheme of rationing the nation. It will necessarily be a vast piece of administrative machinery which will require the utmost care and consideration in regard to detail and its subsequent application to the common affairs of our daily life. We must profit all we can by the experience of the past, and especially from the mistakes of those nations which have attempted a practical and systematic solution of the problem. There are already many lessons before us which should not require to be learned again. In any case we shall be called upon to exercise patience and forbearance, and in this we may be helped by the hope that it will not be long before the situation is relieved in obvious ways. Our physiological authorities have done well to urge not only what are the daily requirements of the individual in regard to the kind and amount of food necessary for maintenance, but also to point out the great importance of basing allowances upon the demands placed upon the energies of that individual. Dr. M. S. PEMBREY, in a paper published in our present issue, refers to this aspect of the question and rightly says that a system of rations which pays no attention to occupation is absurd, for clearly the man who does essential muscular work must have a greater amount of food than the sedentary worker. Otherwise our national efficiency may well be impaired. The particular food needs of the children in the family will call also for special attention; and, indeed, the whole system of rationing, while in any case it must mean exercising considerable economies, must have a logical or physiological basis or the results may be disastrous. The handing out of rations, in other words, must be scientifically fair so far as the situation permits. Lord DEVONPORT said that it was his endeavour to take no measures which would benefit the rich at the expense of the poor. Such preference will be immensely hard to avoid, and can only be avoided by limiting each consumer to the number of calories required to maintain his body heat and perform the work required of him. Any consumption of food in excess of this limit, irrespective of purchasing power, must be made impossible for rich and poor alike, if Lord DEVONPORT'S action is to have effect. This can be secured by getting a return of the routine of the daily life and domestic situation of the individual. All these questions, we are sure, are being carefully considered by the Food Controller, who has, no doubt, received the counsels of the strong advisory body of scientific men placed at his disposal. They are not likely to miss any single point vital to the issue, but if this should happen the error will be immediately detected, when readiness to modify any instructions will be displayed by those in authority, who have always shown themselves ready to take advantage of popular experience.

[1] Science and the Nation: Essays by Cambridge Graduates. With an Introduction by the Right Hon. Lord Moulton, K.C.B., F.R.S. Edited by A. C. Seward, Master of Downing College, Cambridge. Cambridge University Press. 1917. Pp. 328. 5s. net.

DONATIONS AND BEQUESTS.—The late Mr. Joseph Taylor, of The Bungalow, Great Barr, Staffordshire, has left by will £20,000 to the Walsall and District Hospital, £10,000 to the Walsall Victoria Nursing Institution, £5000 to Queen's Hospital, Birmingham, and £2000 each to the Birmingham and Midland Eye Hospital, the Society for the Prevention of Cruelty to Animals, the Wolverhampton and Midland Counties Eye Infirmary, and the Midland Counties Home for Incurables, Leamington.—By will the late Mr. James Forrest, of St. Leonards-on-Sea, has left £5000 in trust, which will ultimately be divided between St. George's, the Middlesex, and the Westminster hospitals and the Victoria Hospital for Children.—The late Mrs. Anne Chambers, of Prince's-gate, W., has left £1000 to the Staffordshire General Infirmary.

Annotations.

"Ne quid nimis."

LESSONS OF THE WAR IN THE MATTER OF WATER-SUPPLY.

RIVERS as sources of water-supply—at least in the cases of the Thames and Lee—were very nearly ruled out some years ago when it was seriously proposed to draw on the watersheds of Wales for the supply of water to the metropolis, following the schemes adopted by Liverpool and Birmingham. Manchester draws its supply from Thirlmere Lake in Cumberland and Glasgow from Loch Katrine. An important difference between lake and mountain supplies and the generality of river supplies is that the former are invariably free from lime salts, while the latter are hard. This last quality is a source of considerable trouble and expense to water consumers in London, and notably to those in the Kent districts where no attempt is made to soften the water derived directly from the chalk wells. Of course, it is of prime importance that attention should be given to organic rather than to inorganic quality, and this is what has been admirably done in the case of the river-drawn supplies to the metropolis. We may, perhaps, hope that now it appears to be well established that raw river-water can be purified to any required standard of safety the future may see a softened supply also. It is doubtful whether a hard water-supply has any prejudicial effect upon the public health, but in many directions the advantages of a soft water-supply are obvious and would result in considerable domestic and technological economies. Dr. A. C. Houston, the director of water examinations, Metropolitan Water Board, whose arduous labours on the subject have brought the metropolitan water-supply to its present constancy and purity, has shown[1] that there are several reasons leading to the belief that rivers are likely to be used to an increasing extent as sources of water-supply. First of all, our sources of supply are limited, and many of the available watersheds are already appropriated. Then the danger of using river water for potable purposes has in the past been exaggerated; although it should be remembered that Dr. Houston is speaking in the light of present important methods of purification largely the outcome of his own investigations. Finally, he says, there are cases where there is an economic gain in the choice or in the retention of a river water-supply, adding "for many years to come, any *legitimate* means of saving money ought to be regarded as a national duty." It was the need for economy which led also to the use of a chlorination method of sterilisation which saved a considerable amount of money and time expended in storage in the great reservoirs. Whether such a course would have been adopted by this time had not these great national economical considerations arisen is a matter of opinion. The end, however, has justified the means. Dr. Houston frankly says he is not pledged to support sterilisation or any other special method of water purification. At the same time he feels that the war has taught us many lessons, including the necessity of subordinating sentiment to expediency. Pure water is a prime necessity of life, and, ideally, to obtain it we should draw on a pure source of supply. But we have to deal with the situation as we find it, and we are faced with an impure supply. The only recourse then is to put into execution methods which without doubt render the raw material wholesome. This Dr. Houston has done, and he is confident of continuing able to do so. It is a responsibility that has been finely undertaken.

THE IMMEDIATE MOVEMENT OF INJURED JOINTS.

AT a meeting of the Académie de Médecine of Paris M. Ch. Willelms, director of the Belgian Military Hospital of Hoogstaede, described his treatment of wounds of joints by immediate mobilisation. In 1909 he first advocated the treatment of hæmarthrosis of the knee by puncture followed by immediate walking. Though opposed to current teaching this treatment obtained supporters at once. Those who had the courage to try it found it superior to other methods by reason of its simplicity, complete innocuity, and rapidity of cure. Extending this treatment, M. Willelms applied it to grave injuries of joints other than hæmarthrosis. From industrial accidents he extended the treatment to military surgery. He is now convinced that the current method of treatment by immobilisation is defective and should be abandoned. It leads to stiffness of joints and atrophy of muscles which never occur under the new method. The former can be avoided by passive movements, but muscular wasting can be completely prevented only by active movements. To prevent atrophy of the quadriceps it is not sufficient that the patient performs movements of flexion and extension of the knee while lying in bed. He must walk. Numerous objections may be made. It may be asked, Is not mobilisation painful? The performance of the function of a wounded joint is not painful, even when there are osseous lesions, provided no displacement is produced. Will not an articular wound render a joint incapable of performing its function? Incapacity occurs only at the beginning when the joint is distended by effusion, and later when muscular atrophy has developed. Will not the lesions be aggravated by the movements? On the contrary, the cicatrisation of articular and periarticular lesions is accelerated by active movements. So far from causing irritation, they favour absorption of effusion and infiltration, thanks to a kind of internal massage so produced. Can the movements aggravate infection? If the joint is closed or insufficiently opened movements may contribute to the diffusion of germs and the extension of arthritis. But if there is a good opening each movement has the effect of expelling pus, and the joint is better emptied than by drainage. Further, movements are the best method of promoting absorption of the periarticular exudation which always accompanies arthritis. In cases of wound of the knee produced by a rifle bullet without fracture there is often only a simple perforation. All that M. Willelms finds necessary is to cleanse and dress the wound. He then allows the patient to walk immediately. But for wounds due to shrapnel, shell, bomb, or grenade he performs free arthrotomy, excises the track, removes the projectile, and sutures the wound. A simple dressing is applied, and the patient is directed to perform movements as frequently and as extensively as possible, even to the

point of fatigue. He begins to walk after a few days, sometimes almost immediately. The same treatment is followed when the articular wound is accompanied by osseous lesions without tendency to displacement. If the damage of the bone is important immediate walking is out of the question, and movements of flexion and extension are ordered, their extent depending on the amount of sound cartilage left. If the greater part of an articular cartilage is destroyed there is no longer anything to call a joint, and mobilisation is without object. If there are extensive bony lesions the possibility of immediate mobilisation depends on the absence of any tendency to displacement of the fragments. If this is to be feared mobilisation must be abandoned. If the arthrotomy has not ensured complete disinfection of the joint arthritis will appear—not in consequence of the movements, but in spite of them. The joint must then be reopened more extensively than before, and while allowed to remain open the movements must be continued. The pus or other fluid will be expelled on each movement and ideal drainage realised.

ALOPECIA AREATA AND PARATHYROID DEFICIENCY.

Alopecia areata, or area celsi as it is often called, is a not uncommon form of baldness. It is rapidly produced and patchy in its distribution; the patches often spread and may coalesce to such an extent as to render the patient completely hairless, though such extreme instances are rare. The common form of alopecia areata is that in which patches or bands of baldness occur on the scalp, characterised by the presence at the edges of hair-stumps shaped like marks of exclamation. The pathogenesis of the disease is obscure. In a few cases the distribution of the bald patch over the area of a cutaneous nerve, and its association with a local neuralgia, has suggested a local neuritis. To explain the ordinary cases three main hypotheses have been invoked. According to one view, the disease is microbic in origin, contagion occurring, although rarely, but no causative microbe has yet been found. According to a second view, it is trophoneurotic in origin, but against this hypothesis it may be urged that the disease is common in childhood and that the bald patches but rarely correspond with the distribution of any nerve. According to a third hypothesis alopecia areata is toxic in origin, the toxin, which is unknown, being either produced locally or carried to the affected area by the blood-stream. A fourth hypothesis of the pathogenesis of the disease has recently been advanced by Dr. G. C. Bolten.[1] He holds that it is a manifestation of latent tetany, and that it is due to deficiency of the secretion of the parathyroid glands. He bases this endocrine hypothesis, as it may be called, on two cases of the disease he has recently treated. One patient was a boy aged 9, the other a greengrocer of 48; both presented a single recognised sign of latent tetany—namely, the presence of Erb's sign—and the older patient in addition had brittle finger-nails and thick skin on the fingers, signs held by Dr. Bolten to be suggestive of latent tetany. Erb's sign consists in an increase of the excitability of the motor nerves to galvanic currents; the other well-known signs of tetany, known by the names of Trousseau and Chvostek, were not present in Dr. Bolten's patients and the Wassermann reaction was absent in both. The elder patient was neurotic, but otherwise in good health, and the boy appeared to be perfectly normal apart from his alopecia. Dr. Bolten does not specify the treatment he gave these two patients and, more particularly, makes no mention of medication with parathyroid gland substance or extract.

[1] Nederl. Tijdschr. v. Geneeskunde, Amsterdam, 1917, i., 24.

THE SANITATION OF PUBLIC BUILDINGS IN THE UNITED STATES.

THE benefits that accrue to the United States from having an organised body of medical health officers united into a Public Health Service manifest themselves in divers ways. For the service has its own inspectors, bacteriologists, laboratories, and chemists, and appears to be hampered by no limitations of scope. It was this service which organised the campaign against ground squirrels in California when there was fear of plague, and which extinguished the now forgotten charlatan Friedmann, who tried to exploit a turtle-grown tuberculin. The latest field of action reported is the sanitary inspection of public buildings in Washington, D.C., the results of which are set out by Dr. J. R. Hurley, of the United States Public Health Service, in a recent issue of the *Military Surgeon*. We learn that in 1912 the officers of the Public Health Service were ordered regularly to inspect all Government buildings in Washington except those of the Navy and Army. Some of these are museums and historic buildings visited by large numbers of people, some are mere offices; they are very various and their management differs accordingly. From the accounts given it is obvious that practices vary, but principles emerge, and to these we direct attention. Thus the best ventilation is held to be by the double supply and exhaust system. Usually the office windows are opened for five minutes in the middle of the morning and afternoon, the staff during these periods "stirring around." Desk fans are advocated and steam heating, the resulting dryness of the air preventing inconvenience from the high temperature reached, which is no less than 78° F. To us it appears no wonder that ice-water is freely supplied. The optimum is considered to be reached at lower temperatures with 76 per cent. relative humidity. Indirect electric lighting is preferred because of freedom from glare and distinct shadows. A cream-coloured ceiling and light shades of buff or green flat-surfaced paint that can be washed are recommended for walls. The Public Health Service makes itself responsible in a detailed way for the lavatory and similar accommodation of employees, and in the Government Buildings at Washington these things appear from the report to be carefully watched. Every Government employee is provided with a clean individual towel once a week, while hot water, liquid soap, and paper towels are in use in the lavatories. Rest rooms for women are fitted up in practically all the buildings where women are employed, sometimes with a matron in charge, and sanitary towels are supplied by automatic machines or otherwise. Stress is laid by the Public Health Service on orderliness of offices. The disorderly office, says the report, cannot be cleaned—papers on the floor cannot be disturbed by the cleaners for fear of loss. Books and papers for record are therefore to be sent to filing rooms promptly, and all coats and hats to dressing-rooms. All unnecessary

pictures are prohibited and the office furniture must be made to stand on feet to permit cleaning underneath. This careful inspection of Government offices at Washington raises the standard of welfare of Government employees, and should improve the whole standard of working office conditions throughout the United States. Official life in England is now very crowded, and we recommend the idea of the general inspection of public offices to the Local Government Board.

A DISCUSSION ON TOXIC JAUNDICE.

A FULL report of the discussion on toxic jaundice in munition workers arising from trinitro-toluene and tetrachlorethane, which took place at the Royal Society of Medicine on Jan. 23rd last, has been issued as a separate volume of the Proceedings at 7*s.* 6*d.* Dr. T. M. Legge, H.M. Medical Inspector of Factories, indicates in his introductory remarks the extent of the problem which industrial toxic jaundice now presents, and its study will be found to throw a flood of light on much that has hitherto been obscure in disease of the liver and blood. The etiology, symptoms, pathology, and preventive measures are dealt with by those who have had the widest experience of this new industrial disease. Dr. H. M. Turnbull, pathologist to the London Hospital, states it as his opinion that the study of the lesions caused by trinitro-toluene in the liver should be of great assistance in the elucidation of the causes of examples of similar atrophy of unknown etiology found from time to time in the post-mortem room, and a similar study of the effect upon the blood and the blood-forming organs should go far to clear up the cause of various forms of so-called idiopathic anæmia. The liver changes are beautifully illustrated by three coloured plates and several microphotographs of specimens prepared by Captain Matthew J. Stewart, R.A.M.C., pathologist to the Royal Infirmary, Leeds. Both he and Dr. P. N. Panton lay stress upon the polymorphonuclear leucopenia, often of extreme degree, found in several cases. Dr. Benjamin Moore, F.R.S., emphasises the probability of absorption directly through the skin playing a leading part in causation, and the importance of clean working as a corollary. A useful summary of the discussion by Surgeon-General H. D. Rolleston concludes the issue.

HEART FAILURE DURING AN OPERATION: HEART MASSAGE AND RECOVERY.

A REMARKABLE example of saving a patient's life after the circulation had failed, during an operation for the removal of tonsils and adenoids, by heart massage, is recorded by Mr. W. M. Mollison in the *British Journal of Children's Diseases* for March. It is remarkable for three reasons. One is on account of the length of time, estimated at 13 minutes, during which the heart stopped beating. In the published records of 13 successful cases of heart massage for a similar purpose which the author has been able to collect, this time-period was usually only two or three minutes, the longest being eight minutes, and, as he suggests, it is open to question whether the heart would not have recovered without the massage in such instances. The second unusual circumstance was that the region in which the operation was performed did not of itself facilitate massage; so that a separate and rapid incision into the abdomen was required in order that the hand, thrust up over the liver, could be applied to the heart, the diaphragm alone intervening. And lastly, interest attaches to the curious cerebral state which continued for some days after the operation. The patient was a boy aged 6 years. He was slight, but healthy in appearance. The anæsthetic, given on an open mask, was a mixture of chloroform, two parts, and ether, three parts. The left tonsil was removed; it was just after the right had been similarly dealt with that respiration ceased, cyanosis occurred, the heart stopped beating, and the pupils became dilated. The abdomen was opened five minutes later, after the ordinary means of resuscitation had been used and failed. The right hand, thrust between liver and diaphragm, easily felt the heart; it was motionless. Pressure was exerted upon the heart at a rate of about 90 squeezes a minute. For some moments there was no response; then some respiratory movements began and continued intermittently. Still there was no attempt at heart contractions. One c.c. of pituitrin was injected directly into the heart and massage renewed; after about 20 more squeezes the heart suddenly began beating strongly. Recovery followed. For the next seven days the boy was more or less unconscious. For ten days there was rigidity of the limbs or choreic movements. Frequently he cried out shrilly (meningitic cry); for 36 hours on one occasion screaming was almost continuous. For 12 days there was incontinence of fæces, and for 15 of urine too. On the tenth day he became very violent and tore his bedclothes. Improvement gradually followed and he made a perfect recovery. The recommendations, in view of this experience, which Mr. Mollison suggests are two: first, that heart massage should not be postponed too long, and, second, that massage ought always to be applied through an abdominal wound.

ANTHRAX IN MAN.

IN the *Journal of Agricultural Research* (vol. viii., No. 2, Washington) Messrs. A. Eichhorn, W. N. Berg, and R. A. Kelser, in a paper on "Immunity Studies on Anthrax Serum," state that considerable amounts of anthrax serum prepared with serum-globulin have been furnished for treatment of the disease in man with highly satisfactory results. Of the serum the curative dose is 40 c.c., administered subcutaneously in four or five places. After an interval of 24 hours a further injection of 25 c.c. may be given, repeated as often as necessary. Larger intravenous injections may be given in advanced cases. The dose of the globulin preparation is based on its proportional concentration, and is usually from 10 to 15 c.c., which can be safely given intravenously. With other types of protein absent the globulin preparation is superior to ordinary serum inasmuch as anaphylactic reaction is minimised. In a number of cases of anthrax in man treated at Bellevue Hospital, New York, it was found that a marked lowering of the temperature and reduction of the œdematous swelling followed the first injection of serum.

THE retirement will be announced shortly of Sir Arthur May, the Director-General of the Naval Medical Service, and we understand that the responsible duties which he has so ably performed will devolve upon Surgeon-General W. H. Norman, C.B.—an appointment which will be esteemed throughout the Service. Since May, 1914, Surgeon-General Norman has been in charge of the Plymouth Royal Naval Hospital.

THE QUESTION OF ECONOMY IN FOOD.

BY M. S. PEMBREY, M.A., M.D. OXON.,
LECTURER IN PHYSIOLOGY, GUY'S HOSPITAL.

IT is the duty of the medical profession to point out clearly the relation between an adequate supply of food and health and efficiency. It is a problem which has been before them for many years and has been investigated from many points of view by scientific men in this and other countries. The results give the clearest guidance in this time of crisis, but the Government have not formed a proper estimate of their value. An attempt will here be made to state clearly the results, which are not disputed, and to indicate the measures which should be employed to meet the restricted supply of food.

Food Requirements of the Body.

The combustion of foodstuffs is a characteristic of life, and in man only ceases with life itself. It is true that men may fast for 30 to 40 days without any fatal or very serious results, as the observations upon the professional fasting men have proved. Water they must have, and food they obtain by living upon their own living substance. This material consumed by a fasting man corresponds to foodstuffs which would yield 1500 to 2000 calories per day. The man is losing weight rapidly, soon becomes incapable of work, and unless the fast is broken will die. If, on the other hand, just sufficient food to maintain life be given, a man at rest in bed requires food with a fuel value of about 1800 calories per day to make good the daily loss, which is due to the "physiological work" of living. Even during the deepest sleep the body is always at work, the heart must continue to pump the blood, the muscles of the chest contract in breathing, and the glands elaborate their products. The two conditions just described give an estimate of the minimum needs of an adult.

The voluntary ration, 4 lb. bread, ¾ lb. sugar, and 2½ lb. meat per head per week, yields about 1200 calories per day, and when allowance is made for women and children is calculated to supply 2000 calories per man. It may therefore be considered a maintenance diet, and with the addition of other food will form an adequate diet for a man doing light work.

There are points of resemblance and also of difference between a man and a machine. No one expects to obtain work from a steam or petrol engine without a proportionate supply of fuel; the more work, the more fuel. There is always waste, and in respect of efficiency the engine is far behind the living body. The points of difference are enormous. The body is not only a transformer of energy, but effects its own repairs, becomes stronger with use, and even reproduces itself. The law of conservation of energy applies to man. For national efficiency the man who does essential muscular work must have a greater amount of food than the sedentary worker, and it matters not what may be their respective wages. The dietary which would be generous for a man or a horse doing no work would be slow starvation if he were forced to work hard each day. A system of rations, therefore, which pays no attention to occupation is absurd. In the following table of standards due to Atwater it will be seen that a man doing very hard work requires twice as much food as the man who does none.

Condition as regards muscular work.	Calories required per day.
None	2700
Light	3000
Moderate	3500
Hard	4500
Very hard	5500

These values are found to be necessary, as the following examples of daily rations will show.

As regards these data it is true that allowance has not been made in all cases for waste; but against this must be set the increase due to the food which is bought to supplement the ration.

[1] Part of a lecture on "The Restricted Supply of Food: its Relation to Health and Efficiency," delivered to the Royal Sanitary Institute, April 25th, 1917.

Examples of Daily Rations.

—	Protein in grms.	Fat in grms.	Carbohydrate in grms.	Calories, total.
Food supplied free, seamen, R.N.	91	48	406	2585*
,, ,, ,, boys, ,,	107	69	406	2745*
,, consumed by seamen, ,,	176	—	—	4080
Food supplied free to four British Regiments	133	115	424	3369
U.S.A. Army (peace ration)	157	140	603	4179
Ordinary prisoners, Scotland, light work, mostly sedentary	133	35	536	3115
U.S.A. labourers at hard muscular work	177	—	—	6485
U.S.A., very poor working people	69	—	—	2275
Japan, labourers	118	—	—	4415
Duke of York's Royal Military School (young men)	157	206	472	4514
Boys 9–14 years of age at English Public School	123	97	430	3400
Children over 8 years of age in L.C.C. School	88	66	377	2515

* Allowed also 4d. a day to buy extra food.

A system of rations may be necessary under certain conditions, but it is an uneconomical one, and on physiological grounds is unsound. It allows little or no free choice of food and is not readily adjusted to the various factors which determine the need of different qualities or quantities of food. Likes and dislikes are expressions of physiological needs. Healthy men are animals, and when they work steadily and well do not overfeed, even if they have free choice of abundant food. This is well shown by the fact that the average weight of the body remains very constant over long periods, it may be years, in the healthy and active adult, and likewise, as would be expected, the average consumption of food and the output of work.

The limitation of the system of rations is shown by the presence of dry canteens in the Services, the numerous eating-houses in garrison towns and ports, the parcels from home and the "tuck" shops for school-children. Rigid rations, if they are adequate for a large number of men, must lead to waste, for in no other way can allowance be made for various physiological needs.

Regulation of the Supply of Food.

The supply of food may be inadequate in quality, quantity, or in both. The foodstuffs which at the present time must be considered are wheat, meat, milk, sugar, and potatoes. A deficiency in one form of food may be covered by another article which is available. Substitution can by physiological processes be carried further than is possible by the chemist. In the living body sugar and fat can be formed from starch in the food, and the reverse processes are also possible. As a general law it may be stated that as sources of energy the foodstuffs can replace each other according to their values as producers of heat, thus the following are isodynamic quantities:—100 grms. fat, 232 starch, 234 cane sugar, and 243 dried meat. In practice an important factor is the relative cost of the different foodstuffs, which will be considered later.

For a condition of health and efficiency the food should be more than enough to cover the outgoings in the form of heat and work; a balance upon the right side is useful in times of extra or special demand. This is especially the case in the young, for if this balance is not available healthy growth is impossible. Unsuitable food, inadequate in quality or quantity or both, is recognised as one of the chief causes of the terrible mortality of children. The resistance to disease is lowered by unfeeding and lack of exercise, and there are reasons to suspect that the economy of food in schools all over the country has had, and is having, a bad effect upon the health and vigour of the children.

Many men, women, and children are doing hard muscular work which they never did in times of peace; they must have more food if they are to be efficient, and cheap food if they are to save money as they are urged by the Government.

The ideal is a liberal supply of food with free choice. This may be impossible, and the question arises, How is the supply to be regulated in the interests of the nation? The Government have wisely avoided thus far a compulsory ration, and have made attempts at control by fixed prices

and other methods. The laws of nutrition will still be in force whatever this or any other Government may do, and wisdom would lie in the recognition of the supreme power of natural law. If one foodstuff is deficient a substitute can be found in others, owing to the powers of adaptation of the body and its capacity of converting some forms of food into others. Moreover, the body as an engine can use different kinds of fuel. If coal fails steam may be generated in the engines of a ship by oil, wood, or in emergencies even by burning parts of the ship itself. From this point of view the scarcity of wheat must be considered.

Cereals.—Other corn can take the place of wheat and should be used for this purpose. There is barley and malt used for the production of alcohol, an inefficient form of food at the best and a deadly poison in excess. According to the Food Controller there are 1,000,000 quarters of brewers' malt in this country at the present time; it is not to be used for food, but for the production of beer. The convictions for drunkenness in the Metropolitan Police district and the City for the first quarter of this year were 6176. The Food Controller says that the food value of beer is not disputed, and the Government does not consider it is necessary to save the millions of quarters of barley, malt, and other foodstuffs which are used in the manufacture of alcohol. There may be reasons of policy for allowing alcohol to men in the Services or employed in some essential occupations, but there is none for its widespread consumption. An underfed nation is more dangerous and inefficient than well-fed men, some of whom are aggrieved because they cannot obtain their beer.

Oats can be used as a substitute for wheat, but there is difficulty in obtaining a ready supply; the oats are being kept for the horses. A horse may consume 40 to 80 lb. of oats per week, and hunters and racehorses receive the best. Hunting and racing have been and are allowed; only now is the Government taking steps to consider whether savings in this respect should be effected in the interests of the food-supply of the people. There are thousands of hunters, racehorses, riding horses, and carriage horses used only for pleasure in this country; the consumption of oats, maize, beans, hay, straw, and carrots by these animals must be enormous. With the exception of the hay and straw, which would be useful for cows, all these tons of food could be used by man himself; the objection that the horses are needed as a reserve for breeding and for the Army has no force, for all of these animals could be kept at grass, and under these conditions would liberate many men for essential work.

The percentage composition of these cereals is as follows:

	Protein.	Fat.	Carbohydrate.	Fuel value per lb. Calories.
Wheat flour... ...	8·3	1·0	73·5	1615
Barley, pearled...	6·6	1·0	76·1	1630
Maize flour	5·8	1·2	76·3	1625
Oatmeal...	13·4	6·6	65·2	1795

All of these substances have been used, even in times of peace, as substitutes for wheat. In some respects oats are a better food than wheat, and the fuel value of one pound is greater than the total for one day of the voluntary ration suggested by the Food Controller. A horse eating daily 10 lb. of oats consumes an amount of cereal food which would be sufficient for 10 to 20 men.

Sugar and Potatoes.—Sugar and potatoes are foods which were introduced into this country in times relatively recent, and it is obvious that they are not so essential as some people imagine. The children should have first claim on sugar, and they could also obtain milk-sugar in milk and malt-sugar in malt, besides those essential substances known as "vitamines." Substitutes for potatoes can be found in other vegetables and the carbohydrates of cereals.

Milk.—The supply of milk is another difficulty, and it has received the attention of the Government. A maximum price has been fixed for the retailer and the producer; the farmers have been selling their cows and giving up the production of milk, notwithstanding the fact that it was a very lucrative business, according to many writers to the daily press. For young children, invalids, and our sick and wounded soldiers milk is a food for which no efficient substitute can be found. During the spring and summer months there may be no serious shortage, for those are the best months, when the cows are at grass, the supply is large and feeding is cheap. There is a shortage at the present time and the coming autumn and winter will show the effects of the reduction of the milking herds. Action, however, must be taken now. Heifers cannot be made into milch cows under ten months. The Government have revised their "milk orders"; the farmers ask for the recall of these orders. In any case a reserve of cows could be provided by the end of next winter if the Government purchased at once numerous heifers and turned them out to graze with young bulls on land owned or taken over by the Government. Even if money were an object the transaction would be probably a very profitable one. A supply of milk should be safeguarded and its cost should be low for the sake of the children, even if it be necessary for the State to give a subsidy.

Other Measures.

If the scarcity of food is general, the true remedy lies in an extension of the supply. Action has been taken at last, pasture has been ploughed up, but the highly fertile ground of the hop-gardens will apparently in many cases still grow hops for beer, instead of corn or potatoes for bread. The hop-growers should have compensation if necessary, but food they should grow, for it is food which is needed.

Another source of food which is undeveloped is the salt and fresh water fish, but this, owing to the supply of cattle, is not so urgent as the question of cereals.

If the cost of food continues to rise difficulties of a serious kind must occur, for a strong man is liable to become dangerous when he is hungry. A corresponding rise in wages does not meet every difficulty. The wage is not adjusted to the size of the breadwinner's family. A great relief and a true safeguard for the present and the future would be the free supply of dinner and tea to school-children; the necessary machinery is simple, if the expense is a general one borne by the State. The health of the future generation could be secured, a great burden would be taken from many hard-working and deserving parents. Foodstuffs which the labouring classes cannot obtain readily or cook could be used in these free meals, and bread would be saved. There would be no danger that the children would be overfed; healthy children are active and growing, and the law of averages as regards food would hold good.

Petty orders, such as the prohibition of Sunday-school treats and cakes, show no appreciation of the laws of nutrition and cause an amount of irritation out of all proportion to the result obtained. The owner of poultry is not allowed corn; the hen does not return in eggs the food value of the food consumed; no animal ever did or ever will, for it must have some for its life, but when allowance is made for the consumption of refuse the hen is economical. The owner of race-horses, hunters, and other horses used for pleasure is allowed in unlimited quantities the very best corn he can buy; he takes the food from the mouths of the poor by outbidding them in the purchase of some of the best articles of food and at a time when there is a great scarcity.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Maintenance of Irish Asylums.

A SERIOUS financial position has arisen with regard to the Government grant for the maintenance of Irish asylums. The grant has come from an account known as the Local Taxation Account, and the amount payable has been practically stereotyped, regardless of the increasing expenditure of the asylums. At the time the grant was fixed it was sufficient to bear about half the cost of maintenance of asylum patients, but for several years prior to the war this cost was gradually increasing. With the present rate of prices the cost of maintenance has more than doubled since 1914, while the Local Taxation Account, owing to the falling-off in the revenue from licences and other local duties, is no longer able to bear even the stereotyped charge. Up to 1899 the State grant and local rates each contributed about 4*s*. per lunatic per week, whereas it is calculated that in the present year the State will only pay 3*s* 6*d*. per head, and the balance, at least 13*s*., must be borne by local rates. The asylums are not alone in misfortune owing to the failure of the Local Taxation Account. Grants are also paid toward

the salaries of Poor-law medical officers and workhouse nurses and of workhouse school teachers, toward the cost of medicines for Poor-law patients, and for some other purposes. All these will suffer, but not to the same extent as the asylums.

The Public Health of Belfast.

That the condition of Belfast from a public health point of view is anything but satisfactory at present is clear to anyone reading the articles appearing in the local papers and also from a perusal of the discussion which occurred at the monthly meeting of the city council on May 1st. Between March 18th and April 21st of this year the average annual death-rate from all causes was 21·8, while in the corresponding period of 1916 it was 20·7; and 188 cases of infectious disease were notified, compared with 115 in the previous five weeks and 169 in the corresponding period of 1916. Altogether 37 cases of typhus had occurred in the recent epidemic, while upwards of 100 new cases of typhoid have been notified during the eight weeks up to the middle of April. The chairman of the Public Health Committee was unable to assign any cause for the origin of the typhus outbreak beyond the fact that ships came to Belfast from foreign ports, which might have brought the disease to the city—an explanation sufficient to cover the occurrence of any form of infectious disease in any maritime town at all times and seasons. As to the typhoid, in the district principally affected—Ballymacarrett—the health committee put forward as an explanation the eating of shell-fish, a view medical expert opinion in Belfast would certainly not endorse. Nothing was said as to insanitary domestic conditions. Then one of the aldermen of the city council made a very severe attack on the corporation scheme for dealing with tuberculosis, which began in May, 1913. The scheme was, he said, costing £31,600 a year now, instead of £15,000 as formerly, without obtaining any results, and he mentioned that in the first quarter of 1917 the death-rate from tuberculosis had exceeded anything experienced for the past 15 years. In 1911 the deaths from phthisis in Belfast were 802, while in 1916 they were 828, and during the three months from Dec. 16th, 1916, to March 16th, 1917, 290 deaths occurred from pulmonary tuberculosis, a figure much above the average. The monthly figures were respectively 93, 85, and 112. In 1914, from the middle of January to the middle of March, 139 deaths took place from phthisis, while during the same period in 1917 there were 197. The corporation scheme for dealing with infantile mortality has not yet been launched, and although £32,000 a year are being paid for street cleansing, not a municipal water-cart was used until last week, and dust, full of microbes, was being blown into the houses. In a word, notwithstanding that more money is being spent, the public health of Belfast is not improving, and no real scientific attempt is being made to grapple with the great questions of public health that are now being considered in England and Scotland.

Belfast and the War Office.

The action of the War Office in dealing with Irish medical schools and with Irish doctors requires some explanation, as is apparent from what appears in THE LANCET of May 5th, p. 704, where, in reference to a Dublin hospital for France, it is said a similar offer on more than one previous occasion was refused when made by Dublin, and also when offered by Belfast in 1915, and by Cork more recently. Not only are these facts accurate, but it may be added that again last week Sir Alfred Keogh, Director-General A.M.S., refused a second offer from the medical profession in Belfast. As a result, the president of the Ulster Medical Society has written Lord Derby, asking him to explain his letter urgently calling for doctors, with this refusal on the part of the heads of the Royal Army Medical Corps, at the War Office to accept the second offer from the members of the Belfast Medical School. Another matter causing great annoyance is the fact that experienced hospital surgeons, who on high patriotic grounds have offered their services, are told that they can join with the rank of their pupils a few days qualified, and go to a camp to be trained, when some of them thus treated have actually been doing all the operative work at the Belfast Military Hospital. At the same time the ranks of lieutenant-colonel and captain are given to others on their first appointment as temporary medical officers of the Royal Army Medical Corps.

"Audi alteram partem."

THE NEGLECT OF VACCINATION.

To the Editor of THE LANCET.

SIR,—The Local Government Board has recently inquired from the local authorities as to the isolation accommodation for small-pox cases, and the replies generally in the West of England cannot, it seems, be described as satisfactory. This is to be much regretted, as owing to the decrease in vaccination it is essential that adequate isolation should be provided. The neglect of vaccination has probably not had the attention it demands, and this is the feeling of public vaccinators in most districts. In several towns in the West the number of conscientious exemptions exceed largely the number of successful vaccinations. It would be as well to have the term conscientious objection more clearly defined, often it is only ignorance that is implied when the expression is used. A man told me that he never had his children vaccinated; he had a "conscientious objection" to the operation, as he did "not want matter put into his children's arms." This parent was a member of a board of guardians, and had voted against vaccination whenever that subject was discussed at the meetings. Legal proceedings are practically never taken against parents for neglecting to have their children vaccinated, and perhaps this is wise, for the delinquents have often been fined a few coppers, and these fines are paid by the antivaccination societies.

The operation of vaccination is performed differently by many medical men; the public vaccinator has to make four marks, the private practitioner has liberty to make the number he prefers. In some centres there are one or two medical men who vaccinate in one place, and they vaccinate hundreds of children annually. I have seen the resultant scars of some of these cases, and they are almost microscopical in size. These vaccinations might be described as evasions of the law, and the protection conferred by them against small-pox must be extremely limited. After the war the whole subject of the performance of vaccination will have to be gone into, for the annual returns show a large decrease every year in the number of successful cases. The question would then be discussed as to whether any certificate of successful vaccination should be accepted unless it states the number of marks obtained, this number to be fixed by the authorities.

Another point open for debate is whether the public vaccinator should not be abolished, and the parents allowed to have their own medical attendant to perform the operation, the fees being paid by the State. This would make vaccination more popular with the parents, as the family practitioner would be preferred to the public official.

Doubtless several changes will occur in the administration of the Vaccination Acts, and if vaccination could be carried out more efficiently and revaccination enforced, the isolation accommodation at present available would be probably more than sufficient. I am, Sir, yours faithfully,

Lyme Regis, May 4th, 1917. JAMES D. STAPLE.

THE TECHNIQUE OF LUMBAR PUNCTURE.

To the Editor of THE LANCET.

SIR,—The contretemps which Mr. Sheffield Neave has experienced (THE LANCET, May 5th) must be, I think, very unusual, and it is remarkable that it has occurred in his practice three times. It is unlikely that he has met with three cases of congenital abnormality of the vertebral column, which have required lumbar puncture. It is also unlikely that he has struck an intervertebral disc without blunting his needle considerably. It is more likely that he underestimated the distance across the bony canal. I entirely agree with him in his remark about the value of revolving the needle in order to establish or increase the flow of fluid. Another device for the same purpose is to make the patient cough, or, if he is sitting up, to get him to raise his head slightly. It is useful to make a practice of operating below the fourth lumbar spine. Frequently when blood is met with here the fluid will be clear at the higher levels. This, no doubt, is

more often the case when the patient is sitting up on a stool. I always use a syringe as a handle for the needle. It serves also to wash the needle through when a fresh puncture is necessary and at the completion of the operation. Several sterilised test-tubes should always be at hand. It must be remembered that a little blood does not interfere at all with the cytological examination of the fluid or of the Wassermann reaction. In the former case the necessary adjustment can be made readily by simple arithmetic; for the Wassermann reaction the pathologist requires to have the fact that the fluid contained blood in his mind when he reads off the result of the test. To my mind the "Barker" needles are needlessly large. Fine needles of platinum-iridium, which I first saw used by Colonel Purves Stewart five years ago, make lumbar puncture practically a painless operation. The skin is sprayed with ethyl chloride. Over and over again patients have told me that they felt no pain whatever, and a medical man, whom I punctured recently, told me at the end of the operation that he did not know that I had commenced. The fineness of the needles has, in my hands, offered no difficulty in the case of intrathecal injections. My two needles, which are in use almost daily, are those which I bought five years ago. About once a year they require straightening out. Personal attention to one's needles is essential.

The high incidence of neurological syphilis in the Navy brings with it a large experience of lumbar puncture work. In the last ten months at Haslar, for instance, we have done some 250 lumbar punctures in the neurological department. In only one case was the resulting discomfort sufficient to cause the patient to ask that the operation might not be repeated. I agree with Dr. T. J. Horder (THE LANCET, April 28th) that a "dry puncture" is another word for an unsuccessful operation. With reference to Surgeon F. A. Williamson's dilemma (THE LANCET, April 21st), surely a "mistake in diagnosis" should not occur if the cytology of the fluid is examined. This is of far greater importance than the estimation of the pressure of the fluid. The determination and the enumeration of cells requires only a bottle of stain, a graduated pipette, an ordinary hæmocytometer, and a microscope with a 1/6th inch objective.

I am, Sir, yours faithfully,

HILDRED CARLILL, M.A., M.D. Cantab., M.R.C.P. Lond.,
Neurologist to the Royal Naval Hospital, Haslar.

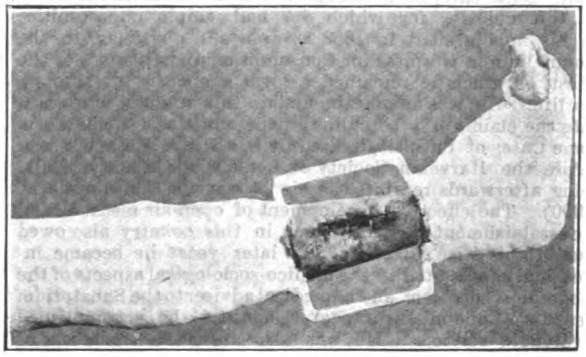
R.N. Hospital, Haslar, May 6th, 1917.

THE USE OF STATISTICS IN MEDICINE.

To the Editor of THE LANCET.

SIR,—This is not the time, nor can you provide the space, for a discussion of the proper use of statistical methods. The "wise sayings" of Sir Almroth Wright which you endorse have already been commented upon at length by me in your columns (January, 1913). But I do venture to ask, in all seriousness, whether this is the time once more to trot out that pantomime elephant, the imaginary "statistician," who insists on masses of heterogeneous data and refuses to pay attention to small groups of homogeneous observations and to contrast that comic animal with the expert (also imaginary) who can deduce absolute truth from half a dozen intensively studied cases.

I do not blame your contributor for not knowing that for several years English statisticians have been at work on the problem of the small sample, any more than I blame the publicity department of the Food Ministry for issuing guesses as to the quantity of food wasted in private families without studying the exact investigations of this point published 17 years ago by Atwater's collaborators; nobody can be expected to read the literature of a subject upon which he means to advise the public—it would bias him. But if I go to the expense of having six absolutely true dice cut, and if on the first trial they all throw a 5, and I at once recommend the gambling public to put their money on 5 in future dicing, I wonder whether your contributor will contrast me advantageously with Weldon and other statisticians who went to the trouble of making thousands of tosses with the ordinary dice of commerce, and whether he will draw that moral of his—viz., when a shorter and a longer way are open, it is not well to choose the longer. On the whole, I do not think he will. But if I were to say that a profound knowledge of the peculiarities of dice, *my* dice, had satisfied me that it really was a certainty that the 5 would turn up and that other observations inconsistent with this view were due to want of technical knowledge on the part of the observer, he would no doubt take my word. Perhaps the gambler would, too, and perhaps he would not be *quite* satisfied in the long run.



I am, Sir, yours faithfully,

Lister Institute, S.W., May 5th, 1917. M. GREENWOOD, Jr.

BRIDGED PLASTER SPLINTING.

To the Editor of THE LANCET.

SIR,—Referring to the method of plaster splinting described by Captain George Davis in THE LANCET of Feb. 24th I may say that this method of applying plaster has been in use in Boston, Mass., for a number of years and it was when I was a student in Boston that I learned this method. It was used extensively at the American Ambulance in Paris by Dr. Osgood, of Boston, when he was on service there. I have referred to bridged plaster in my recent book on Military Surgery, and the appended photograph shows the splint in use.—I am, Sir, yours faithfully,

Bridged plaster splint applied for an infected gunshot wound of the leg in order to facilitate dressing and at the same time immobilise the fragments.

D. PEARCE PENHALLOW,
Chief Surgeon, American Women's War Hospital.

Oldway House, Paignton, South Devon, April 14th, 1917.

A SIMPLE METHOD OF APPROXIMATING THE EDGES OF WOUNDS.

To the Editor of THE LANCET.

SIR,—I venture to suggest a mode of uniting the edges of wounds which is original, though perhaps not new. It is especially useful with children and in cuts or operations about the face where stitch marks are sometimes more noticeable than the actual scar of the wound.

After preparing the wound, take a suitable number of pieces of silk thread about 4 in. long, each with a knot at the end, and arrange them across the wound just where stitches would be placed. Then fasten down the knotted ends with strapping ¾ in. broad, with its edge half an inch from the wound, and turn the loose ends back. Having similarly prepared the other side, it only remains to draw the edges of the wound together and tie the ends in pairs. For small operations one has time to adjust the silk ends and strapping ready for use, and the former may be passed through the strapping to make it even more secure. I have always used Johnson's adhesive strapping, which keeps the silk quite firm, only the latter must not be wet.

This method might be used for larger wounds to supplement stitches, or to replace those which have given way, or to relieve tension. I am, Sir, yours faithfully,

GEORGE A. BALLINGALL.

St. Leonards-on-Sea, May 2nd, 1917.

THE American National League of Nursing Education has elected Mrs. Bedford Fenwick as their first honorary member in recognition of her labours for the higher education and registration of nurses. The League is composed of all the leading superintendents of training schools for nurses in the United States.

Obituary.

JOHN EDWARD SQUIRE, C.B., M.D. LOND., F.R.C.P. LOND., D.P.H. CAMB.,

CONSULTING PHYSICIAN, MOUNT VERNON HOSPITAL FOR CONSUMPTION, ETC.

WITH the death of Dr. J. E. Squire at his house in London on May 2nd, at the age of 62, the medical profession is the poorer by the loss of one who may justly rank with the pioneers in the modern study and hygienic management of tuberculosis.

John Edward Squire was born in 1855, the son of the late Dr. William Squire, and was brought up in a medical atmosphere with the best of professional traditions. He was educated at University College, London, obtaining his M.B. Lond. in 1881 and his M.D. in the following year, when he became house physician at University College Hospital. Quite early in his career he was attracted to the study of tuberculosis, for which he had ample opportunities on his appointment in 1882 as assistant physician to the Mount Vernon Hospital for Consumption and Diseases of the Chest, of which he remained a loyal supporter all through his life. He was among the first in this country to investigate the claims of tuberculin, a paper entitled "Remarks on Some Cases of Phthisis, treated by Dr. Koch's Method," read before the Harveian Society of London in January, 1891, being afterwards reprinted in his "Essays on Consumption" (1900). The effective development of open-air methods and the establishment of sanatoriums in this country also owed much to his wise advocacy. In later years he became increasingly interested in the medico-sociological aspects of the tuberculosis problem, and as medical adviser to the Sanatorium Benefits (London Insurance) Committee he accomplished invaluable service. He was also an active member of Council of the National Association for the Prevention of Consumption, and a corresponding member of the International Association for the Prevention of Tuberculosis.

Dr. Squire construed his civic duties in a wide sense. In 1885 he served as senior medical officer under the Red Cross in the Soudan Campaign, obtaining the Egyptian medal and the Khedive's bronze star. From 1898 to 1904 he devoted much time and energy to the development of London companies of the R.A.M.C., and on retiring was granted the C.B. and a Volunteer decoration. This service gave him the necessary experience to write a useful manual entitled "Medical Hints to Medical Officers temporarily employed with Troops," issued in 1915 as an Oxford War Primer, his last published writing. Among other awards he received the Queen Victoria Jubilee medal, the King Edward VII. Coronation medal, and King George V. Coronation medal. He was also a Knight of Grace of the Order of St. John of Jerusalem. In addition to the books already mentioned Dr. Squire made many contributions to contemporary medical literature, of which his "Hygienic Prevention of Consumption" (1893) and "Preservation of Health" (1900) attracted most attention. A valuable paper on the "Incidence of Tuberculosis in Children" appeared in our columns in 1910.

One of his colleagues and personal friends writes :—

For over 20 years it has been my privilege to have been closely associated with the late Dr. Squire as a colleague and in private life. He was one of the most hard-working and energetic men whom I have ever met. A glance at the number and variety of the appointments which he held from time to time, and to all of which he devoted himself with self-sacrificing zeal, will show that he was a man who sought a multiplicity of duties, though his name is associated chiefly with tuberculosis and though in later years his professional work was almost entirely in this direction. For example, he took a foremost part for many years in the organisation of the R.A.M.C. (T.) and was, I believe, on his retirement the senior officer in that branch of the service. At the time of the South African War he was largely instrumental in organising and sending out a Territorial Unit, for which work, among other things, he received the C.B. Of late years much of his time was devoted to the activities of the London Insurance Committee, where these had reference to the tuberculosis and sanatorium benefits under the Act. Here his talent for organisation was of the greatest service, for the general campaign for the prevention of consumption was one of his most profound interests. He took a very active part in the foundation of the St. Marylebone Dispensary, of which he was chairman for some years, and recently had been working very hard over the starting of a scheme for the after-treatment of the tuberculous when they had been discharged from hospitals and sanatoria. When it was pointed out to him that, in spite of all his work, his name did not appear prominently in the matter, it was characteristic of him to reply, "That does not matter so long as the work gets done," and it was a source of the greatest gratification to him to see the practical progress that was being made. He was a most conscientious man, and, perhaps, incurred the charge of being changeable from the fact that he examined every problem closely, and was prepared to revise his judgment. He was not an accessible man; there was a certain aloofness and even brusqueness in his manner upon occasion, and these two characteristics, great conscientiousness and a kind of shyness, led to his being often misunderstood by those who only knew him slightly. He was really a very sensitive and highly-strung man, with very strong feelings and affections. The loss of his only son at Neuve Chapelle was a blow from which he had not recovered when his own time to pass over came suddenly in the midst of his labours. His memory will always be held in affectionate esteem and respect by all those who really had his friendship.

Concerning his personal qualities, another of his colleagues at the Mount Vernon Hospital writes :—

Dr. Squire possessed a genius for taking pains. Cautious, patient, reliable as a clinician, he was an able organiser and a tactful administrator. As a teacher he was lucid in exposition and ever ready to devote time and thought to the consideration of essential details. He was, as a result, much in demand as a lecturer. By his premature death medical science has sustained a heavy loss and the health service of the community has been deprived of a man who gave his best for the sake of the people. He died as he would have wished, in harness, a valued companion and trusted counsellor to the last.

Dr. Squire married in 1894 Mary Lily Youngman. His widow and two daughters survive him, and for them the deepest sympathy will be felt.

THE LATE MR. F. W. FOWKE.—On April 27th there passed away at his residence, Byfield, Northants, at the age of 73, Frederick William Fowke, M.R.C.S. Eng., M.R.C.P. Edin., L.S.A. Lond., who had, until his retirement in 1900, been for many years a highly trusted practitioner of the neighbourhood. Born in 1844, the eldest son of the late Frederick Gustavus Fowke, of Charlwelton, he was educated at Leamington, later qualifying as a medical man after studentship at Guy's Hospital. He practised in Byfield from his hospital days, and his services were widely known and valued among all classes. He leaves a widow and three sons.

URBAN VITAL STATISTICS.

(Week ended May 5th, 1917.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 17,000,000 persons, the annual rate of mortality was 15·7, against 18·4 and 16·7 per 1000 in the two preceding weeks. In London, with a population exceeding 4,000,000 persons, the death-rate was 15·4, or 1·4 per 1000 below that recorded in the previous week; among the remaining towns the rates ranged from 7·5 in Wallasey, 7·9 in Eastbourne, and 8·0 in Ealing to 23·5 in Middlesbrough, 23·6 in Halifax, and 25·5 in Stockton-on-Tees. The principal epidemic diseases caused 450 deaths, which corresponded to an annual rate of 1·4 per 1000, and included 280 from measles, 64 from infantile diarrhœa, 63 from whooping-cough, 33 from diphtheria, 7 from scarlet fever, and 3 from enteric fever. The deaths from measles were slightly in excess of the number in the previous week, and caused the highest annual death-rates of 3·4 in Salford, 3·6 in Middlesbrough and in Sunderland, 3·8 in South Shields and 6·2 in West Bromwich. The 739 cases of scarlet fever and 1203 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 19 above and 9 below the numbers remaining at the end of the previous week. Of the 5119 deaths from all causes in the 96 towns, 158 resulted from violence. The causes of 39 deaths were uncertified, and included 10 in Birmingham and 4 each in Liverpool and Sunderland, but not one in London.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual death-rate was equal to 17·2, against 18·1 and 18·4 per 1000 in the two preceding weeks. The 399 deaths in Glasgow corresponded to an annual rate of 18·6 per 1000, and included 38 from whooping-cough, 33 from measles, 3 from diphtheria, and 1 from scarlet fever. The 120 deaths in Edinburgh were equal to an annual rate of 18·9 per 1000, and included 25 from measles, 7 from whooping-cough, 2 from infantile diarrhœa, and 1 from diphtheria.

Irish Towns.—The 163 deaths in Dublin were equal to a rate of 22·0 or 1·6 per 1000 above that recorded in the previous week, and included 8 from measles, 3 from whooping-cough, and 1 from diphtheria. The 125 deaths in Belfast corresponded to an annual rate of 16·6 per 1000, and included 3 each from enteric fever and infantile diarrhœa, and 1 each from scarlet fever and typhus.

The War.

THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue:—

Killed.

Capt. E. Harrison, R.A.M.C., attached Gloucester Regiment, was educated at Cambridge and at St. Bartholomew's Hospital, London, and qualified in 1904. He held appointments at the Hospital for Women, Soho, London, and at the Scarborough Hospital, and was in practice at Leicester prior to joining the R.A.M.C.

Lieut.-Col. (acting Col.) F. A. Symons, R.A.M.C., C.M.G., D.S.O., A.D.M.S., qualified at Edinburgh in 1891. He joined the R.A.M.C. in 1893 and was promoted Lieutenant-Colonel in 1915. He saw service in the South African War, taking part in the relief of Ladysmith, and received the Queen's medal with three clasps. He was awarded the D.S.O. in February, 1915 (THE LANCET, Feb. 27th, 1915, p. 469), and the C.M.G. at the close of last year (THE LANCET, Jan. 6th, 1917, p. 37).

Capt. P. E. Lones, R.A.M.C., was a student at University College Hospital and qualified in 1915, and thereupon joined up.

Died of Wounds.

Capt. J. B. Tackaberry, I.M.S., was a student at Middlesex Hospital and qualified in 1909. He joined the Indian Medical Service in 1910 and was promoted Captain in 1913.

Surgeon-Major A. H. Palmer, Staffordshire Yeomanry, was educated at Birmingham University and at Guy's Hospital, London, and qualified in 1895. He had been associated for some years with the Yeomanry, and died at Cairo on May 2nd.

Lieut. J. A. S. Burges, qualified at Glasgow in 1910, and held appointments at the Consumption Sanatorium, Bridge of Weir, and at the Glasgow Western Infirmary and the Glasgow Maternity and Women's Hospital. Prior to joining the R.A.M.C. he was in practice at Carronshore, Stirlingshire, and was medical officer of the parish of Airth.

Died as Prisoner in Turkish Hands.

Capt. K. K. Mukerji, I.M.S.

Missing, believed Drowned.

Lieut. J. Marshall, R.A.M.C., was educated at Edinburgh University and qualified in 1908. He was at one time house surgeon at the Darlington Hospital and later was in practice at Lancaster. Before joining the R.A.M.C. just recently he was on the staff of the Beaufort Military Hospital, Bristol.

Lieut. J. Rae, R.A.M.C., was educated at Aberdeen University and at University College, London, and qualified in 1909. He held appointments at the Cheltenham General Hospital, at the Connaught Hospital, Aldershot, and at the Park Hospital for Children, and was on the staff of the 1st Birmingham War Hospital before joining the R.A.M.C. in February last. He had made several contributions to medical and to other literature.

Lieut. M. W. Danzig, R.A.M.C., came from South Africa and qualified at Edinburgh in 1915, and joined the R.A.M.C. so recently as March last.

Lieut.-Col. A. C. Fox, D.S.O., R.A.M.C., was a student at the London Hospital and qualified in 1891. He joined the R.A.M.C. in 1894 and was gazetted Captain in 1897 and Lieutenant-Colonel in 1915. He was awarded the D.S.O. in February, 1915 (THE LANCET, Feb. 27th, 1915, p. 469).

Lieut. W. Grier, R.A.M.C., was educated at Glasgow University and qualified in 1905. He held appointments at the Eye Infirmary, at the Western Infirmary, and at the Maternity Hospital, Glasgow, and was in practice at Barrhead prior to joining the R.A.M.C. in the early part of this year.

Lieut. W. T. Harris, R.A.M.C.

Lieut. J. G. B. Smith, R.A.M.C., was a student at St. Bartholomew's Hospital, London, and qualified in 1915. He joined up quite recently.

Lieut. R. Stewart, R.A.M.C.

Wounded.

Capt. H. E. Creswell, R.A.M.C., attached K.R.R.C.
Capt. W. T. Collier, R.A.M.C.
Capt. R. H. MacDonald, Canadian A.M.C.
Capt. A. H. Wallace, Canadian A.M.C.
Capt. H. C. Wallace, Canadian A.M.C.
Capt. G. B. Lowe, Australian A.M.C.
Capt. F. E. S. Willis, R.A.M.C.
Capt. J. Fraser, M.C., R.A.M.C. attached Devon Regt.

DEATHS AMONG THE SONS OF MEDICAL MEN.

The following sons of medical men must be added to our lists of those who have fallen during the war:—

Lieut. J. L. Fowlie, Highland Light Infantry, elder son of Dr. P. Fowlie, of Singapore.

Second Lieut. D. N. O'N. Humphrey-Davy, Hampshire Regiment, younger son of Dr. A. Humphrey-Davy, of Bournemouth.

Capt. L. Profeit, King's Shropshire Light Infantry, youngest surviving son of the late Dr. A. Profeit, Commissioner to Queen Victoria at Balmoral.

Second Lieut. H. W. F. Cooper, Royal Fusiliers, only child of the late Mr. T. H. Cooper, M.R.C.S., of Hampstead, London.

Surgeon-Major A. H. Palmer, Staffordshire Yeomanry, eldest son of Dr. C. Palmer, of Burton-on-Trent.

Capt. G. L. Pagan, Royal Scots, son of the late Dr. Pagan, of Bothwell, Lanarkshire.

Capt. P. A. Hill, South Wales Borderers, only son of Col. P. E. Hill, A.M.S., of Crickhowell, Breconshire.

Second Lieut. G. H. Mapleson, Queen's Royal West Surrey Regt., youngest son of the late Dr. H. T. Mapleson, of Nottingham-place, London.

Lieut. W. D. L. Purves, East Lancashire Regt., youngest son of Dr. W. L. Purves of Stratford-place, London.

Lieut.-Col. M. E. McConaghey, D.S.O., Royal Scots Fusiliers, second son of the late Col. J. McConaghey, R.A.M.C.

THE HONOURS LIST.

The following award to a medical officer is announced:—

C.M.G.

Lt.-Col. Henry Arthur Powell, Australian A.M.C.

FOREIGN DECORATIONS.

By the President of the French Republic.

Legion d'Honneur.—Croix de Chevalier: Capt. V. B. Green-Armytage, I.M.S.; Lt.-Col. A. Mignault, Canadian A.M.C. *Croix d'Officier:* Col. H. D. Rowan, A.M.S.

Croix de Guerre.—Capt. A. C. Armstrong, Canadian A.M.C.; Temp. Capt. H. L. G. Hughes, D.S.O., R.A.M.C.; Temp. Capt. B. B. Noble, R.A.M.C.; Temp. Capt. R. R. Scott, R.A.M.C.; Temp. Capt. (temp. Maj.) A. G. Whitehorne-Cole, R.A.M.C.; Maj. H. H. Woollard, Australian A.M.C.; Temp. Lieut. St. J. D. Buxton, R.A.M.C.; Temp. Capt. K. G. Fraser, R.A.M.C.; Temp. Capt. W. A. L. H. Henderson, R.A.M.C.

THE PARIS CONFERENCE ON THE WAR CRIPPLE.

The proceedings of this inter-Allied conference opened on Tuesday with a *séance solennelle* at the Grand Palais, attended by the President of the French Republic. The delegates of the Allied Governments are as follows:—

Great Britain: Sir A. Keogh, G.C.B.; Fleet-Surgeon Percy H. Boyden, R.N.

Canada: Lieutenant-Colonel F. G. Finlay, C.A.M.C.

Italy: Professor Commandore E. Burci, Dr. Chevalier Guido Mendès.

Roumania: Dr. Marinesco.

Russia: M. le Chamtellan Bereznikow, Russian Red Cross; Professor Polienow.

Serbia: Colonel V. Soubotitch, Director-General Surgical Service of Serbian Army; M. Sava Ourotschevitch, Professor of University of Belgrade; M. Véllzar Jankovitch.

Besides the official delegates 700 unofficial delegates are attending the congress.

GLASGOW WAR RELIEF FUNDS.—A statement prepared by Mr. John S. Samuel, of the City Chambers, Glasgow, for the Lord Provost of that city shows that the amounts raised by various war relief funds from August, 1914, to December, 1916, total £2,550,199, or approximately £2 6*s.* per head of the population, a praiseworthy record.

WAR HOSPITALS IN THE EAST.—The officers' hospital in Busra has accommodation for about 50 officers, and is set apart for the nursing of acute cases only. The convalescent hospital at Beit Naama can take twice the number, and now possesses a launch, which every morning takes patients down from the hospital. Two of the Indian hospitals have an overflow barge-ward, which is much appreciated. Several English nursing sisters are now working in the Indian general hospitals.

The Indian Red Cross.—A branch of the Red Cross Society in Bombay has undertaken the important work of verifying the official reports of missing men by systematic inquiries covering the whole journey from the fighting line to the base depôts and hospitals, and from there to the invalid and convalescent camps in India.

OBITUARY OF THE WAR.

MICHAEL JOSEPH WHITTY, M.D., M.CH. R.U.I.,

LIEUTENANT-COLONEL, ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel M. J. Whitty, who died a month ago at Liverpool, was 54 years of age. He studied at Queen's College, Cork, and the Catholic University, Dublin, obtaining his qualification in 1884. Two years later he joined the Royal Army Medical Corps, retiring in 1906 after 20 years' service, when he was enrolled in the Reserve of Officers. At the outbreak of war he was appointed medical inspector of recruits for the Western Command, and was mentioned in a recent *Gazette* for his strenuous work in this capacity. In Liverpool, where he lived for many years, he was known as a kind and genial man and an up-to-date medical officer.

WILLIAM BROWN CLARK, M.B., B.S. LOND.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain W. B. Clark, who was recently killed in action in France, was younger son of Dr. G. B. Clark, ex-M.P. for Caithness-shire and Consul-General of the South African Republic. Educated at Lynton House and King's College Schools, he continued his medical studies at King's College Hospital, qualifying in 1903, when he obtained a house appointment at his hospital. He graduated M.B., B.S. Lond. two years later, going abroad to study neurology under Professor Edinger, at Frankfort. While there he contributed some articles on the origin of the cerebellum in animals to the *Journal of Anatomy and Physiology*. In 1907 he took charge of the Neurological Laboratory in King's College, carrying on experiments for Sir David Ferrier. It was his habit to practise during the winter at Villars (Switzerland) and Varenna (Italy), spending his summers in this country. When the war began he joined the Wounded Allies Relief Committee, proceeding to Antwerp, which place he left by the last steamer before its capitulation. He then went to Ostend and his report to the committee on the terrible condition of the Belgian wounded in that place was brought to the notice of the British Government, with the result that Captain Clark and his brother-in-law, Major W. A. Brend, filled the first transport of Belgian wounded at Ostend and brought it over to Dover. The difficulties of this task were graphically described by Major Brend in the *Nineteenth Century* of January, 1915.

Captain Clark joined the Royal Army Medical Corps in September, 1914, and held various appointments in hospitals, field and motor ambulances. At the time he was killed he was attached to a battalion of the Scots Guards. His chief wrote that though only a few months with the division, his sterling qualities and capabilities had proved a valuable asset to its medical staff. In 1906 Captain Clark married Ethel Vera, daughter of D. C. Howat, of Glasgow, and leaves a little daughter.

THOMAS GEORGE SMITH HODSON, M.D. DURH.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain T. G. S. Hodson, who lost his life by the sinking of the hospital ship *Salta* on April 10th, at the age of 53, was a son of the late William Hodson, of Downhills, Middlesex. Educated privately, he studied medicine at the London Hospital, taking his M.B. Durh. in 1893, and his doctorate five years later. He then practised for a time at Buxton and Bitterne (Hants), where he held several public appointments before settling in London. In June, 1915, he joined the Royal Army Medical Corps and was for some time attached to the Royal Victoria Hospital, Netley, afterwards serving on the Recruiting Medical Board at Bristol. Returning to Netley, he answered the call for volunteers for transport work, and was attached to the *Carisbrooke Castle*. In April he was appointed to the *Salta*, on which he had only been four days when the vessel was sunk in the Channel. A medical friend, who knew Captain Hodson for 20 years, writes that he never heard him speak a harsh word of anyone. Captain Hodson married in 1906 Margaret Mary, daughter of the late Dr. Samuel Hyde, of Buxton, and leaves two daughters and one son.

HARRY GRAHAM SMITH, L.R.C.S. EDIN., L.D.S.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain H. G. Smith, who lost his life by the sinking of the hospital ship *Salta* in the English Channel on April 10th, was a son of the late Dr. John Smith, F.R.S.E., a former President of the Royal College of Surgeons, Edinburgh. He was educated at Edinburgh Academy, obtaining his surgical qualification in 1883 and his dental three years later. He settled at Yealand Conyers, near Carnforth, where he became well known in the district. Always fond of a sea life, at the outbreak of the war he volunteered as surgeon on a transport, receiving a commission in August, 1915, when, after a few months on Salisbury Plain, he was appointed to the *Salta*. Captain Smith was a keen sportsman, shot, and angler, and loved an outdoor life. A medical friend writes of him as the best of companions and one who, owing to a wide experience gained by travelling in other countries, could give sound advice on many subjects.

M. R. HUGHES, M.B., B.S. MELB.,

CAPTAIN, AUSTRALIAN ARMY MEDICAL CORPS.

Captain M. R. Hughes, who was killed in France on March 20th last, was 25 years of age. He matriculated from Wesley College, Melbourne, entering Queen's College at the Melbourne University, where he graduated in medicine and surgery with honours in 1915, and qualified for appointment as one of the resident medical staff of the Melbourne Hospital. At the completion of his term at this hospital he joined the Australian Imperial Force. After his arrival in England he was transferred to France as

medical officer to an Australian infantry battalion, and was serving in this capacity when he was killed. His death will be deeply regretted by a large circle of friends amongst the younger members of the profession in Victoria.

BENJAMIN DIGBY GIBSON, L., L.M., D.P.H. R.C.P.S. I.,

CAPTAIN, AUSTRALIAN ARMY MEDICAL CORPS.

Captain B. D. Gibson, who died in Egypt on Jan. 14th whilst serving with the Anzac Mounted Division, was the only son of the late Henry Fisher Gibson, Deputy Registrar of the King's Bench, Dublin. He took his licentiateship in 1904 at the Royal Colleges of Surgeons and Physicians, Ireland, obtaining his Diploma in Public Health a few years later. He held various appointments, including that of house surgeon at the Royal City of Dublin Hospital and of resident medical officer at the Westmorland Hospital. Later he was assistant medical officer at the General Post Office and anæsthetist to the Dental Institute.

In 1914 he was in practice in the neighbourhood of Sydney, N.S.W., and on outbreak of hostilities was appointed to the Australian Army Medical Corps for home service, also acting as lecturer for the British Red Cross. A year later he was attached to a Light Horse Field Ambulance and was mentioned in the Katia-Romani despatch. He was subsequently transferred to another Light Horse Brigade and was recommended for honour by his commanding officer.

Captain Gibson was a freeman of Dublin and an active member of the Dublin Bay Sailing Club. He was unmarried.

GEOFFREY RATCLIFFE PLAISTER, M.R.C.S. ENG.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain G. R. Plaister, who was killed in action on April 11th at the age of 35, was younger son of Dr. W. H. Plaister, of Tottenham. He was educated at the London Hospital, taking his Conjoint qualification in 1905, when he settled in practice at Tottenham, becoming joint secretary to the North-East London Clinical Society. When war broke out he served at first as chief inspector to the local special constabulary, then obtaining a commission and becoming attached as medical officer to the Yorks and Lancaster Regiment. After being for some time the only officer in the regiment to come through unscathed he was killed almost instantaneously by a machine-gun bullet.

In an appreciation from the Tottenham Medical Union, Captain Plaister is described as a gentle and large-hearted personality, whose unassuming exterior concealed much worldly and medical wisdom. The union was formed on his suggestion to link the medical practitioners of the district in fraternal bonds. He will be specially missed by the poor of Tottenham, to whom he was a true friend.

JOSEPH NAYLOR, M.R.C.S. ENG.,

LIEUTENANT, ROYAL ARMY MEDICAL CORPS.

Lieutenant Naylor, who was one of the medical staff on H.M.H.S. *Salta*, and reported missing, supposed drowned when the vessel was mined in the Channel on April 10th, was the son of the late Mr. Joseph Naylor, J.P., sometime mayor of Kidderminster. He took his medical course at St. Bartholomew's Hospital, qualifying in 1889, and after holding an appointment as house surgeon at the Derbyshire General Dispensary he settled in practice at Tipton (Staffs), where he remained for 22 years.

In October, 1916, he volunteered for service at home or abroad, and after a period at Sunderland he was given embarkation and hospital-train duty. He was appointed to H.M.H.S. *Asturias*, and afterwards to the *Salta*.

THE UNITED STATES AND MEDICAL ORGANISATION FOR THE WAR.

The Supply of Medical Men and their Equipment.—The Medical Board of the Council of National Defence suggests the earlier graduation of senior classes in the medical schools of the country, the holding of continuous sessions, and the elimination of the year's hospital service heretofore required before entrance into the Navy or Army. The standardisation of all surgical instruments is advocated to ensure the exclusive production of the instruments needed by the combatant services and the elimination of all unessential types of instruments. Comparing these suggestions with the problem of keeping up the supply of medical men as presented to the authorities in England, the *Journal of the American Medical Association* says :—

> A medical school is, in a sense, a factory, the output of which is absolutely essential to the maintenance of the armed forces in the field. ..... The problem with us is quite clear. Medical schools and civil hospitals must be kept in operation. ..... The national emergency demands that they coöperate in overcoming the present grave shortage of medical men. This can be accomplished by reducing the teaching staff to a minimum, working through vacations to increase the product, or by the Italian plan, which meets the needs both of the service and the future at the same time.

The Italian plan, it is explained, is to send clinical faculties with attached medical students to base hospitals at the front, where army service is performed by caring for the sick and wounded, while instruction is continued at the same time. Men are thus graduated automatically into the medical corps of the Army during the progress of the war. Certain medical schools in America are already organising on these lines.

In the State of New York one thousand health officers are reported ready to make a preliminary examination of recruits. A mobile laboratory unit has also been organised to provide a diagnostic service at any point where needed for the mobilisation of the troops. The New York State Department of Health has ordered large supplies of vaccines, and a drinking water outfit is being worked out to provide calcium hypochlorite in sufficient quantity to disinfect 50 gallons of water, with means for removing the taste due to excess of chlorine.

Women Doctors and National Service.—In the *New York Medical Record* Dr. Mary S. Macy discusses the available means of organisation for national service among medical women in the United States. Of the estimated 145,240 persons qualified to practise medicine in the United States probably 5518, or nearly 4 per cent., are medical women. They are most strongly represented in the special departments, gynæcology claiming 519, obstetrics 143, pædiatrics 129, and ophthalmology (alone, or with ear, nose, and throat)

125. A large proportion are skilled in subjects which may be said to embrace the laboratory and social service fields of medicine (Dr. Macy computes it at 34 per cent.); they are versed in clinical pathology, roentgenology, public health, or bacteriology, which should make them specially useful if required for active service at the front. The remaining medical women, numbering 4500 or more, should, she thinks, be able to carry on the civilian medical work in their own communities, releasing men better equipped than themselves for military service.

Treatment of Tuberculous Soldiers.—Dr. Hermann M. Biggs, chairman of the Commission appointed by the National Association for the Study and Prevention of Tuberculosis, will have associated with him as members Dr. George M. Kober and Dr. Charles J. Hatfield. The chief work of this Commission will be directed towards the detection of incipient cases among the recruits in the Navy and Army and the prevention of the development and spread of the disease in the military forces and in the internment camps.

The Shortage of Salvarsan.—The Council of the St. Louis Medical Society have passed a resolution urging the Government to take prompt action "in view of the fact that an efficient arsenic product would be available in the market were it not for the present dangerous and unwarranted patent laws in regard to this and similar therapeutic products."

BLINDED SAILORS AND SOLDIERS.

Newington House Scheme.—At a recent conference at St. Dunstan's Hostel for Blinded Soldiers it was agreed that Newington House Hostel, Edinburgh, should be affiliated with St. Dunstan's while retaining control of its own affairs. All blinded Scottish sailors and soldiers who reside, or intend to reside, in Scotland will receive their training at Newington House. The official register of sailors and soldiers who have been blinded in the war will be kept at St. Dunstan's, and all recommendations with regard to additional allowances, bonuses, and other benefits will be received by the Pensions Ministry from St. Dunstan's only, but the authorities at Newington House will have a copy of this register, in so far as it relates to Scottish soldiers, submitted to them periodically.

Bazaar in Aid of St. Dunstan's Hostel.—On May 7th Queen Alexandra, who opened at the Albert Hall a bazaar organised in the interest of the work carried on at St. Dunstan's Hostel, thanked Sir Arthur Pearson for the work that he had done on behalf of the blind, adding that "nobody else could have accomplished it." Sir Arthur Pearson expressed the hope that the system of after-care which the bazaar was designed to benefit would smooth away the difficulties besetting the blind home-worker by providing him with raw material, supervising his work, marketing his goods, and assisting him in every way to overcome the handicap entailed by loss of sight. On succeeding days the bazaar was opened by Mrs. Lloyd George and the Lord Mayor of London.

RED CROSS THANKSGIVING.—On Thursday, May 17th, Ascension Day, the 3 o'clock service at Westminster Abbey will be devoted to thanksgiving for the beneficent work of the Red Cross. Application for tickets and all inquiries should be made to Mr. E. P. Vaughan-Morgan, Room 24, 83, Pall Mall, S.W.1. The north transept and nave of the Abbey will be open to the general public without tickets.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

To be temporary Surgeons: E. S. Bowes, S. S. Barton, J. S. McGrath, and D. S. Stevenson.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. H. W. Grattan to be temporary Colonel whilst employed as Assistant Director of Medical Services of a Division.

Lieut.-Col. Thomas H. J. C. Goodwin, C.M.G., D.S.O., to retain the acting rank of Colonel whilst employed as an Assistant Director of Medical Services at the War Office.

To be acting Lieutenant-Colonels: Temp. Capt. J. G. Johnston whilst commanding a Field Ambulance, Major N. Low, D.S.O., whilst commanding a Casualty Clearing Station.

Major A. W. Mayo Robson, C.V.O., C.B., R.A.M.C. (T.F.), to be temporary Lieutenant-Colonel.

The undermentioned are granted temporary rank whilst employed at the Sunderland War Hospital: As Lieutenant-Colonel: Lieut.-Col. J. W. Alexander, D.S.O., West Yorkshire Regiment (T.F.). As Majors: T. C. Squance, W. Robinson. As Captain: W. H. Maling.

To be temporary Majors: J. J. G. Blandford, Temp. Capt. L. B. Robertson, Canadian A.M.C., and Temp. Capt. J. F. Burgess, Canadian A.M.C.

Capt. C. W. Bowle relinquishes the acting rank of Lieutenant-Colonel on re-posting.

Temporary Lieutenants to be temporary Captains: R. L. Bell, W. R. H. Smith, G. A. Back, W. V. Pegler, H. W. Evans, H. Hendry, H. E. Whtttingham, J. Nunan, J. W. Tonks, L. R. F. P. Marshall, J. A. Fretton, G. E. Dodson, G. G. Old, H. Mohan, S. Macnaughton, S. C. W. Iredale, G. B. King, J. F. Nicholson, I. O'Keffe, D. Morrison, T. R. Hunter, W. Halliwell, J. A. H. Telfer, F. J. H. Begg, F. L. Keith, T. P. Hutchison, T. B. Brandon, V. Wallace, C. J. McCarthy, J. T. Blessdell, J. A. C. Roy, E. J. Dyke, H. B. Maxwell, S. Littlewood, W. B. Anderson, D. Ross, S. Robson, R. T. Taylor, A. E. Pinniger, W. Ward-Smith, J. P. Lowson, J. McF. Donnan, P. Milnes, R. A. Leembruggen, J. F. C. O'Meara, C. G. Skinner, A. M. Bayne, C. B. A. Frow, G. Stewart, L. B. W. Braine, E. C. A. Reynolds, R. A. McKay, J. E. O'Donnell, H. G. Joyce, J. C. Houston, C. W. Aikman, J. G. Ackland, W. R. White-Cooper, A. T. Edwards, A. C. Pickett, J. H. Lechler, F. E. Fellden, V. J. P. Clifford, W. S. Allan, W. H. W. C. Carden, S. H. L. Archer, C. Dundee, S. Pool, A. Beeley, A. H. Smith, C. Cameron, E. Hudson, A. A. Hill, A. D. Millington, J. V. Watson, A. C. Price, D. A. Chalmers, F. F. Carr-Harris, E. A. T. Green, L. L. McKeever, J. D. Wright, H. C. Davies, A. Ball, W. G. Shaw, G. J. McGorty, E. H. Shaw, L. Walton, T. D. Miller, R. C. B. Briscoe, F. R. Wilson, P. A. Rostant, J. Dickson, C. Harris, R. J. Arundel, J. P. Pegum, J. F. Penman, D. Corry, A. Wilson, A. Sunderland, K. M. Walker, J. F. Blackett, A. E. Gravelle, J. B. Wood, and G. E. Kinnersly.

Temp. Hon. Lieut. D. H. D. Cran to be temporary honorary Captain whilst serving with the Scottish Red Cross Society, and W. Martin to be temporary Honorary Captain while employed with the British Red Cross Hospital, Netley.

F. Packard to be temporary Honorary Lieutenant whilst serving with a General Hospital.

Officers relinquishing their commissions: Temp. Lieut.-Col. A. H. Burgess (Major, R.A.M.C., T.F.), having resigned his appointment; Temp. Lieut.-Col. F. D. Bird, C.B.; Temp. Capts. L. A. Walker, W. N. Rishworth, E. J. Eedle, F. L. Gill, W. T. Smith, W. A. Kennedy, H. R. Brown, J. L. Digby, C. Farrondge, W. P. Noall, J. N. Glaister, J. J. Crawford, A. H. Corley, A. D. Howard, R. Williams, C. A. Robinson, C. Butler, W. B. Lawrence, A. R. Rendle, W. J. Hill, J. W. Heekes, J. M. Twentyman, H. H. Clarke, H. M. Meyrick-Jones, A. P. Yonge, W. A. H. Birrell, D. T. Fraser, R. F. Jones (on account of ill-health), W. W. Scott, J. F. Steven, D.S.O. (on account of ill-health); Temp. Lieuts. J. E. Middlemiss (on account of ill-health), J. C. Buckley, D. R. Taylor, A. Whittome, E. Slack, H. B. Thomson, D. A. Crow, H. A. Macdonald, C. M. Eadie, W. F. Cornwall, F. J. MacManus, R. A. Slater, R. S. Novis, W. H. Soady, R. C. Corbett, W. W. W. Watt, J. E. Harford, J. G. Ross, A. E. Harrison, H. L. Morrow, J. R. Hall, P. J. Murray, J. E. C. Maguire, D. J. Jackson, W. Patey, W. A. Steen, M. F. Taylor, A. F. Seacombe, A. H. Arnott, and H. C. Terry.

SPECIAL RESERVE OF OFFICERS.

Capt. R. Magill relinquishes the rank of acting Lieutenant-Colonel on re-posting.

F. G. L. Dawson (from University of London Contingent O.T.C.) and T. H. Rhys to be Lieutenants.

TERRITORIAL FORCE.

Major C. A. Lees to be acting Lieutenant-Colonel whilst holding the appointment of Administrator.

Capts. J. S. Manford and A. T. Mulhall to be acting Lieutenant-Colonel whilst commanding a Field Ambulance.

Capt. (temp. Major) T. H. Peyton to be acting Lieutenant-Colonel whilst commanding a Field Ambulance.

Capt. A. Rodger, from T.F. Res., to be Captain, with precedence as from August 14th, 1915.

Capt. T. W. Morcom-Harneis to be acting Major whilst in command of a Field Ambulance.

Capt. A. G. T. Fisher to take rank and precedence in the R.A.M.C., T.F., and in the Army as if his appointment as Captain bore date the 10th day of July, 1916.

Capt. (acting Lieut.-Col.) A. J. Evans relinquishes his acting rank on ceasing to command a Field Ambulance.

Surg.-Maj. F. W. Bailey, D.S.O., from R.F.A., to be Major, with precedence as from Dec. 12th, 1915.

To be Captain: Lieut. J. Rosencwige, Lieut. W. C. D. Maile.

A. W. W. Baker to be temporary Captain whilst serving with the O.T.C.

Major A. H. Burgess is restored to the establishment.

H. C. Sands to be Lieutenant.

Capt. (acting Major) T. H. Chittenden relinquishes his commission on account of ill-health, and is granted the honorary rank of Lieutenant-Colonel.

VOLUNTEER FORCE.

Suffolk Volunteer Regiment, 5th Battalion: A. Leeming (late Lieutenant, R.A.M.C.) to be temporary Captain.

INDIAN MEDICAL SERVICE.

Lieut.-Col. A. Miller to be Professor of Medical Jurisprudence, Medical College, Madras, in addition to his other duties.

The King has approved the promotion of the following officers:—

Majors to be Lieutenant-Colonels: C. A. Lane, T. B. Kelly, C. H. Watson, E. F. E. Baines, G. O. F. Sealy, J. G. P. Murray, Brevet Lieut.-Col. S. Anderson, F. H. G. Hutchinson, J. L. Marjoribanks, A. Fenton, R. W. Knox, D.S.O.

Captains to be Majors: A. F. Hamilton, A. D. White, A. A. McNeight, N. M. Wilson, J. S. O'Neill, W. S. Nealor.

Lieutenants to be Captains: G. H. Mahony, G. Covell, W. R. Stewart, Kotyvenkata Ramna Rao, J. G. O. Moses, Hari Chand, Venkatasubba Mahadevan, A. C. L. O'S. Bilderbeck, J. W. Van-Reenen, B. F. Beatson, M. J. Roche, N. Das Puri, Prabodh Chandra Roy, Monmdranath Das, Jagannath Balkrishna Vaidya, J. M. R. Hennessy, A. G. Cowper, W. M. Lupton, H. H. Brown, C. H. N. Baker.

The King has also approved the grant of the temporary rank of Lieutenant to Noormahomed Kasembhai Chohan, and the relinquishment of temporary Lieutenant by Kaikhusro Kersaspji Dadachnji.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Venereal Disease Bill.

THE Venereal Disease Bill has been passed by a Standing Committee of the House of Commons, but its form has been greatly altered.

On Thursday, May 3rd, the Committee resumed the consideration of Clause 1, which provides for the prevention of the treatment of venereal disease or the supply of remedies therefor otherwise than by duly qualified persons. The first subsection had been disposed of at the previous sitting.

Mr. GLYN-JONES moved as an amendment the insertion of a new subsection in the following terms:—

No qualified medical practitioner shall supply to any patient any remedy for the treatment of a venereal disease except in areas in which for the time being a medical practitioner is permitted to supply drugs or medicines to insured persons under the National Insurance Acts or in cases where the practitioner himself administers the remedy to the patient. Provided that nothing in this subsection shall interfere with the supply of remedies by any institution or hospital approved by the Local Government Board for the treatment of venereal disease to patients attending such institution or hospital.

The honourable Member said that the effect of the Bill as it stood would be that medical men would be protected, not only in their proper function of diagnosing and prescribing for venereal diseases, but they would be able to take over the dispensing of medicines as far as they desired. The medical man would require the pharmacist to send his (the pharmacist's) customers to him. The separate functions of the medical man and the pharmacist were recognised at the time when the Insurance Act was passed. All that he asked the Committee to say was that the doctor should do his proper work and receive his proper fee, and that the pharmacist should supply the drugs, not on his own initiative but because they were prescribed by a medical man.

Sir P. MAGNUS, in opposing the amendment, failed to see any valid reason for altering the law as it now existed regarding the legal right of members of the medical profession to supply drugs in certain cases. The honourable Member talked about interfering with the rights of the chemist in supplying medicines. The Bill did nothing of the sort. All that it interfered with was the right to supply medicines for these specific diseases without a prescription. If he got the prescription he could supply the remedy. The amendment proposed to take away from the medical practitioner a right now given him by law. But the Committee had to look at this question from the wider point of view of public health and not from the pecuniary point of view of any profession. The Committee had to remember that persons suffering from these diseases were anxious that the fact should be known to as few as possible. The medical man was under a moral obligation not to allow what had been communicated to him as a medical man to be known, and in order to maintain the relation of confidence he should not be prevented from supplying the medicine to the patient.

Mr. HAYES FISHER (Parliamentary Secretary to the Local Government Board) said that the honourable Member (Mr. Glyn-Jones) was inviting the Committee to enter on the old battle, that doctors only should prescribe and chemists only should dispense. He hoped that the Committee would not be led aside by that. Medical men now had the power to dispense, and if the amendment was adopted it would be taken away from them so far as venereal diseases were concerned. He did not think that the Committee should do anything by this Bill to take that right away. He thought that medical men and chemists were both going to lose pecuniarily by the Bill and by the new policy of which it was a part, but the community would benefit. As the clinics for free treatment, of which the State bore 75 per cent. of the expenditure came into existence, and as people resorted to them, medical men would lose part of their private work. Chemists would lose something also, but he thought the medical men might lose more than the chemists. Just as the Sabbath was made for man and not man for the Sabbath, so doctors and chemists were made for the community and not the community for doctors and chemists. He thought the Committee should reject the amendment.

After some discussion the amendment was rejected by 22 votes to 8.

The Committee then proceeded to rearrange and redraft the remaining clauses of the Bill.

A second subsection was added to Clause 1 in the following terms:—

This section shall operate in any area to which it is applied by order of the Local Government Board or in Scotland and Ireland the Local Government Board for Scotland and Ireland respectively. Provided that no order shall be made in respect of any area until a scheme for the gratuitous treatment of persons in that area suffering from venereal disease has been approved by the Local Government Board or, in Scotland and Ireland, the Local Government Board for Scotland and Ireland respectively, and is already in operation.

Emphasis was placed by several members of the Committee on the desirability of having gratuitous treatment in operation before an order was made in regard to any area.

The other subsections of Clause 1 were cut out and the clause as amended was agreed to.

On the motion of Mr. GLYN-JONES, the following new clause was inserted in the Bill:—

A person shall not by any advertisement or any public notice or announcement offer to treat any person for venereal disease, or to prescribe any remedy therefor, or to give any advice in connexion with the treatment thereof.

A person shall not hold out or recommend to the public by any public notice or advertisement, or by any written or printed papers or handbills, or by any label or words written or printed affixed to or delivered with any packet, box, bottle, phial, or other enclosure containing the same, any pills, capsules, powders, lozenges, tinctures, potions, cordials, electuaries, plaisters, unguents, salves, ointments, drops, lotions, oils, spirits, medicated herbs and waters, chemical and officinal preparations, whatsoever to be used or applied externally or internally as medicines or medicaments for the prevention, cure, or relief of any venereal disease.

Provided that nothing in this section shall apply to any advertisement, notification, announcement, recommendation, or holding out made or published with the sanction of the Local Government Board, or to any publication sent only to duly qualified practitioners and/or to wholesale or retail chemists for the purposes of their business.

Another new clause was inserted in the Bill reproducing the terms of Subsection 3 of Clause I. of the original Bill in the following terms:—

If any person acts in contravention of any of the provisions of this Act he shall be liable on conviction on indictment to imprisonment, with or without hard labour, for a term not exceeding two years, or on summary conviction to a fine not exceeding one hundred pounds, or to imprisonment with or without hard labour for a term not exceeding six months.

A definition clause was agreed to as follows:—

In this Act the expression "venereal disease" means syphilis, gonorrhœa, or soft chancre.

The Bill as amended was ordered to be reported to the House.

Highlands and Islands Medical Service Board.

The report of this Board for the year 1916, now presented to Parliament and issued as a White Paper, shows that owing to war conditions the Board have not been able to give full effect to their various intentions. The needs of some of the more necessitous districts have been met as far as circumstances permitted, but in many districts no progress has been possible. The rest of the Board's schemes, and particularly those providing for capital expenditure, are practically in abeyance for the period of the war. The greater part of the work for which the Board was called into existence still remains to be done. Considerable progress has been made with the introduction of a medical service at modified fees to certain classes of the community, but the scheme is still incomplete, and the Board have not yet had sufficient experience of its working to enable them to determine whether, and, if so, to what extent, it may call for modification. For the present it applies to the crofter and cottar classes and their families and dependents, and others in like circumstances, to whom the payment of the practitioner's ordinary fee for medical attendance would be an undue burden. The fees chargeable to such persons will not exceed 5*s.* for the first visit and 2*s.* 6*d.* for each subsequent visit in the same illness. The maximum fee in midwifery cases has been fixed at £1. The estimated expenditure under the scheme for 1916, £20,000, has been exceeded by £500. The estimate for 1917 has been fixed at £22,000. A beginning only has been made with the organisation of nursing, but reference is made to the question of efficient nursing in connexion with maternity and child welfare schemes which, together with the Notification of Births (Extension) Act, 1915, and the Midwives (Scotland) Act, 1915, make necessary a unification of the nursing service if overlapping is to be avoided and economy in administration secured. The policy of the Board with regard to nursing in large areas is exemplified in the arrangements made for the Island of Lewis, the district committee being charged with the administration of both the last-mentioned Acts, while they also undertake the management of the general nursing service. It is provided that district nurses subsidised by the Board will be in the employment of the district committee, and their appointment and dismissal will be in the hands of the committee, subject to the approval of the Board. The report concludes with an expression of indebtedness to the Education Department of the Local Government Board for Scotland for permitting their officers to take part in the work of organising the Board's schemes, and to the Naval authorities for their kindness in arranging for the conveyance of doctors, nurses, and medical stores to and from outlying islands where the ordinary means of communication are at present in abeyance.

Billeting of Civilians and Infectious Disease.

As the result of representations during debates in the House of Commons on the Billeting of Civilians Bill a clause was introduced into the Bill to permit occupiers of premises in which persons were billeted under the measure to receive compensation for the loss or damage caused by the introduction of infectious disease.

HOUSE OF COMMONS.

WEDNESDAY, MAY 2ND.

Medical Classification in the Army.

Answering Mr. HOGGE, Mr. MACPHERSON (Under Secretary for War) said: It is not necessarily the existence of a disability but the degree of disability which determines a man's classification. Thus, varicose veins, if exceptionally severe, might lead to a man being rejected; if less severe, to his being placed in category C 3 or C 2, and so on. Their mere existence would not debar a man from being placed in category A. This might be quite unimportant. Each case must be judged by the medical man before whom the case comes on its own merits.

Medical Re-examinations.

Mr. G. LAMBERT asked the Under Secretary for War whether a man medically discharged from the Army and called up again under the recent Act had the right of appeal from the decision of the Army medical authorities.—Mr. MACPHERSON replied: A man called up and examined by a recruiting medical board under the Military Service (Review of Exceptions) Act, 1917, has no right of appeal against his medical classification by the board. Each man, however, to whom the notice requiring him to be medically examined is sent under the Act, has the right of application to a tribunal within 30 days from the sending of the notice for exemption from military service on any grounds set out in the Military Service Act, 1916, Section 2 (1), including the ground of ill-health or infirmity.

Mr. LAMBERT: Would a certificate from a man's own medical adviser be accepted?—Mr. MACPHERSON: I said in the course of the debate on the Act that due regard would be given to any certificate from a family practitioner.

Malarial Cases in the Army.

Mr. COWAN asked the Under Secretary for War whether the cases of malaria among officers and rank and file, now in England, were being generally treated by medical practitioners without special experience of that disease, which had resulted in a loss of man power to the Army by the prolongation of the treatment; and whether all malaria cases would now be put through a short but stringent course of treatment for the purpose of eradicating their infections immediately and allowing of their early return to duty.—Mr. MACPHERSON answered: Centres for the treatment of malaria have been established in each Command, and officers with experience of this disease have been placed in charge of them. Malarial cases are now being put through a course of treatment with the hope of eradicating the disease.

MONDAY, MAY 7TH.

Medical Men and Research Work.

Sir J. D. REES asked the Under Secretary for War whether, in calling up members of the medical profession, members whose research work was by common consent of public value would be included amongst the number of those who remained in the United Kingdom.—Mr. MACPHERSON replied: The decision as to the individuals to be called up has been delegated to the professional tribunals set up under the Military Service Act, and the point which my honourable friend has in mind will be for their consideration.

TUESDAY, MAY 8TH.

Medical Officers and Administrative Work.

Answering Major CHAPPLE, Mr. MACPHERSON (Under Secretary for War) said: The number of medical officers solely occupied with non-professional work in hospitals is negligible. The administrative duties are so bound up with professional knowledge and experience that no saving in medical officers would result from increasing the number of non-medical officers now employed.

Artificial Limbs.

In reply to Major CHAPPLE, who asked a question in regard to the supply of artificial limbs, Mr. BARNES (Minister of Pensions) said: To give satisfaction to the patient and to secure lasting qualities an artificial limb must be of the very best materials and workmanship and very carefully fitted to the person for whom it is made. I am advised that in these circumstances satisfactory limbs cannot be produced at so low a cost as £5, and I do not think that any advantage would be gained by bringing another department into the procedure of their supply.

Major CHAPPLE asked whether, in the case of a limbless officer, a sum of £25 is given him with which to buy an artificial limb; whether, in some cases at least, such an officer had had to pay £40; whether these limbs could be made for something over £5; and whether, in the interest of wounded soldiers as well as in the interest of economy, the right honourable gentleman intended to take any steps in the matter.—Mr. BARNES answered: It is not the case that a limbless officer is given a lump sum irrespective of the nature of the limb required. In Army Council Instruction No. 786 of 1916 a scale of prices is fixed for the various types of limb varying from £10 10*s.* for a Syme's amputation to £29 8*s.* for an ordinary leg with pelvic band and to £40 for an arm of a complex type for use in special cases, and the officer is given the price allowed by the scale for the type of limb required. No change is at present contemplated in this arrangement except such as may be occasioned by improvement of the type and by reduction in price due to competition.

Medical News.

A NEW wing of the Royal Naval Hospital at Haslar, the gift of the women of Canada, was formally opened by the Queen on Wednesday. Surgeon-General Sir A. W. May, Director-General of the Naval Medical Service, stated that £40,000 had been raised for the purpose, the hospital extension having taken the place of the hospital ship at first suggested, in order to give permanent expression to the Canadian women's generous gift.

MORTALITY AMONGST WOMEN IN CALCUTTA.—The excessive mortality amongst women and children in Calcutta is the subject of strong comment in the departmental report of the municipal health officer. The death-rate is 50 per cent. higher amongst women than amongst men, an evil, as the health officer points out, largely due to the observance of the purdah system in insanitary environments. This system, he suggests, would probably not be productive of much harm in garden houses with spacious compounds, but in the slums of a city it is fatal, involving the constant exposure of the women to insanitary surroundings, and creating grossly insanitary conditions. In a congested city it is difficult to secure privacy without sacrificing fresh air, the zenana is in consequence situated at the back of the house and inadequately lighted and ventilated. While the man who resides amid insanitary surroundings is usually away from home for the greater part of the day there is no such escape for the purdah woman. The terrible results are indicated by the fact that while the actual male death-rate in 1915 was 24·1 per 1000, the female rate was 37·8 per 1000.

LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY, LIMITED.—The annual meeting of this society will be held on Wednesday next, May 16th, at 32, Craven-street, Strand, W.C. 2, at 4 P.M., when the annual report for the year 1916 will be presented. The report gives the gratifying information that the work for the year has been little affected by the war. The membership of the society has remained almost stationary, decrease in one class of cases being counterbalanced by increase in another. The income and expenditure account shows a balance carried forward of £1783 18*s.*

HOSPITAL AND HOME FOR SICK CHILDREN, LOWER SYDENHAM.—The annual report and statement of accounts for the year 1916 shows that this institution has suffered financially owing to the war. Largely owing to the increased cost of food a debt of £800 by way of loan has been incurred, to meet which stock must be realised at great sacrifice. The in-patient cases admitted during the year were 316, the out-patient attendances 3864 and the casualty cases 2411. Much good work was done in the eye and throat department, where children sent in by the London County Council are treated.

ASYLUM WORKERS' ASSOCIATION.—The annual general meeting of this association will be held at the Mansion House, London, on Monday next, May 14th, at 3 P.M., when the Lord Mayor, vice-president, will preside. The following, amongst others, are expected to take part in the proceedings: Sir John Jardine, President; Dr. David Nicolson, Sir William J. Collins, Sir James Crichton-Browne, Hon. Major Sir Robert Armstrong-Jones, Sir George H. Savage, Sir Frederick Needham, Dr. C. Hubert Bond, and Lieutenant-Colonel Thomson.

ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN.—At the annual meeting held on April 25th it was stated that while the price of food, coal, light, and medical dressings required in the hospital had gone up, the expenditure on the whole had gone down. The total surgical and medical attendances for the year numbered 26,842. On the medical side the work had been carried out by Dr. A. S. Cumming, Dr. R. Thin, and Dr. C. Mowbray Pearson. In the absence from the hospital on war duty of Mr. Stiles and Mr. Fraser, Mr. A. P. Mitchell had been in full charge of all surgical work.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

COLLIE, Sir JOHN, M.D., has been appointed a Physician to the Hospital for Epilepsy and Paralysis and other Diseases of the Nervous System, Maida Vale, W.

COMYN, HAROLD F., M.B., B.C.Cantab., M.R.C.S., L.R.C.P. Lond., Officer in Charge of Tuberculosis Department, Great Northern Central Hospital.

FORTY, DANIEL HERBERT, L.R.C.P. Lond., M.R.C.S., Medical Officer and Public Vaccinator for the Charfield District of the Thornbury (Gloucestershire) Union.

HANCOCK, J. B., M.R.C.S., L.R.C.P. Lond., Certifying Surgeon under the Factory and Workshop Acts for the Robertsbridge District of the County of Sussex.

MACKEOWN, W. J., M.B., B.S. R.U.I., Certifying Surgeon under the Factory and Workshop Acts for the Bishop's Waltham District of the County of Hants.

MEADEN, CHARLES, M.D., B.S. Durh., Acting Medical Officer for the Braunton District of the Barnstaple (Devon) Union.

RIVERS, CHARLES HENRY, Medical Officer of Health for the Redruth (Cornwall) Rural District.

TRAILL, A., Acting District Medical Officer for the Barnstaple (Devon) Board of Guardians.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).
When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

APPLECROSS, Ross-shire.—Medical Officer and Public Vaccinator. Salary £320 per annum.

BARNSLEY AND WAKEFIELD JOINT SANATORIUM COMMITTEE.—Resident Assistant Tuberculosis Officer and Resident Medical Officer at Mount Vernon Sanatorium. Salary £300 per annum, with board, &c.

BIRMINGHAM GENERAL DISPENSARY.—Resident Medical Officer, unmarried. Salary £300 per annum, with apartments, &c.

BOLINGBROKE HOSPITAL, Wandsworth Common, S.W.—House Surgeon. Salary £150 per annum, with board, &c.

BOLTON INFIRMARY AND DISPENSARY.—Second House Surgeon. Salary £200 per annum, with board, &c.

BRISTOL ROYAL INFIRMARY.—House Physician and House Surgeon. Salary at rate of £120 per annum, with board, &c.

BURNLEY, VICTORIA HOSPITAL.—House Surgeon. Salary £160 per annum, with board, &c.

BURSLEM, HAYWOOD HOSPITAL.—Female Resident Medical Officer. Salary £200 per annum, with board, &c.

CARDIFF, KING EDWARD VII.'s HOSPITAL.—House Surgeon for six months. Salary at rate of £175 per annum, with board, &c.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.—House Surgeon. Salary £200 per annum, with board, &c.

DERBY, DERBYSHIRE ROYAL INFIRMARY.—Two House Surgeons. Salary £200 per annum, with board, &c.

DERBYSHIRE COUNTY COUNCIL.—Temporary Medical Superintendent for County Sanatorium and Tuberculosis Officer. Salary £500 per annum.

DEVONPORT, ROYAL ALBERT HOSPITAL.—House Surgeon, unmarried. Salary £150 per annum, with board, &c.

EVELINA HOSPITAL FOR CHILDREN, Southwark, S.E.—House Physician for four months. Salary at rate of £160 per annum, with board, &c.

GLOUCESTERSHIRE ROYAL INFIRMARY AND EYE INSTITUTION.—Senior House Surgeon. Salary £150 per annum, with board, &c.

HOLLAND (LINCOLNSHIRE) COUNTY COUNCIL.—Temporary County Medical Officer of Health and Temporary School Medical Officer. Salary £450 per annum.

HULL, VICTORIA HOSPITAL FOR SICK CHILDREN.—House Surgeon.

IPSWICH, EAST SUFFOLK AND IPSWICH HOSPITAL.—Two Female Resident Officers.

ITALIAN HOSPITAL, Queen-square, London, W.C. 1.—House Surgeon for six months. Salary £80 per annum, with board, &c.

KENSINGTON BOARD OF GUARDIANS.—Resident Assistant Medical Officer Locum Tenens for Marloes-road Institution. Salary 7 guineas per week, with board, &c.

LEEDS PUBLIC DISPENSARY.—Resident Medical Officer. Salary £200 per annum, with board, &c.

LINCOLN, CITY OF.—Temporary Assistant Medical Officer of Health. Salary at rate of £300 per annum.

MANCHESTER, HULME DISPENSARY, Dale-street, Stretford-road.—House Surgeon. Salary £250 per annum, with apartments, &c.

NOTTINGHAM CHILDREN'S HOSPITAL.—Female House Surgeon. Salary at rate of £200 per annum, with board, &c.

PAISLEY PAROCHIAL HOSPITAL, LUNATIC WARDS, AND POORHOUSE, Craw-road.—Resident House Surgeon. Salary £260 per annum, with board, &c.

PLAISTOW FEVER HOSPITAL, London, E.—Temporary Female Resident Medical Officer. Salary at rate of £300 per annum, all found.

QUEEN MARY'S HOSPITAL FOR THE EAST END, Stratford.—Casualty Officer.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Election of Professors and Lecturers.

ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Senior Resident Medical Officer. Salary £200 per annum. Also House Physician. Salary £50 per annum, with board, &c.

ST. GEORGE'S HOSPITAL, S.W. 1.—Temporary Assistant Surgeon for six months.

ST. HELENS COUNTY BOROUGH.—Temporary Assistant Medical Officer of Health. Salary £350 per annum.

ST. PETER'S HOSPITAL FOR STONE, &c., Henrietta-street, Covent Garden, W.C.—Senior and Junior House Surgeons for six months. Salaries at rate of £75 per annum, with board, &c.

SHEFFIELD ROYAL INFIRMARY.—House Physician. Salary £120 per annum, with board, &c.

SURREY EDUCATION COMMITTEE.—Temporary School Dentist. Salary £300 per annum.

UNIVERSITY COLLEGE HOSPITAL.—Casualty Surgical Officer. Salary £100 per annum, with lunch. Also Assistant in Dermatological Department and Part-time Assistant in Venereal Diseases Department. Salary £200 per annum, with lunch.

WARWICKSHIRE AND COVENTRY JOINT COMMITTEE FOR TUBERCULOSIS.—Temporary Tuberculosis Officer. Salary £500 per annum.

WELLS ASYLUM, Somerset.—Temporary Assistant Medical Officer. Salary £300 per annum, with board, &c.

WORCESTERSHIRE, KING EDWARD VII. MEMORIAL SANATORIUM, Knightwick, near Worcester.—Temporary Medical Superintendent and Tuberculosis Officer. Salary £450 per annum, with board, &c.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Grosmont (Yorks) and at Tipton (Stafford).

Births, Marriages, and Deaths.

BIRTHS.

BATTY SHAW.—On May 6th, Muriel, wife of Dr. Batty Shaw, F.R.C.P., of a daughter.

BELL.—On May 1st, at Knaresborough-place, S.W., the wife of Major F. C. Bell, C.A.M.C., of a son.

HILTON.—On May 6th, at The Corner House, Northwood, the wife of O. Hilton, M.D., of a daughter.

MAWHOOD.—On May 4th, at Chalcots, Ascot, the wife of R. H. Mawhood, M.B., B.C. Cantab., F.R.C.S. Eng., of a son.

VERCOE.—On April 29th, at Old Court, Ealing, the wife of Richard H. Vercoe, M.R.C.S., L.R.C.P., of Southall, of a daughter.

MARRIAGES.

CROSS—WEAVER.—On April 23rd, quietly, in London, Leopold Harold Cross, L.D.S. Eng., Captain, R.A.M.C., to Clarice Blanche, daughter of the late John Weaver and Mrs. Weaver, of Streatham.

DRAKE-BROCKMAN—PILKINGTON.—On May 7th, at St. Botolph's Church, West Worthing, Lieutenant-Colonel Ralph H. Drake-Brockman, R.A.M.C., to Helen Maud, second daughter of Major Sir H. Pilkington, K.C.B., R.E. (retired), and Lady Pilkington, of Studland House, Worthing.

GRAY—COOPER.—On April 26th, at St. John's, Red Lion-square, Archibald Montague Henry Gray, M.D., Major, R.A.M.C., T.F., of 30, New Cavendish-street, W., only son of the late Dr. F. A. Gray, of Ottery St. Mary, Devon, to Elsie, youngest daughter of the late F. B. Cooper, of Newcastle, Staffs.

PICKLES—TUNSTILL.—On May 5th, at St. Andrew's Church, Aysgarth, Yorkshire, by the Rev. W. K. Wyley, M.A., vicar of the parish, Surgeon William Norman Pickles, M.B., M.S. Lond., R.N.V.R., son of Dr. J. J. Pickles, of Leeds, to Gertrude Adelaide, daughter of Harry Tunstill, of Thornton Lodge, Aysgarth, and of Rivington, Pendleton, Manchester.

DEATHS.

ADENEY.—On May 2nd, at Haward Lodge, Tunbridge Wells, Edwin Leonard Adeney, M.D., J.P., aged 58 years.

COALBANK.—On Saturday, May 5th, at Teddington Lodge, Teddington, Isaac Coalbank, M.R.C.S. Eng., L.S.A., M.D. Paris, aged 73 years.

DOUDNEY.—On April 29th, at Kombe, Northern Nigeria, of malaria, Dr. Leslie Doudney, W.A.M.S., aged 38 years.

FOWKE.—On April 27th, at Byfield, Northamptonshire, Frederick William Fowke, M.R.C.S. Eng., M.R.C.P. Edin., L.S.A. Lond., aged 73 years.

FOX.—Missing, believed drowned, on April 15th, Lieutenant-Colonel A. C. Fox, D.S.O., R.A.M.C.

KERR.—On April 26th, in San Francisco, William Watt Kerr, M.D. Edin., aged 59 years.

LONES.—Killed in action, on April 28th, Captain Percy East Lones, R.A.M.C., aged 30 years.

NASON.—On April 29th, at "Arbury," Stratford-on-Avon, John James Nason, M.B., J.P., aged 84 years.

SQUIRE.—On May 2nd, at his residence, Bentinck-terrace, North-gate, Regent's Park, N.W., after three days' illness, John Edward Squire, C.B., M.D., F.R.C.P., aged 61 years.

SYMONS.—Killed in action, on April 30th, Lieutenant-Colonel (acting Colonel) Frank A. Symons, C.M.G., D.S.O., Assistant Director of Medical Service.

TACKABERRY.—On March 25th, at a Stationary Hospital abroad, Captain John Bailey Tackaberry, I.M.S., aged 34 years.

TURNER.—On May 2nd, at Clifton, George Browne Turner, M.D., J.P., of Camden House, Hemel Hempstead, in his 91st year.

WILLIAMS.—Died May 4th, 1917, at Gullsborough, Northants, Henry William Williams, M.D., aged 81, eldest son of the late William Williams, surgeon, of Gullsborough, Northants.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

THE following promotions and appointments to the Order of the Hospital of St. John of Jerusalem in England have been made: Major Sir Edward Scott Worthington, C.M.G., M.V.O., and Lieutenant-Colonel Frank Warburton Begbie, R.A.M.C., to be Knights of Grace, and Surgeon Lieutenant-Colonel James Stuart Brooke, V.D., to be an Esquire.

Notes, Short Comments, and Answers to Correspondents.

MICROSCOPIC STAINING WITH COPYING-INK PENCIL.

AT a recent meeting of the Zurich Medical Society, Dr. Louis E. Merian called attention to the convenience of using coloured pencils in staining microscopical preparations. The idea was suggested to him by a paper of Dr. E. Friedberger in the Military Supplement of the *Münch. med. Wochenschr.* of Nov. 21st last. Friedberger has invented a universal pencil for staining pus and blood films as well as gonococci, trypanosomes, spirochætes, and malaria parasites, and he proposes to bring out a Giemsa and a carbol-fuchsin pencil after the war. The method of staining suggested was very simple. After fixing, a drop or two of water was placed on the slide, and the coloured pencil rubbed in the water until the required depth of colour was attained. The preparation was then rinsed and dried in the usual way. It occurred to Dr. Merian that the ordinary indelible pencil obtainable for 1*d.* (they now cost 4*d.*) might serve the same purpose. The result proved satisfactory for white and red blood corpuscles, gonococci, and spirochætes. Of the various makes of indelible pencil obtainable in Switzerland Dr. Merian found "A. W. Faber Radium 5800" the most suitable, while Faber's "Castell," Hardmuth's "Mephisto 73 B. middle," and Rehbach's "Defregger" were also good. Dr. Merian claims a special handiness and cleanliness for this method as well as the convenience of carrying the pencil anywhere in the pocket. The stain keeps indefinitely and does not deteriorate as stains do in solution.

We have used this method in emergency, finding it to work well for pus, blood, and cultures. The drop of water should be placed by the side of the film, the indelible pencil rubbed well into it, and the coloured drop then led over the preparation.

THE SPARROW.

IT is officially explained that the sparrow whose destruction the Board of Agriculture urged is the house-sparrow, not the hedge-sparrow, "which is an eminently useful bird, to be encouraged by all possible means."

Some useful information with reference to this bird will be found in a small book published in 1899 by Vinton and Co., entitled "The House Sparrow: The Avian Rat," by William Bernhard Tegetmeier, F.Z.S., with an appendix by Eleanor A. Ormerod, F.E.S., of the University of Edinburgh. In his preface Mr. Tegetmeier said:—

> It is a remarkable fact that there is not one eminent, practical ornithologist of the present day in England or elsewhere who advocates the protection of this species. Many of those in the very first rank of science, and with the greatest experience of country life and knowledge of practical ornithology, who advocated the claims of this bird to protection in their youth, have, as the result of further experience and careful observation, been led to denounce it.

The tree-sparrow (*Passer montanus*) is smaller than the house-sparrow (*Passer domesticus*) and has a black patch in the middle of the white feathers on each side of the neck. There are also two distinct bands of white across the wing in place of one as in the ordinary sparrow. The so-called hedge-sparrow, or Dunnock (*Accentor modularis*), is wrongly named, says Mr. Tegetmeier:—

> It is a purely insect-eating bird, and neither in its structure, habits or food, is it closely related to the house-sparrow. It does not occur in large numbers and is highly beneficial as an insect destroyer.

An American report of 400 pages by the eminent ornithologist, Dr. C. H. Merriam, related the destruction effected by the sparrow in the United States. Particulars of wicker, wire, and other sparrow traps are given. In some parts of the country an arrangement of four ordinary bricks with short pieces of stick is used.

The food of sparrows for May to August is given as follows:—

> May.—Customary food: Corn; vegetable matter; seeds. Occasional food: Young pea-pods and leaves of peas; gooseberry blossoms and young gooseberries; small beetles; caterpillars of the brimstone moth and white cabbage butterflies; turnip seed; hay seed; sprouts of young barley half an inch long; pollen of the sycamore and apple; mangold leaves.
>
> June.—Customary food: Corn; vegetable matter; seeds of various sorts; peas. Occasional food: Gooseberries and other fruit; lettuces; small beetles; mangold leaves.
>
> July.—Customary food: Young wheat, barley, and oats; vegetable matter; seeds of various weeds. Occasional food: Peas; small beetles; beans; seeds of wild spinach.
>
> August.—Customary food: Wheat, barley, oats. Occasional food: Seeds of corn, bindweed, knotgrass, &c.; aphides, small beetles, daddy longlegs (*Tipula*), caterpillars of *Teras Contaminana*, moth of *Crambus culmellus*.

It is well known that sparrows when taken in large numbers may be advantageously utilised as food.

A METHOD OF PRESERVING EGGS.

M. André, of Arnoux, recently described before a Paris medical society a practical means of preserving eggs for several weeks, allowing of their safe transport to the troops and to prisoners. The method consists in covering the egg with a hard envelope which prevents the penetration of the air. The new-laid egg is wrapped round with material steeped in liquid sodium silicate, so-called mineral glue, and then left to dry in an airy place for about twelve hours. At the end of this time the jacketed egg is of the consistency of a stone and entirely resistant to shock. When required for consumption it suffices to steep the egg in tepid water in which the mineral glue readily dissolves, or the silicated envelope may be cut off with a knife in the same way as fruit is peeled. 520 eggs which travelled for a month under the most exacting conditions arrived intact and in an excellent state of preservation.

HEALTH AND SANITATION IN NIGERIA.

FROM the medical section of the delayed report of Sir F. D. Lugard, Governor-General, on the Blue-book of Nigeria for the year 1915, just issued by the Colonial Office, it appears that the native population of the Northern Provinces is roughly estimated at 9,500,000 and that of the Southern Provinces at 7,805,000—a total of about 17,500,000. The average density in the Northern Provinces is about 37 to the square mile and in the Southern Provinces about 105. In the Northern Provinces at the end of 1915 there were about 700 Europeans, of whom some 300 were officials, and in the Southern Provinces about 2000 Europeans, of whom 800 were officials.

The general health of the colony was normal during the year. Compulsory registration of births and deaths only obtains in Lagos and Ebute Metta, and even in these places statistics are unreliable. The most prevalent general diseases are rheumatism and anæmia. Malaria is the commonest insect-borne disease, but small outbreaks of yellow fever have occurred on four occasions at different places in the Southern Provinces amongst the native population only, and one European contracted this disease in the Northern Provinces. A mild form of sleeping sickness is endemic in certain parts of the Niger Delta; the same disease is also found along the banks of the River Benue. Blackwater fever has shown a steady decline since 1910—this follows very closely the malarial fever curve. Considering the largely increased European population the decline of malaria and blackwater fever is significant. Cases of pulmonary tuberculosis were observed more frequently than in former years. Although confined for the most part to the humid Southern Provinces, a few cases have also been seen amongst the natives in the drier Northern Provinces. In the opinion of the medical and sanitary officers this disease is on the increase, and often assumes a very virulent form. There were no cases of beri-beri seen in the prisons during the year. Among the natives of the Cross River the disease is not unknown.

The returns do not in any way represent the true incidence of venereal diseases in the community. Syphilis and gonorrhœa are common diseases all over Nigeria except in the pagan districts of the north, where the natives are reputed not to intermarry with those of other tribes. Helminthic infections are so prevalent that it would be difficult to find a native who does not harbour one at least of the three most common parasites. The percentage of the population infected with ankylostomiasis is very high—probably over 80 per cent. in certain areas—but the infection seldom produces clinical symptoms. It is believed to be often associated with severe cases of diarrhœa and dysentery.

The limitations which the advent of war had imposed upon sanitary activity in the course of the second half of 1914 remained throughout the whole of 1915. Under the circumstances the Northern Provinces should be accounted fortunate, as visitations of epidemic diseases were few. The most unfortunate sanitary legacy bequeathed by 1915 was the fact that it had become necessary to recognise enteric fever and tuberculosis as naturalised members of the community of endemic diseases. A European, a member of the medical staff, succumbed to the former. An improved water-supply has been provided for Lagos. Considerable attention was given during the year to the important question of segregation of the European population at many of the leading political and commercial centres. Definite areas were arranged and, although immediate results cannot be obtained in all instances, progress is gradually being made as opportunity arises and means become available.

In the Northern Provinces the principal hospitals and dispensaries are at Zungeru, Lokoja, Kaduna, and Kano. 812 Europeans and 15,887 natives were treated as out-patients and 325 Europeans and 4364 natives as in-patients; 14 Europeans and 200 natives died. In the Southern Provinces the chief hospitals and dispensaries are at Lagos, Warri, Calabar, Ibadan, and Onitsha. In

these there were treated during the year 411 Europeans and 76,872 natives as out-patients and 1656 Europeans and 9309 natives as in-patients; 12 Europeans and 760 natives died. The Leper Asylum at Yaba and the leper settlements at Ibusa, Onitsha, Okhanam, and Illah had 20, 133, 49, 65, and 32 inmates respectively during the year.

THE CULTIVATION OF JALAP.

To the Editor of THE LANCET.

SIR,—Among the herbs recommended for growing in England I should like to know if jalap has ever been tried. I first saw it in a Norfolk garden, and I now grow it as a creeper at my Hampshire cottage. It bears a beautiful convolvulus flower in the autumn. It produces a few tubercles each year, but I have no knowledge of their medicinal value.—I am, Sir, yours faithfully,

Devonshire-place, W., May 8th, 1917. GEO. H. SAVAGE.

*** The dried tubercles of jalap (*Ipomœa purga*) yield about 10 per cent. of official resin, containing jalapin and scammonin.—ED. L.

A LOST STETHOSCOPE.

To the Editor of THE LANCET.

SIR,—The other day a patient of mine was walking on Crow Lane, which is situated between Newton-le-Willows and Earlestown, when a rapidly-driven motor passed him, from which dropped an object that he brought to me.

It is a stethoscope made of nickel-plated material with the chest- and ear-pieces of pure tortoise-shell. I should say it was of more than ordinary value and should be pleased to forward it to any medical man who may have lost one answering to that description in this locality.

I am, Sir, yours faithfully,

M. C. S. LAWRANCE.

100, Market-street, Earlestown, Lancs., May 8th, 1917.

TWILIGHT SLEEP.

A CORRESPONDENT suggests that we should comment upon the advertisement methods of a nursing home where this treatment is in use, but it seems to us that the public will see at a glance what impression is intended to be produced.

Jupiter.—The administrative orders have recently been so frequently altered that reference to your Local Medical War Committee is the only course to be safely recommended.

METEOROLOGICAL READINGS.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.*

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C. 2.

MANAGER'S NOTICES.

ALTERATION IN THE PRICE OF "THE LANCET."

INCREASED war expenses and cost of production necessitate an increase of the price of THE LANCET. Commencing with the new year, the price was raised to 8*d*. The rates of subscription remain as revised in October.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C. 2, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given on page 55.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied.

Communications, Letters, &c., have been received from—

Goulstonian Lectures
ON
PARATYPHOID INFECTIONS.

Delivered before the Royal College of Physicians of London.

BY CHARLES HEWITT MILLER,
M.D. CAMB., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN, LONDON HOSPITAL; PHYSICIAN, VICTORIA HOSPITAL FOR CHILDREN; LATE MAJOR (TEMP.), R.A.M.C.

LECTURE I.

MR. PRESIDENT AND GENTLEMEN,—I wish first to offer my thanks to the College for the honour done me in selecting me to give these lectures. I am anxious also to ask for your indulgence as the difficulties of preparing the lectures in war time have been very great.

INTRODUCTORY.

I have taken paratyphoid infections as my subject as it is one of very great interest in the medical history of the war and it promises to be of continued importance to this and other countries after the war has ended. At this period it might be objected that the time has not yet come for the consideration of a subject of this nature; for the observations and reports that are being made are not available for reference. The subject, therefore, is not yet ready for final consideration. This is especially true of the bacteriological investigations, but clinical observations can always be recorded and reviewed. At this juncture a clinical study of paratyphoid infections is not out of place, for a great change has come over the clinical character of these diseases, and descriptions made in the first two years of the war will differ materially from those of the third and subsequent years.

The bacteriology and serology of these diseases are complicated, and the literature on the subject is becoming extensive. I do not propose to deal with the bacteriologist's side of the subject at all fully. But in these, as in all infections, the need is illustrated for close coöperation between the wards and the laboratory; for it is essential that both the bacteriologist and the physician should be able to regard the subject from the point of view of the other. In this respect I have been fortunate in being associated with Major H. L. Tidy, R.A.M.C., for whose help and coöperation I am very grateful.

The bacteriological aspect of these diseases is necessarily of great importance, for the making of an absolute diagnosis rests with the bacteriologist. Further, he alone can say when a patient is free from infection. The clinician, on the other hand, has to make the first diagnosis; but he cannot go further than diagnose the "enteric" group;[1] it is impossible for him to diagnose typhoid fever from paratyphoid fever and the paratyphoid fevers from each other. Several points of diagnostic difference have been recorded, but they do not hold good, for though there may be a tendency for one organism of the group to produce a certain set of conditions more frequently than the others, instances of similar conditions produced by the other organisms can usually be found. It does not follow that a description of typhoid fever would be applicable to the paratyphoid fevers. The organisms of the latter diseases have apparently a wider range of infection in the human body, and in addition to the "enteric" symptoms may cause some systemic disease or group of symptoms that will mask the nature of the infection.

HISTORICAL SUMMARY.

It will be my endeavour to give a description of these infections as I have seen them and as they have been recorded by other observers. But, first, it will be convenient to give a brief historical summary of the paratyphoid organisms and how they were found to be associated with disease.

In 1896 Achard and Bensaude[2] gave an account of a case of apparent enteric fever in whose urine they found a bacillus which was not *Bacillus typhosus*. They called it paratyphoid.

In 1893 Norman Gwyn[3] described a case of enteric fever caused by an organism with which the agglutination tests for typhoid were negative all through the illness.

In 1900 Harvey Cushing[4] described an organism obtained from the pus of a costo-chondral abscess following an attack of apparent typhoid fever. This organism was not *Bacillus typhosus*.

In August, 1900, and again in 1901, Schottmüller[5] described bacilli which presented characteristics between *Bacillus typhosus* and *B. coli*, which did not give the agglutination reactions for *B. typhosus*.

In 1901 Durham,[6] in discussing agglutinin gave a classification of organisms of typhoid-like and colon-like morphology, among which the paratyphoid organisms would find places.

In 1902 Buxton,[7] in working on these and allied organisms, split the paratyphoids into two groups, α and β; α is nearer *B. typhosus*, β is nearer *paracolon*.

In 1904 Firth[8] gave a comprehensive account of paratyphoid A among British troops in India. Since then important contributions to our knowledge have been made by officers of the Royal Army Medical Corps, especially by Birt, Statham, Harvey, Grattan, and Wood, their observations being chiefly on our troops in India.

In 1912 Bainbridge[9] gave the Milroy lectures on Paratyphoid Fever and Meat Poisoning. Employing the absorption methods as described by himself, Castellani, and Boycott, he was able to put on a definite basis the differences between paratyphoids A and B and the organisms of meat poisoning, *B. suipestifer* and *B. enteritidis* of Gaertner.

INCIDENCE BEFORE AND DURING THE WAR.

Before the war occasional cases of enteric fever were seen in which the agglutination test was repeatedly negative. On making further examination with a culture of *B. paratyphosus B* a positive result was sometimes obtained. Such an occurrence is within the experience of most physicians.

Boycott[10] has calculated that each year in London 100 cases of clinically enteric fever might be expected to be paratyphoid B fever, and that in England 3 per cent. of the cases which run the clinical course of enteric fever are really paratyphoid fever. They also form a fraction of enteric cases in statistics that have been compiled in Germany and America.

In India it has been calculated that in addition to the cases of enteric fever caused by *B. paratyphosus A* a large number of the cases called "pyrexia of uncertain origin" are really paratyphoid A.

Paratyphoid fever in Europe is more frequently B than A; in India A is common and B very rare. If paratyphoid A fever has occurred in England before 1914, it must have been very rare, though it has been seen in France, in Germany, and in America.

Since the outbreak of war opportunities for the study of paratyphoid infections have increased enormously. At first paratyphoid B fever was very rife in Belgium and Northern France; later paratyphoid A infections occurred. With the Gallipoli campaign the number of paratyphoid cases was greatly increased, the paratyphoid B cases being more numerous in the early autumn and A cases in the late autumn.

The cases of paratyphoid fever which have come under my observation have been patients at the British Red Cross Hospital, Netley. At this hospital patients have been received from every front. Comparatively few were admitted with the diagnosis of enteric fever. The majority were wounded or sick men, who started their symptoms of enteric fever a few days before or after admission. Men who had been buried, or gassed, or who had trench feet or wounds of the chest seemed particularly liable to contract the infection. In all 500 cases of paratyphoid infections have been in the hospital between October, 1914, and February, 1917, and there have been opportunities for seeing the cases in all stages and through all stages. Many of these patients have been double, and even triple, infections of the enteric group. Some have been mixed infections with bacillary and amœbic dysentery. The majority of the multiple infections came from Gallipoli.

[1] The term "enteric" will be used to denote the typhoid and paratyphoid fevers. Typhoid fever will be used for infection by *B. typhosus*, and paratyphoid fever for infection by *B. paratyphosus A* and *B*.

CLINICAL TYPES OF PARATYPHOID INFECTIONS.

The majority of observers do not go further than to say that paratyphoid fever closely resembles mild typhoid fever, or is typhoid fever on a small scale. Firth[11] says that paratyphoid infections may be mild or as severe as in genuine typhoid. This statement is confirmed by the cases seen during the war, for all degrees of severity have been seen varying from an apyrexial type to the severest form of enteric fever. Certainly the cases of paratyphoid fever seen in the first two years of the war were more severe than the cases of typhoid fever among the inoculated. The features of the classical description of typhoid fever are very commonly seen in paratyphoid fever—i.e., headache, diarrhœa, the type of temperature, the roseola, the enlarged spleen. But these symptoms and signs may be present in a patient whose condition has a resemblance to some other disease—e.g., influenza, rheumatism, and nephritis.

CHART 1.

Mild case of paratyphoid B. Short duration. T. steady after third week. Sudden onset, shivering, headache, malaise. T. 103·2°, P. 76. Tongue clean, constipation; spleen palpable on ninth day; no spots. Stools = para. B.

As in typhoid fever, the paratyphoid organisms produce a bacillæmia, and it is therefore possible for any part or parts of the body to be infected or affected. The paratyphoid organisms have not the same limited affinity for the lymphatic tissue of the intestine as the *Bacillus typhosus* but tend to produce lesions in various parts of the body. The effects on the different anatomical structures of the body may be summarised thus:

1. Respiratory system: Rhinitis; pharyngitis; laryngitis; tracheitis and bronchitis; broncho-pneumonia and pneumonia; pleurisy, dry, serous, sero-fibrinous, purulent.

2. Alimentary system: Gastritis; enteritis, with and without ulceration of the lymphatic tissue; colitis, ditto; appendicitis; inflammation of bile-ducts, gall-bladder, and liver.

3. Urinary system: Nephritis; pyelitis and pyonephrosis; cystitis.

4. Skeletal system: Osteitis; synovitis, arthritis, and peri-arthritis; myositis (?), myalgia.

5. Vascular system: Phlebitis; arteritis; possibly endo-, myo-, and pericarditis; septicæmia.

In addition, inflammation of the middle ear, iris, conjunctiva, meninges, testicle, and epididymis have been seen.

Many of these anatomical lesions are more properly considered as complications, and for clinical purposes other forms of classification are more suitable. Dr. E. Stolkind,[12] of Moscow, speaking at the Royal Society of Medicine, gave the following classification: (1) the influenzal or respiratory form; (2) the gastro-intestinal form; (3) the choleraic form; (4) the typhoid form. This classification indicates that in Dr. Stolkind's opinion paratyphoid infections may be of a varied nature. He also said that clinically and pathologically there is no difference between paratyphoid A and B. He laid special stress on the frequency of the respiratory or influenzal type.

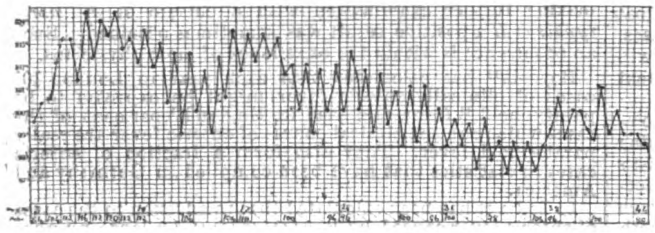
In collecting the particulars of the cases that came under my observation I found that there was a great variety of clinical types among the cases. The initial stages of the disease frequently resembled other diseases, but later on there would be a closer resemblance to enteric fever. It is convenient to classify them under certain headings for the purposes of description, but I wish it to be understood that the typhoid type is to be regarded as the parent type and the others as the offspring.

The headings under which I propose to classify paratyphoid infections are: (1) the typhoid; (2) the dysenteric; (3) the biliary—i.e., jaundice and cholecystitis; (4) the urinary—i.e., nephritis, cystitis, &c.; (5) the rheumatic or arthritic; (6) the respiratory—i.e., bronchitis, pneumonia, and pleurisy; (7) the influenzal; (8) the septicæmic.

I. THE TYPHOID TYPE.

The typhoid type is the one most commonly seen and recognised, at any rate among the uninoculated.

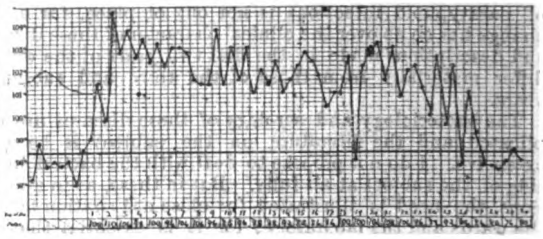
General Description.



The period of *incubation* is difficult to calculate. The patient is usually unable to give any information, for the possibilities of infection on any one day are the same as on any other. Also, the patient may have been an unaffected carrier for some time, and it only required some circumstance to lower the resistance and so cause symptoms to develop. But judging from such information as was available the incubation period is from 12 to 20 days.

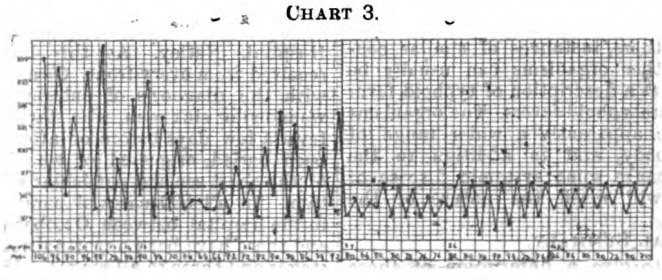
The *onset* is either gradual or sudden. The gradual onset is rather more frequent than the sudden. In the gradual onset the more common symptoms are general slackness, increasing headache, loss of appetite, thirst, pains in the back and legs, dizziness, inability to keep warm, and insomnia. In the sudden onset shivering, fainting, and vomiting are of frequent occurrence. Sometimes sudden intense headache is the first symptom.

Abdominal pain is common; it is usually moderately severe and colicky, and is not localised. *Diarrhœa* occurs in more than half the cases; it is usually of short duration and is followed by weeks of constipation. *Nose-bleeding* occurs in about one-sixth of the cases.



There is usually a noisy *cough* and a red, swollen throat; at first there is very scanty sputum. Less commonly there are deafness and blindness and photophobia.

CHART 2 A.



Severe case of paratyphoid A, enteric type. October, 1915, jaundice followed by debility. Jan. 17th, 1916: Three days' illness; pain in stomach, headache, diarrhœa; Feb. 12th: T. rising; Feb. 17th: T. 104·4°, delirium, spleen +, spots, constipation. Agglutination + para. A. Urine = para. A. Stools = *B. coli*.

CHART 2 B.

Enteric fever, paratyphoid B. Severe case of classical typhoid type. Sharp initial rise and defervescence. Patient not inoculated. Agglutination + para. B. Copious rash, spleen +, diarrhœa, delirium. Trench feet.

CHART 3.

Irregular type with remissions of 3° and 4°. Also period of swing, fifth week, before finally settling. On admission debility, constipation, T. rising seven days. Tongue dry, white fur, abdominal distension, spleen +, spots, delirium. Para. A in stools, agglutination negative. Inoculated (2) seven months ago.

[11] Firth: Journal of R.A.M.C., 1904, ii.
[12] Proceedings R. Soc. Medicine (Med. Sect.), Nov. 23rd, 1915.

The *aspect* of the patient is not often alarming. The cheeks and ears are flushed, the pupils moderately wide, and the skin dry. But in severe cases the patient has the same appearance as in severe cases of true typhoid, and in some cases, especially those in which the lungs are affected early, there may be profuse sweats.

The patient is drowsy and apathetic; he can be easily roused; the memory especially for the details of the onset of symptoms is poor. He is content to lie curled up in bed and only wishes to be kept warm and left undisturbed. If asked, he will probably complain only of headache or backache. The headache is most often vertical, but may be frontal or occipital.

The *tongue* varies greatly in different individuals. Generally speaking, the tongue is more frequently moist than in true typhoid. It is commonly pale, with yellowish-white fur on each side of the middle line. The edges and tip are red and moist. The impressions of the teeth are very noticeable. In other cases the tongue is dry, covered with a brown crust, and is cracked. In the severest cases the tongue is tremulous and is put out with uncontrollable shaking jerks. The condition of tongue need not bear any relation to the temperature. I have seen a dry brown tongue with a temperature of 99° F., and a moist clean one with a temperature of 104°.

Temperature and Pulse.

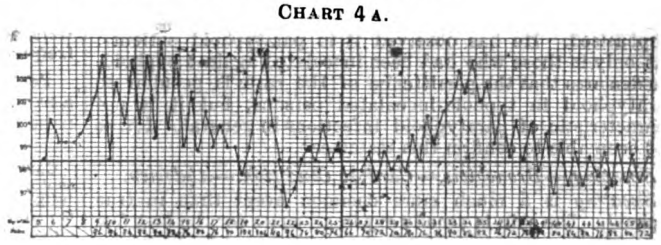
The *temperature* is very varied.

1. The case may be apyrexial except for an occasional evening rise to 99° or 100°. In these cases there may have been a very short febrile period before the patient came under observation. This condition is also seen after defervescence following an acute attack, especially if it has been mild.

2. The period of pyrexia may be very short. This is more often seen when the original rise is sudden but not high. (Chart 1.)

3. The temperature may be of the classical typhoid type, with the initial rise either gradual or abrupt, and remissions beginning about the tenth to fifteenth days. (Charts 2 A and 2 B.)

4. The remissions in the temperature may be very pronounced all through the pyrexial period; this type is also often associated with sweating. (Chart 3.)



5. The pyrexial period may be prolonged by recrudescence. (Chart 4A and 4B.)

6. The temperature may be of an irregular type; it may resemble the temperature of a hectic consumptive; it may be of an inverted character, with morning rises and evening falls. Briefly, it may be of such a type that it cannot be classified. This is the largest group of all, for few of these cases resemble each other as regards pyrexia. It does not seem possible to lay down rules with regard to the temperature either with regard to rise, maintenance, or defervescence. But it frequently happens that if the temperature reaches its highest point quickly, the duration of fever is shorter than in other cases where the rise has been by gradual steps.

The *pulse* behaves in a more orderly fashion than the temperature and is of importance in diagnosis both for its own characteristics and its relationship with the temperature. The pulse is soft, easily compressed, often dicrotic and relatively slow. Slowness of the pulse with a rising temperature is the most important of the early signs of paratyphoid fever. It is even more constant and more pronounced than in typhoid fever. Thus a pulse of 76 with a temperature of 101° F., or 82 with 102°, or 90 with 103°, are seen quite frequently in favourable cases. Above 103° there is commonly a "loosing" of the pulse, and it may quicken to 120 with a temperature of 104°. It may often be noticed that if the pulse is rapid in the early days of the fever the temperature may go high, and the patient is probably in for a severe attack with pronounced nervous symptoms. The pulse, therefore, has a prognostic as well as a diagnostic value. As the temperature comes down the pulse becomes slower and slower and may go down to under 50. As convalescence proceeds it gradually comes back to normal.

Carles and Marcland[13] have made an exhaustive study of the pulse in paratyphoid fever and have come to similar conclusions. They have described the relationship between pulse and temperature graphically by curves. They describe four types.

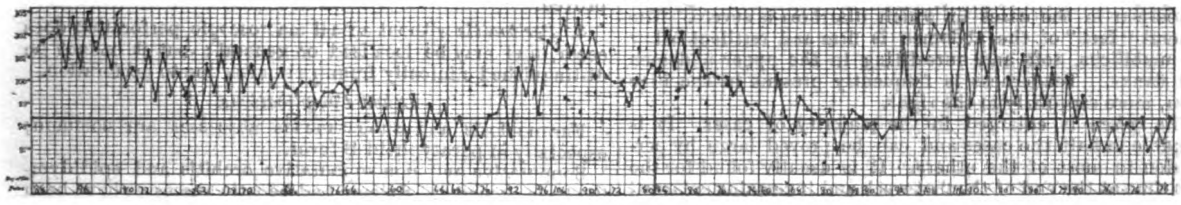
CHART 4 A.

Case 2, H. H. Enteric fever, paratyphoid B. Remittent T., relapse of classical typhoid type. Perforation 20th day; operation. Relapse 30th–40th days.

1. The commonest or angular form; the temperature curve falls obliquely, while the pulse curve remains horizontal and at normal the two curves meet.

2 and 3. Parallelism, distant and absolute. In the former the curves approach, but do not meet, at normal; in the latter the curves remain apart.

4. The inverted angular type, only seen in very grave cases; the curves cross each other—i.e., the pulse increases in rapidity out of ratio with the temperature.



Such elaborate and artificial methods are not for everyday use, but it is demonstrated that if the pulse is slow in relation to the temperature a definite diagnostic point is gained, and if, with the symptoms pointing to enteric fever, a relatively rapid pulse is found the prognosis is serious.

The arterial tension is low. J. D. Rolleston[14] has shown that in typhoid fever the tension is low in 93 per cent., and that the lowering is in direct relation to the severity of the illness. The same is found in the paratyphoid fevers; the low tension, 90 to 100 mm. Hg, is found to persist for the first week or two of convalescence.

The Rash.

The rash appears for the first time about the end of the first week. It is of different varieties.

CHART 4 B.

Enteric fever, double paratyphoid infection. Prolonged T. with recurrent exacerbations and relapse. On admission diagnosis of hysteria, shock, and debility. Para. A and B in stools; agglutination + A and B. At first nervous symptoms pronounced, later typical enteric. Relapse (not shown) after 36 days normal T.; T. 103·6°, P. 128. Later periostitis of tibia.

1. The commonest variety is the roseola which is seen in true typhoid. The spots appear on the lower part of the chest and the abdomen. Subsequent crops are of frequent occurrence, and fresh crops may be seen in convalescence without there being any exacerbation of symptoms or a rise of temperature.

2. The second variety of rash may be regarded as characteristic of paratyphoid fever. It consists of larger spots, of irregular outline, red with a blue tinge, raised, not fading completely on pressure, and leaving a freckle-like mark of pigmentation after they have disappeared.

3. The third variety is rare. Cyanotic subcuticular patches of irregular shapes and sizes are sometimes seen in severe cases. These patches may be the only evidence of a rash, or they may be mixed with the other forms.

[13] Archives des Malad. du Cœur, Année ix., No. 3, 1916.
[14] J. D. Rolleston: Medical Press and Circular, March, 1916.

The amount of rash may vary from one or two spots to a general covering of trunk, limbs, and head. The diagnosis of measles or rubella is sometimes made in these cases of generalised eruption. In the cases of morbilliform rash that I have seen the large dusky paratyphoid spots have been very numerous.

CASE 1.—J. D., admitted from France for frost-bite. On the fifth day after admission the temperature began to rise, and in 48 hours was 104·6° F. He was very ill. There were delirium, diarrhœa, a palpable spleen, pulse of 110. On the sixth day spots began to appear, and in two days he was covered from head to foot with spots of the larger variety and also a few small pink spots. On the twenty-eighth day the temperature was normal; the spots had disappeared leaving a brown stain. No previous inoculation. Agglutination +++ to *B. paratyphosus B*

Labbé [15] says that the persistence of spots for some days after the cessation of fever is a point which has been emphasised. He has observed it in paratyphoid patients, but only in those who had been inoculated against typhoid. He declares that the persistence of the rash is peculiar to paratyphoid in typhoid-inoculated persons, but it is not characteristic of paratyphoid infections in general. I have not been able to confirm this statement.

Sweating.—Bronchitis.—Cardiac Condition.—Abdomen.

Sweating is a much more common event than in true typhoid. The skin is usually dry in all cases for the first few days, but in some cases sweating is profuse and begins early. It is so severe that sometimes the question of malaria has to be considered. When the illness begins with shivering and a rise of temperature which is followed by a profuse sweat the similarity is great. But as the temperature does not come down with the sweating the resemblance ceases to be close. The sweating at night is a great nuisance to the patient, as it necessitates frequent changes of clothing and spoils his chances of sleep.

Bronchitis occurs with great frequency during the first ten days. It is of short duration, and the cough is distinct from the initial cough which is due to the condition of the throat. Basal crepitations are also common about the eighth day, when the temperature is 103° F. or higher. In the milder cases the bases remain clear. The more serious bronchial and pulmonary conditions will be described later.

The heart.—Cardiac inflammations are rare. I have not seen a case of pericarditis nor of endocarditis, but they have been recorded. Myocarditis has been diagnosed by some observers, but this statement must be accepted with reserve. Two conditions of the heart are worthy of note.

1. A diminution of the area of cardiac dullness associated with a shortening and a lessening of the intensity of the first sound. This phenomenon is not perceptible until the fever has lasted at least a week.

2. Cardiac dilatation occurs in a few cases, but it is usually late in the course of the illness.

The abdomen.—A moderate degree of distension is almost always present. There may be distension to the degree of meteorism in the cases in which diarrhœa is severe. The general "feel" of the abdomen is firm and resilient below the umbilicus, soft and unresisting in the upper abdomen and flanks. Tenderness is frequently present in the iliac fossa, more especially in the right.

The *spleen* is enlarged in the majority of cases. It is palpable in half the cases and can be proved large by percussion in most of the others. It is usually found for the first time at the end of the first week and it remains enlarged during convalescence. Further, the spleen is very often painful. Pain in the left hypochondrium is a frequent symptom of the early days, and the pain may last a long time. It is stabbing in character and is made worse by deep inspiration and coughing. It sometimes raises the suspicion of left-sided pleurisy, for the pain is like that of an inflamed serous membrane.

The *liver* edge is occasionally lower than normal, and deep tenderness over the area of the gall-bladder is fairly common. Sometimes it is of short duration; at other times it is recurrent and accompanied by spasms of colicky pain.

The stools.—In nearly all cases there is an initial diarrhœa, the stools being of liquid fæcal matter. In a few cases the diarrhœa persists and there may be 8 or 10 actions in the 24 hours. In such cases the stools may be of the "pea-soup" variety. But most commonly diarrhœa only lasts two or three days and is followed by constipation.

Intestinal Complications.

1. *Hæmorrhage* occurs as in typhoid fever, but is not so frequent.

[15] Labbé: Med. Press and Circular, 1915.

At the highest estimate it is not more than 5 per cent. Labbé mentions it as occurring in 2 cases out of 45; Torrens and Whittington [16] report cases of severe hæmorrhage occurring in paratyphoid B; Dawson and Whittington [17] report it as a cause of death in 2 cases and with toxæmia in 3 more. I have seen it in 2 cases only, and in neither case was it severe. An occasional streak of blood or small clot is very common.

2. *Perforation* is rare, but symptoms that cause perforation to be suspected are more common.

It was found in 3 autopsies out of 17 [17]; of these, 2 were paratyphoid B and 1 was A. In another series [16] there were 3 perforations due to paratyphoid B and 1 to A. Moorhead mentions 1 case of perforation in which there was a mixed infection by paratyphoid B and *Entamœba histolytica*. Other writers [18] mention it as occurring in paratyphoid B as frequently as in typhoid fever.

Perforation occurred in two of my cases, one of which was a paratyphoid B infection, the other a mixed infection by paratyphoid A and B and *B. dysenteriæ* (Shiga). The following case is of interest:—

CASE 2.—H. H., admitted from Mediterranean, 3.1.16, for chronic septic focus on left arm; inoculated twice against typhoid, August, 1915. History: Headache for four days; abdominal pain; constipated. On admission, T. normal; rose to 100·2° F. next morning, and gradually climbed to 103°, and after swinging with remissions of 3° came to normal on Jan. 17th. (Chart 4 A.) Tongue brown and dry; spleen palpable; abdomen distended during febrile period.

Jan. 18th: 5 A.M.: Acute abdominal pain in right iliac fossa; vomiting. 7.30 A.M.: Right lower abdomen rigid and tender; little movement; tongue dirty; T. 101·4°, P. 100. 10.45 A.M.: Right side of abdomen acutely tender; T. 102·2°, P. 100. Aspect suggests peritonitis. 11.30 A.M.: More comfortable; very little tenderness; looks much better. My surgical colleague, Major C. Nitch, R.A.M.C., saw him and decided to wait. (Up to this point the course had been similar to that of another patient who had been quite well again in two days). 2 P.M.: More tender again. 4 P.M.: Further vomiting. 7 P.M.: Operation by Major Nitch. Incision below umbilicus; bile stained fluid everywhere; intestines red, rough, and covered with lymph; small perforation discovered in ileum 8 inches from ileo-cæcal valve; suture; recovery.

Jan. 28th: Typical relapse lasting 10 days. Ultimately a good recovery. Agglutination positive to *B. paratyphosus B*; organism recovered from stools.

3. *Appendicitis.*—Typical symptoms and signs of inflammation of the appendix are fairly common.

The case quoted above resembled appendicitis in many respects. But actual inflammation and ulceration of the appendix do occur for they have been found post mortem, [19] and I have seen two acutely inflamed appendices removed during the acute stage of paratyphoid B fever. Stolkind also mentions appendicitis paratyphosa. Rathery and his colleagues [20] mention appendicitis occurring in the course of, or convalescence after, paratyphoid B fever. In their experience it is a mild condition; they have not seen a case of gangrene nor perforation of the appendix. The frequence of appendicular symptoms is apparently a peculiarity of paratyphoid B. I have not seen a case of appendicitis due to paratyphoid A, but I have seen mild cases that were not proved.

4. *Peritonitis* without actual macroscopic perforation does occur, and may be localised or general; but it cannot be distinguished clinically from peritonitis due to perforation.

Other Complications.

Furunculosis and subcutaneous abscesses are common, especially in paratyphoid B fever.

Suppurative and non-suppurative orchitis and epididymitis have occurred. Splenic and hepatic abscesses have been discovered post mortem. An abscess of the brain in paratyphoid B fever has been reported by Scott and Johnston. [21] Osteitis, periostitis, and abscesses of bones, especially of the ribs and tibiæ, have occurred among my cases and are reported by others.

Arterial complications are rare. Thrombosis has been found in different arteries, most frequently in arteries of small size. Macadam [22] has described a case in which thrombosis was found extending from the left internal carotid artery, through the middle meningeal to the lenticulo-optic and lenticulo-striate branches. The infection was paratyphoid B. Phlebitis will be considered as belonging to the stage of convalescence.

Relapses occur in different percentages according to different observers.

[21] Scott and Johnston: THE LANCET, 1915, i., 852.
[22] Macadam: Journal of R.A.M.C., xxvii. (No. 4), 499.

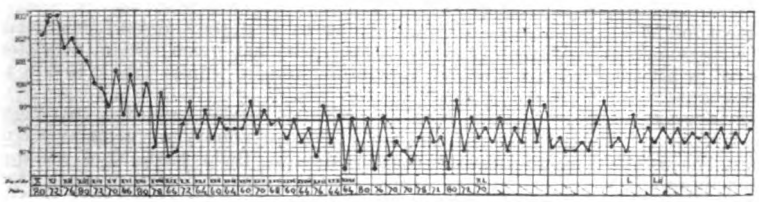
Wiltshire[23] reports 7 in 98 cases; Labbé[24] quotes a similar proportion, 3 in 45; Robinson[25] says that relapses of brief duration are not uncommon. On the other hand, Dawson[26] says that re-infections are uncommon.

In my cases the percentage is about 8, and in quite a fair number those who relapse have more than one relapse. The relapses become milder as time goes on. In one case there was a relapse after five weeks of normal temperature; in another case there were 5 relapses, each one being milder than the previous one.

Kennedy and Russell[27] have reported a case of paratyphoid A fever with relapses on the thirty-fifth, fifty-eighth, and ninety-fifth days, during which the organism was isolated from the blood.

There were more relapses in the patients who came from Gallipoli than in those who came from France. It is possible that the greater prevalence of double infections in the former could account for the greater frequency of relapses among them.

Convalescence.



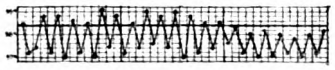
The behaviour of these patients, when the acute stage is over and they are well enough to be up and about, is very disappointing. Their progress is slow; their normal vigour does not return; they constantly say that they feel weak and good for nothing. Lassitude, morning headache, lack of appetite, inability to sleep in the early part of the night and waking up unrefreshed, are frequent complaints. This is a very different picture from the convalescence of typhoid fever.

How much these complaints are due to paratyphoid and how much to the circumstances of active service it is impossible to say. In a base hospital in this country patients remain until they are well, and their condition following the termination of an acute illness can be studied. These men are still infected and they are suffering from an infection the virulence of which is on the wane. The infection may not be capable of demonstration at each examination of excreta. But repeated examination will often reveal the presence of a paratyphoid organism. This does not mean that these patients will ultimately become chronic carriers, but they have not yet thrown off their infection. It is too early yet to say what percentage of infected men will become carriers.

Temperature.—Commonly there is an occasional evening rise to 99° or even 100° F. during convalescence, but the arresting feature of the temperature chart is the amount of "swing." A difference of 1½° and even more between the morning and evening temperature is quite common; the swing gradually lessens as time goes on. Putting the patient back to bed and allowing him only a fever diet does not affect the temperature, and in my opinion it is a mistake to do so. (Charts 5 A and 5 B.)

The *circulatory system* is also in an unsatisfactory condition. The area of cardiac dullness, which has shrunk during the febrile period, may gradually return to normal in a patient making satisfactory progress and taking exercise. But in many others it is common to find a heart that is dilated with a widely diffused impulse and a displaced apex beat. The action is rapid and the heart races on exertion or excitement. The patient complains of cardiac pain and palpitation. A few days in bed, limitation of food and tobacco, and attention to the stomach and bowels will improve the condition. In some of these patients there are tremors of fingers and copious axillary sweating. In this class of patient the heart-rate is not increased in sleep. In others the condition is more obstinate, and these patients go to form a portion of the men who are invalided for "soldier's heart," unless their hearts will respond to education by graduated exercise. Many of these conditions, "irritable heart," "D.A.H.," &c., originate from some infective disease, and the paratyphoid infections are certainly capable of producing these conditions.

CHART 5 A.



Irregular type of T. Prolonged irregular T. for four weeks after defervescence. Enteric fever, paratyphoid B. Patient inoculated for typhoid (2) January, 1915. Headache, diarrhœa, spots, dry furred tongue, spleen +. Agglutination 12th day +++ typh. and para. B. Stools = para. B.

The peripheral circulation is bad. Cold, blue hands and feet are very common. This will occur in men who have never suffered from cold extremities before. Polyuria accompanies this condition. In two cases polyuria has been so excessive that they were sent into hospital as diabetes insipidus. One patient was passing over 25 pints a day. In each case there was a history of diarrhœa of short duration, and polyuria began a few weeks later. In each case *B. paratyphosus B* was found in the stools. Vigorous exercise up to the point of sweating was found to be the best treatment for these conditions.

Phlebitis and thrombosis of veins occurred in 5 per cent. of my cases. The veins affected were either the internal saphenous vein, or the small subcutaneous branches of the internal saphenous vein on the calf, or the femoral vein. In one patient who had thrombosis of veins in both legs, phlebitis of the median basilic vein of the right arm occurred. The average incidence of thrombosis would seem to be about 4 per cent. Moorhead had 3 cases; Torrens and Whittington had 3 cases in 100 paratyphoid B and 1 in 50 paratyphoid A. Wiltshire noticed it in 4 paratyphoid B cases in a series of 97. Rathery says that phlebitis is relatively frequent. It certainly seems to be commoner than in typhoid fever.

CHART 5 B.

Prolonged period of swing in paratyphoid A, before settling. Chart shows 11th, 12th, and 13th weeks after acute illness.

[In examining the legs of men whose shins were painful I was struck by the frequency with which a hard, rigid, internal saphenous vein was found at the point where it passed in front of the internal malleolus. It felt like a tendon and could be traced a little way up the leg and felt as a cord going deep into the muscles of the calf. The internal saphenous vein over the calf was usually soft and its contents fluid; occasionally it was thrombosed. But the vein over the internal malleolus was rod-like and solid. It was found that in the enteric wards this condition was absent in only 5 per cent. of cases. In the ordinary medical wards it was absent in 70 per cent., and in surgical wards it was absent in 80 per cent. In some of the cases in which it was present in the medical wards an enteric infection had been suspected but not proved, and in one of the surgical cases *B. typhosus* was isolated from the stools. These veins were also present in some cases where there had been extensive flesh wounds of the thigh, and in two patients in whom the femoral vein had been tied. This phenomenon may turn out to be quite valueless as a diagnostic indication of a previous enteric infection, but it is possibly a sign of a deep thrombosis; its prevalence in the enteric wards is suggestive.]

Constipation in convalescence is frequently troublesome, but a regulation of diet and plenty of exercise will usually overcome it. In other cases liquid paraffin by itself or with cascara may be necessary at first.

Symptoms of *neurasthenia*, apart from the neurasthenic cardiac condition already mentioned, are only too evident during convalescence. Again, whether active service or paratyphoid fever is more to blame is a difficult question to answer. In my experience the neurasthenic state is more common in paratyphoid convalescents than in other cases. Further, the victims of shell-shock, gassing, and burying are especially liable to contract paratyphoid fever, and in their convalescence suffer severely from their nervous symptoms. Insomnia and night-terrors are particularly common among paratyphoid convalescents.

Nervous disturbances of a more definite type have been observed. Three cases of spasmodic asthma occurred in men who had never had asthma before. Severe paroxysmal headache was present in several patients. One patient, whose headache was occipital, suffered so severely that he threatened to do away with himself. Melancholia was seen in one man who had had only a mild attack of paratyphoid B. In all these cases the symptoms were transitory, and in six months' time the patients were fit.

TRENCH SHIN AN INFECTIOUS FIBROSITIS.

BY GRAHAM CHAMBERS,
LIEUTENANT-COLONEL, CANADIAN ARMY MEDICAL CORPS.

UNDER the heading of infectious fibrositis I propose to discuss a condition with a fairly definite symptom-complex, of which the outstanding symptoms are pain and tenderness on pressure over the tibiæ and tibiales antici.

During practically the whole of the time the British Army has been in France and Flanders, also in Greece, cases of this description have been continually observed. Owing to the frequency of involvement of the shin bones, and the fact that the disease is very common amongst soldiers in the trenches, it is usually called "trench shin." Cases occur, however, in men who have never been in the trenches, indicating that this term cannot be regarded as universally applicable. I suggest that the term "infectious fibrositis" be used to designate this and kindred affections, believing as we do that these diseases are of infectious origin, and that the bacteria or their toxins, causing the morbid condition, show marked elective action for fibrous tissue. They attack the fibrous structures of periosteum, ligament, muscle, nerves, and other parts which are rendered vulnerable by cold and wet, or by any disturbance which interferes with the blood-supply to the part, such as the wearing of puttees. The evidence in favour of this view will be given later in this paper under the heading of "Etiology."

Symptoms.

In addition to the outstanding symptoms which have already been mentioned—namely, pain and tenderness in the lower limbs, many others may be present, but most of them are not constant. Fever is practically always present in the early stage of the condition, and is generally rather high when the patient first comes under observation, usually about 102° F., but sometimes as high as 103° or more. In the great majority of cases it disappears within a few days, but there may be variations in this respect, as we shall see when we come to report illustrative cases of the disease. In one of the cases recorded in this paper fever of a low grade lasted for 20 days, but such persistence is, judging from our own experience, rather exceptional. The pyrexia is invariably accompanied by a polymorphonuclear leucocytosis. The association of fever and leucocytosis with the general clinical manifestations of the disease has led us to the assumption that it is of infectious origin. An interesting feature of the blood count is the presence of leucocytosis after the fever has disappeared. In one of our own cases a leucocytosis of 15,500 was still present eight weeks after the disappearance of fever. The pulse-rate nearly always remains below 100, but varies to a certain extent according to the temperature.

Headache is the rule in the early stage of the disease, and is described by some of the patients as being "jumping" or "stabbing" in character and worse at night. The temples and forehead are the most common sites of pain, and the patients frequently state that the headache is intensified by rapid movement of the eyes or pressure on the eyeballs. It is also aggravated by coughing, and is not infrequently accompanied by dizziness. In a few of the cases reported the headache has been universal, and in one described by Hunt and McNee it was so severe that lumbar puncture was performed with the object of excluding meningitis.

As already stated, the commonest sites of pain are the shin bones and tibiales antici muscles. The pain is usually of a dull aching character, increased by movement, and relieved to a certain extent by rest. It is practically always bilateral, but a few cases have recently been reported in which the left shin only was affected. Pain in the back is also a fairly constant symptom. Indeed, it may be said that pain and tenderness on pressure may be present in any part of the surface of the body. The muscles of the arms and thighs are common locations, and in a considerable number of cases the bony prominences and ligaments about the joints, particularly the knees and ankles, are painful and tender. In a small proportion of cases the pain and tenderness may be localised in nerves. A nerve was involved in five of our cases. Of these, the ulnar was the nerve affected in three cases, the median in one, and the radial in one. The symptoms referred to the nerves are those of a neuritis.

The physical examination of the tibiæ does not elicit anything of much diagnostic value, except extreme tenderness on pressure, which has already been referred to as an outstanding symptom of the disease, and I have never been able to satisfy myself that appreciable periostitic thickening is present, and the few skiagrams of the tibiæ which I have had made do not indicate that it exists. In some cases slight redness of the skin over the internal surface can be made out.

Etiology.

There has been a good deal of discussion as to the etiology of trench shin and trench foot, but the causation still remains more or less obscure. Three causative factors—namely, constriction, infection, and exposure to wet and cold—appear to exist.

Constriction.—Amongst the various contributory factors constriction appears to be a very important one. A clinical study of the cases indicates that the frequency of localisation in the legs is favoured by the wearing of puttees. The fact that most cases occur among privates and non-commissioned officers who are in the habit of wearing puttees supports this view. The lower third of the tibia is not commonly involved, because of the protection afforded this part of the leg by the boot. Anything which tends to impede circulation of the limb, such as tightly tied boot-laces or puttees, may thus contribute to the setting up of the condition. This is recognised by the German writers, who give the disease the name "gaiter pain." In addition to obstructing venous circulation, tight bandaging of the legs by puttees tends to produce a continuous loss of heat. This is important, because cold seems to be one of the chief causative agents of the disorder.

Infection.—The view that the disease is primarily due to an infection is gaining more and more adherents, and is supported by the fact that in the Army it is met with almost exclusively in men who have been in or near the trenches. In my opinion the affection is caused by a micro-organism which has a marked elective action upon fibrous tissue. This theory affords an explanation of the occurrence of myalgia, periostitis or osteo-periostitis, rheumatism, and neuritis as symptoms of the disease. The severe headache which occurs in some cases may be due to a fibrositis localised in the meninges of the brain. Whilst the brain tissue itself is insensitive, the dura mater is richly supplied with nerves, and therefore a fibrositis localised in the meninges would give rise to pain in the head. This was first called attention to, we think, by Dr. Harry Campbell. If we accept this theory as to the cause of the headache in the affection under consideration we can readily explain all its characteristics (worse at night, aggravated by coughing, great intensity in some cases, &c.). I would suggest that the indurative headache of gout is due to a similar morbid condition, although Llewellyn Jones, who has given special attention to the study of the latter subject, thinks that it is due to myositic deposits.

Rosenow, who has recently made extensive investigations in regard to the elective affinity of certain micro-organisms for certain tissues, finds that they undergo mutation on variation of the culture media after successive inoculations into animals, but the factors which determine this localisation are still obscure. His experiments were done by intravenous injection in dogs and rabbits of streptococci isolated from appendicitis, ulceration of stomach and duodenum, cholecystitis, rheumatic fever, erythema nodosum, herpes zoster, epidemic parotitis, myositis and endocarditis. The results showed an elective affinity of these organisms for tissues similar to those from which they had been isolated, those from appendicitis producing lesions in the appendix in 68 per cent., and those from myositis in 75 per cent. of 40 animals, whilst gastric hæmorrhage resulted in a large proportion of those inoculated with cultures obtained from cases of gastric and duodenal ulcer. The gonococcus exhibits a marked affinity for fibrous tissue, Friedländer's bacillus for joints, the tetanus toxin for motor ganglion cells, the diphtheria bacillus for the faucial tonsils, the meningococcus for the meninges, the pneumococcus for the lung, the typhoid bacillus for the lymphatic tissues, the virus of rabies for the central nervous system, that of anterior poliomyelitis for the anterior horns of the spinal cord, the malaria parasite for the red blood corpuscles, and the trichina spiralis for the muscles. By the inoculation of cultures of streptococci (*Streptococcus viridans*) obtained from rheumatic lesions, he

produced typical rheumatic myositis in rabbits. It is interesting to note that in Rosenow's experiments the virulence of some of the organisms was increased by exposure to cold. The fact that the virulence of these organisms is intensified by cold explains the influence of a low temperature in favouring the onset of rheumatic affections. On killing the animals 48 hours after inoculation, many of them showed no other focal lesions than those of the organs in question, and in others the elective lesions were the only severe ones, the rest being insignificant.

Flexner is trying to determine experimentally whether the lesions in the elective tissues are due to the lodgment in them of a larger number of bacteria than in other organs, or whether the bacteria lodged in equal numbers in other organs are capable of surviving only in the elective one. So far the indications point to the former supposition as the correct one, and it appears that the cells of the elective tissue draw the bacteria from the circulation as by a magnet—that is, a process of absorption.

Exposure.—The view that exposure to cold and wet is an important factor in the etiology, together with the fact that the symptoms include, amongst others, pain in the region of joints, ligaments, and muscles, suggests that the morbid condition may be of a rheumatic nature. This hypothesis does not, however, materially add to our knowledge of its genesis, because it is difficult to explain exactly what is meant by the term rheumatism. If we look upon trench shin as a form of rheumatism, the great majority of cases should be classified as that variety of rheumatism which spares the joints but affects the periosteum, ligaments, nerves, and other tissues. This type is sometimes designated "abarticular rheumatism." As examples of abarticular rheumatism we may mention myalgia, rheumatic iritis, rheumatic sciatica, rheumatic polyneuritis, and rheumatic facial neuralgia. Possibly cases of so-called fibrous rheumatism of joints, a condition characterised essentially by morbid changes in the ligaments with little or no change in the interior structure of the joints, may belong to the same category.

The conception of the existence of a pathological condition which may be termed infectious fibrositis is, I think, a useful one in medicine, as it gives a clearer idea of the origin of some diseases which are now recognised as clinical entities, chiefly from the study of their symptomatology. Fibrous tissue is very widely distributed in the body, and may, indeed, be said to form the framework of the body. Moreover, its chemical composition, in common with that of bone, probably does not vary materially with the organ to which it belongs. It is therefore easy to understand that the fibrous tissue in the muscles, nerves, and ligaments will exhibit an elective affinity for the same causative agents of disease as it appears to do in the condition which is now under consideration.

Diagnosis.

In the recognition of the disease the important points are the following: (1) A history of headache and fever in the early stage; (2) the presence of leucocytosis, even in the absence of fever; (3) pain and tenderness on pressure over the tibiæ and tibiales antici muscles; (4) the presence of a neuritis, particularly of the upper extremity; (5) the presence of pain in the ligaments and bony prominences around joints; (6) the greater intensity of the pain in the head, muscles, bones, and joints at night; (7) the prolonged course of the disease, usually from one to three months.

The characteristics of the pain, whether the morbid process be localised in the head, bone, ligament, joint or nerve, are sometimes of value in diagnosis. As already stated, in most cases the pain is worse at night. Some patients state that its intensity is increased by damp weather, others that it is aggravated by the application of heat. A common statement is that it is of a gnawing character, with exacerbations, during which it is "jumping" or "stabbing." Headache and pain in the shins are frequently so severe at night that it is impossible to obtain sleep without the administration of morphine.

Differential Diagnosis.

The symptomatology of trench shin may closely resemble that of trench fever. Indeed, there are some writers who maintain that the two affections are the same. Major T. Houston and Captain J. M. McCloy are two authors who hold this view. They recognise four different types, two described by McNee and Renshaw and two by themselves. They are of the opinion that all the types have the same symptomatology at the beginning, the difference being dependent on the course and duration.

Type 1.—In this type the temperature, which may rise as high as 103° or 104° F. during the first one or two days, tends to fall on or about the third day to normal or even subnormal. It then rises again, and fever may last for six days to a week, after which the temperature falls, with complete relief of the symptoms.

Type 2.—This type is less common, and exhibits the characteristics of relapsing fever. The initial attack lasts about three days, and when the temperature falls the patients feel so well that many of them have been returned to duty. Some days later the symptoms recur, often with a temperature of 103° or 104°. This relapse differs from that seen in the first type of case, in that it is the first of a series. Hunt and McNee state that the average duration of the relapsing type is not less than three or four weeks. In individual cases it may be considerably longer than this. McNee and Renshaw state that they have seen only 20 characteristic cases of this type, but that their experimental results indicate that it may supervene on the basis of the first type, showing that both forms are simply varieties of one and the same disease.

3. Myalgic type.—In the majority of these cases there was no history of previous rheumatism. It differs from the types previously described in that there is only one period of pyrexia, lasting from a few days to a week, whilst the myalgic pains, which are usually limited to the lumbar region and lower limbs, especially the shins, persist after the pyrexia has disappeared, in some cases for several weeks. Pain is worse at night and in cold damp weather.

4. Septicæmic type.—In the septicæmic type the onset is almost always sudden, and fever, without intermissions, persists for as long as from 11 to 30 days. Headache is a most persistent and severe symptom, and there are sometimes definite rigors, nauses, and vomiting. These last symptoms appear to be comparatively rare in the other three forms. After the temperature has fallen to normal recovery is usually rapid, there being no recurrence of the pains.

According to the above classification the affection which forms the subject of this paper would be of the myalgic type. I am not convinced that the classification of Major Houston and Captain McCloy is correct. The important symptoms of trench shin, in addition to the fever and leucocytosis, are headache and other symptoms which might be called rheumatic. The parts involved have been referred to in discussing the symptomatology. In trench fever headache and pain in various parts may be present, but in the great majority of cases these symptoms are not outstanding and are only present during the febrile stage. In some cases, however, pain in the shins may be present for two or three weeks, but this pain is not usually intense. Moreover, headache and soreness or pain in the back and other parts are common manifestations in the febrile stage of many morbid conditions. The difference between the origin of these symptoms and the origin of the manifestations of trench shin is dependent upon the difference in the affinities of the bacteria for fibrous tissue.

Prognosis and Treatment.

The course of the disease is very slow, but, as will be seen later, it varies considerably in individual cases. Recovery eventually takes place, however, after a period of two or three weeks to two or three months. As far as we know, there are no sequelæ. The best guide to progress in recovery is the intensity of pain, and if it gradually diminishes from day to day recovery may be expected in from two to three weeks. The leucocyte count also sometimes gives valuable indications in regard to prognosis, as recovery within a short time may be looked for if it is within normal limits.

The treatment is chiefly preventive. It is obvious that one of the first essentials is the avoidance of anything, such as tight boots or puttees, which is likely to obstruct circulation. Lorrain Smith, Ritchie and Dawson suggest the advisability of substituting moleskin leggings for puttees. These provide the protection of an ample cushion of air and drain more readily than puttees, thus minimising the loss of heat. Delépine suggests waterproof bags made of oiled silk, similar in shape to fishing-boots. The outer sock, which should be sufficiently large to draw over the oilskin, should be made of material which is not liable to shrink when wet.

In a book describing the preventive measures which were found most effective in the winter campaign of the Japanese Army in Manchuria it is recommended that the feet, legs,

and, if necessary, the whole of the body, should be thoroughly rubbed with animal fat or animal oil. In order to obtain the maximum effect the oil should be of high boiling-point and used in considerable quantity. Daily massage of the parts between periods of trench duty has also been recommended. A similar preventive measure has been much used in the present war—that is, applying vaseline or whale-oil liberally to the feet and legs.

In the curative treatment measures for treatment of an infectious disease are indicated. Rest in bed is essential. Acetyl-salicylic acid and phenacetin may be tried for the relief of pain, but it is often necessary to give morphia. In cases in which the pain in the tibiæ has been very severe an incision through the periosteum has sometimes been made, and is said to be of much value.

McNee and Renshaw, on the assumption that antibodies to the infected virus might develop in the course of spontaneous cure, removed 20 c.c. of blood from a patient 10 or 12 days after his last relapse, and four hours later injected the serum into the veins of two who were just beginning to relapse. It appeared to have no influence whatever on the course of the disease.

Illustrative Cases.

CASE 1.—Private H. The patient had been formerly a coal-miner, and had been in the service for one and a half years. His habits had been temperate and his previous health very good. He was admitted to No. 4 Canadian General Hospital, Salonica, on Jan. 27th, 1916. He stated that his illness commenced three days before admission, the first symptoms being headache and pain in the shins. He attributed the pain in the shins to exposure and a march of 19 miles. On the march he wore puttees, but they were not tight.

Present condition.—The patient complains of pain and a burning sensation in the shins, the dorsal surface of the feet, and the central portions of the tibiales antici, the pain being more severe at night and in wet weather. At night it is continuous, with exacerbations every few seconds, during which it is stabbing in character. There is pain on extension of the foot. The parts previously referred to are painful on deep pressure. Reflexes normal and active. No disturbance of epicritic sensation. Urine normal. White blood corpuscles 19,000.

CASE 2.—Sergeant-Bugler M. The patient, aged 28, had suffered from rheumatic fever at the age of 10 years. He had been in South Africa for two years and in India for seven years, and during these nine years had had three attacks of fever. He stated that aching pains in the leg had been fairly constant during the last month. His general health had been fairly good, but he felt weak and his appetite had been poor. His throat had not been sore, and his teeth were in good condition. There was no gastro-intestinal disturbance. During the last three weeks he had been in the hospital, but the pain had not been relieved.

Present condition.—On examination the heart, lungs, and urine were found to be normal. White blood corpuscles 22,000. Temperature normal. Soreness and pain are limited to the inner surfaces of the tibiæ and the dorsal surfaces of the feet. The tibiales antici are not involved. Both flexion and extension are more painful than normal. Reflexes normal.

CASE 3.—Sergeant B., admitted to No. 4 Canadian General Hospital on Jan. 25th, 1916. He stated that about the middle of last December he began to suffer from headache and pain in the back and thighs, especially on rising in the morning. It usually subsided after he had been moving about for a while. On Jan. 1st the pains had seemed to leave the back and thighs and become localised in the shins and front and side of the knees. There was also slight pain in the elbows.

Present condition.—Pain in shins and at the side of the knees over the tuberosities of the femur. It was of a dull throbbing character and was worse at night. White blood corpuscles 8000.

CASE 4.—Sergeant W., aged 31, admitted to No. 4 Canadian General Hospital, Salonica, on Jan. 24th, 1916. The illness commenced on Jan. 16th with fever, headache, and pain over the shins, which continued for four days, being worse at night. The headache lasted three days. When taken ill the patient was working at headquarters and had had no marching or exposure since December, when he was in Serbia.

Present condition.—There is marked tenderness over the bellies of the tibiales antici on both sides, and slight tenderness over the crests of the tibiæ, together with occasional pain in the knees. Dorsiflexion of the foot is painful. Pain is relieved by the application of heat. White blood corpuscles 16,000. Examination otherwise negative.

CASE 5.—Private W., aged 26. Two months previously, while in Egypt, he had found that he was unable to march owing to pain and stiffness in the legs. There was no fever. He had not been in the trenches or exposed to cold. During his previous seven months in France he had had no trouble.

Present condition.—On admission to No. 4 Canadian General Hospital on Jan. 26th complained of pain in the knees and shins. There was marked tenderness over the tibiales antici on both sides, especially above the ankles along the course of the tendon, and slight tenderness over the internal surfaces and crests of the tibiæ. The pain was worse at night, and not relieved by heat. Dorsiflexion of the foot painful. No fever. White blood corpuscles 14,000. Examination otherwise negative. On Feb. 5th the white blood corpuscles numbered 13,500. Pain still severe, the slight tenderness over the tibiæ remaining as before.

CASE 6.—Private L., aged 34, admitted to No. 4 Canadian General Hospital on Jan. 24th, 1916. Ten days previously, whilst on guard, he began to suffer from headache and pain in the front of the legs. It came on quite suddenly. He had been trench digging both in France and Salonica, but had not recently been exposed much to either cold or wet.

Present condition.—There is tenderness over the internal surfaces and the crests of the tibiæ. The tibiales antici are tender on pressure. Pain is worse at night and increased by heat. There is a callous area over each instep. Temperature 101·4° F. White blood corpuscles 12,000. On Feb. 1st marked pain and tenderness over internal surface of the tibiæ, in bellies of tibiales antici on both sides; worse at night. Since admission the temperature has been irregular, going up to 100° F. White blood corpuscles 10,000. Examination otherwise negative.

CASE 7.—Lance-Sergeant B., aged 24, had enlisted in Toronto on May 28th, 1915. In England Dec. 1st, 1915. In France Feb. 20th, 1916. Had an attack of *la grippe* about the end of February, 1916. The present illness began during the first week of June with headache, pains in the joints and muscles, and fever. The headache was aggravated by coughing and was worse at night. The patient was sent to a field hospital, where he remained for nine or ten days. Whilst there the temperature was normal or subnormal in the morning and slightly elevated at night. He returned to duty, but was unable to carry on. He was sent to hospital, Boulogne, and from thence, on June 30th, to the Ontario Military Hospital, Orpington.

Present condition.—Complained of weakness, of loss of appetite, and of pains in shoulders, elbows, wrists, knees, and ankles. Three days later—i.e., July 3rd—pain experienced in shins, which gradually became worse, and at the same time the pain in the joints became less severe. In about a fortnight the pain in the joints subsided. That in the shin bones was worse at night and seemed aggravated by dampness. Relief for an hour or two was sometimes obtained by taking 10 grains of acetyl-salicylic acid. The pain was of a gnawing character and was localised in the middle third of the tibiæ. The surfaces of the bones were sensitive and tender on pressure. Since admission the temperature had been normal or subnormal. On August 13th white blood corpuscles, 15,400; polymorphonuclears, 65 per cent.; lymphocytes, large and small, 31 per cent.; eosinophiles, 4 per cent. On the 25th the patient complained of a dull pain and tenderness on pressure at the back of the right shoulder, at about the level of the sixth or seventh cervical vertebra. On the 28th there was still pain at the back of the right shoulder. There was also pain along the posterior part of the internal surfaces of the arm, extending along the ulnar side of the forearm into the little finger and the adjacent half of the ring finger. The ulnar nerve was sensitive to pressure at the elbow. No material weakness of muscles supplied by ulnar nerve. Electrical reactions normal. Hyperæsthesia of little finger and adjacent half of ring finger. Pain at back of right shoulder produced by raising the right arm from the side. Slight pain in shin bones. On Sept. 9th the pain had almost gone from the shins, and that in the right arm had lessened. On Oct. 3rd the patient was free from pain and his general condition was fair.

The interesting points of this case are: (1) During the first two or three weeks of the illness the pain was chiefly limited to the joints; (2) the tibiæ became involved during the third week; (3) the ulnar nerve became involved during the eighth or ninth week; (4) the comparatively high leucocyte count in the absence of fever.

CASE 8.—Sergeant B., aged 43. Service 23 months. Health before enlistment good. On July 7th had been operated upon for piles at Dannes Camiers, and subsequently made a good recovery. About three or four weeks later the present illness began with pain at the back of the neck and left shoulder, the temperature being elevated. Three days later pain in shins and forearms. On August 12th transferred to Ontario Military Hospital, Orpington.

Present condition.—August 13th: Complaint: Pain in shins, forearms, and in a small area near the seventh cervical vertebra at the back of the left shoulder. Much worse at night. Pain in shins continues and of a gnawing character, with exacerbations, during which it radiates to the thighs and feet and is equally severe in both legs. The posterior and internal surfaces and crests are slightly sensitive. Pain and tenderness in the tibiæ are limited to the middle thirds of the bones. In the forearms there is little pain, but there is tenderness on pressure for about 5 inches above the wrist in a longitudinal line between the radius and ulna and at the back of the left shoulder just to the left of the seventh cervical vertebra. Raising the left arm from the side causes pain in the back of the left shoulder-joint. Temperature slightly elevated. White blood corpuscles, 15,500. The differential count gave the following percentages: polymorphonuclears, 75; small mononuclears, 15; large mononuclears, 6·5; basophiles, 1·5; eosinophiles, 1·5; transitional, 0·5. Sept. 2nd: Very little pain in shins. Area at back of shoulder and forearm still tender. Temperature has been normal for six days. 5th: Improved; very little pain, and only slight tenderness in areas mentioned above. Oct. 18th: Pain completely gone.

In this case, although the pain at the back of the left shoulder was similar to that of Case 7, there was no pain along the course of the ulnar nerve.

CASE 9.—R. H. L., aged 33, had enlisted in February, 1915, and was sent to France in February, 1916. The present illness commenced on Sept. 2nd, 1916, with headache, pain in arms, legs, and back, all these symptoms being worse at night. Slight fever during the first three days. The patient was sent to a clearing station, and thence to a hospital in Boulogne, and ten days later to the Ontario Military Hospital, Orpington.

Present condition.—Complaint: Pain in shins, back, thighs, biceps, and in tibiales antici. Worse at night, and all the painful areas tender on pressure. On coughing pain felt at the back of the head. White blood corpuscles 11,000.

CASE 10.—E. J. K., aged 49. Service nine months. Enlisted February, 1916, and was sent to France the following month. Health good until August 25th, when he began to suffer from pain in the left knee. Five days later pain was felt behind the left shoulder and a sensation of "pins and needles," as well as pain in the little and ring fingers of the left hand. He paraded sick, and was sent down the line to Boulogne, and thence two days later to Ontario Military Hospital, Orpington.

Present condition.—Sept. 3rd: Complaint: Pain and sensation of "pins and needles" in little and ring fingers of left hand, in ulnar side of left forearm, in the back of the left shoulder and left side of the neck, and slight pain in the left knee-joint. All the painful areas sensitive to pressure. The "grip" of the left hand weak. The muscles supplied by the ulnar nerve react to the faradic current. 10th: No pain in left knee. Condition of left arm remains about the

same. White blood corpuscles 10,400. Oct. 1st: Less pain in left arm. Nov. 1st: Strength of left hand improved. Coughing causes severe pain in left side of chest. Nov. 21st: Slight pain in ulnar side of arm. Pain on left side of chest on coughing. Dec. 1st: Patient still complains of slight pain in hand, left shoulder, and along ulnar side of left arm.

In this case the special localisations of the morbid process were probably limited to nerve and ligament.

CASE 11.—Private L. Patient enlisted in September, 1914, and was sent to France in August, 1916. In November, 1916, he reported ill on account of loss of power in right forearm and fingers. He suffered no pain except headache at the beginning of his illness. Immediately prior to becoming ill he had been exposed in the trenches to cold and wet, and one week after the beginning of his illness pain began in the shins. This lasted about ten days. Admitted to Ontario Military Hospital Dec. 3rd, 1916.

Present condition.—Patient unable to extend the right wrist (wrist-drop). Flexion and extension of right elbow-joint present, but on forced flexion at this joint the supinator longus does not contract. Inability to extend the proximal phalanges of the fingers. Over the back of the thumb and the radial side of the hand is an area of partial anæsthesia. Extensor muscles of hand and supinator longus react to faradic current, but the contraction to galvanic stimulation is changed. A.C.C. greater than K.C.C. Heart, lungs, and abdominal organs normal. White blood corpuscles, 10,600; polymorphonuclears, 53 per cent.; lymphocytes, 47 per cent. Jan. 24th: Patient very much improved. Can extend the hand slightly. Feb. 8th: Recovery.

This case was sent as one of musculo-spiral paralysis of unknown origin. From the clinical history I should judge that it may be classed with trench shin.

AMŒBIC DYSENTERY AND ITS RELATIONSHIP TO A FORM OF DIARRHŒA OCCURRING IN EGYPT.

BY G. MARSHALL FINDLAY, M.B., CH.B. EDIN.,
TEMPORARY SURGEON, ROYAL NAVY.

DURING the past year the opportunity has been given me of studying the illnesses among naval ratings during the first few months of their residence in Egypt. Diarrhœa and amœbic dysentery have been by far the commonest causes of ill-health, and I am here suggesting a relationship between these two conditions.

Diarrhœa with Gastric Symptoms.

Of the Europeans who arrive in Egypt for the first time, it is probable that nearly 90 per cent. suffer from a form of diarrhœa, associated with gastric symptoms, which is so common that it is known among Anglo-Egyptians as "Egyptian stomach." The first attack usually comes on within a fortnight of arrival in the country, while subsequent attacks may recur at intervals of from one to two weeks. After a residence of roughly six months the disease entirely subsides and does not again appear. Owing to the comparatively slight symptoms the condition has failed to attract any very great notice among specialists in tropical medicine.

A typical attack usually begins in the early hours of the morning, although it may commence at any hour of the day or night. At first there is only slight abdominal uneasiness, but this is quickly followed by definite griping pains, confined for the most part to the epigastric and umbilical regions. There is a marked desire to empty the bowels, though evacuation gives little relief. As many as 10 or 15 stools may be passed during the day. Nausea and vomiting are present in about three-quarters of the cases, while in a few instances headache is a marked symptom. The temperature is slightly raised in the evening —98·8° to 99·8° F., while the posterior part of the tongue is covered with a brownish fur. The diarrhœa does not persist for more than two or three days at the outside; it is usually followed by constipation. About a week generally elapses before the bowels regain their normal action. A similar attack may recur within a fortnight or three weeks of the original attack. The fæces are always fluid in character and in a typical case resemble pea-soup; blood and mucus are absent. The blood shows no definite changes, except a slight but constant increase in the large mononuclear leucocytes (10–18 per cent.).

The condition is not confined to any particular class; officers and men, whether living ashore or afloat, are equally affected. It has no relationship to the presence of sand-storms, which in this country are confined to the early spring months. Dietetic errors are hardly likely to be responsible for so prevalent a condition. There appears, however, some ground for considering the disease to be of an infective character. Thus, of 120 sailors arriving in Egypt in March, 1916, 30 had reported sick with the condition by the end of July, while a further 50, on questioning, confessed to having had attacks of diarrhœa and gastritis, though they had not deemed the occurrence worth reporting. Since August these men have been entirely free from this condition, though they have not been exempt from attacks of amœbic dysentery. As a general rule, the diarrhœa and gastritis are more severe in persons under 20 and over 40 years of age.

Amœbic Dysentery.

The second most important cause of sickness among naval ratings has been amœbic dysentery. Cases of this condition can be separated into two classes: (1) Old dysenterics who have relapsed; (2) first attacks in persons who have never before been abroad. In the present series of cases the former class constitute nearly 20 per cent. of the total number, and as in the majority of instances the dysentery was first contracted in Gallipoli, during the Dardanelles campaign, since then these cases must have been acting as "convalescent carriers." Doubtless an examination of the stools of everyone in Egypt, if such a thing were possible, would reveal the presence of a very large number of carriers of this description.

For the most part, the cases all conformed to the classical type of a mild amœbic dysentery, with blood and mucus in the stools. The clinical symptoms were headache, lassitude, slight abdominal pain, and diarrhœa, with some tenesmus. The temperature was slightly elevated, but rarely exceeded 100°. On microscopical examination *Entamœba histolytica* was found to be present in the stools in every instance, though, as is so common in this form of dysentery, the excretion of entamœbæ was of an intermittent character.

Apart, therefore, from the condition of the stools, the clinical symptoms were very similar to those described as occurring in the condition known as "Egyptian stomach." In the case of first attacks of dysentery, the dysenteric symptoms do not as a rule manifest themselves until the patient has been resident in the country for a few weeks at least. In one instance, however, a sailor, 18 years of age, developed a typical attack of amœbic dysentery two days after arrival in Egypt. The patient stated that he had never before been abroad, but two years previously had had an attack of dysenteric-like symptoms. Inquiry, however, showed that both the boy's father and brother were in the Army; the former had returned from India shortly before the patient's first attack. This, therefore, appears to have been an autochthonous case occurring in England. An attack of dysentery may, however, manifest itself after a residence of some months or even years, but in many cases there appears to have been a previous history of "Egyptian stomach." Thus inquiry into 40 cases of dysentery occurring for the first time elicited that in 36 instances there was a previous history of one or more attacks of "Egyptian stomach," preceding the onset of dysenteric symptoms. The intervals elapsing between the last attack of "Egyptian stomach" and the commencement of the dysentery varied from a few days to some months.

Relationship of the Two Affections

In order to determine whether there was any relationship between the two conditions a microscopical examination of the fæces was carried out in 110 cases of "Egyptian stomach." In regard to the presence of entamœbæ, the following results were obtained:—

Entamœbæ entirely absent	8	cases.
Entamœba coli present	10	,,
Entamœba histolytica	36	,,
Entamœba minuta (Elmassian)	49	,,
Entamœba minuta (Elmassian), together with tetragena cysts	7	,,

A method of vital staining was employed, neutral red being used in a dilution of 1 in 10,000, as recommended by Rogers.[1] By this means the entamœbæ are coloured a rose pink, while the background remains unstained.

An analysis of the above figures shows that in 43 instances the causal agent of amœbic dysentery—*Entamœba histolytica*—was isolated from the stools. It was present either in the vegetative form (36 cases) or in the encysted stage (7 cases). It has been recently pointed out that this latter stage may occur, not only in chronic, but in very mild cases of dysentery.[2]

In 56 instances there was present, either alone (49 cases) or in conjunction with tetragena cysts (7 cases), an organism which was probably *Entamœba minuta*. This variety was first described by Elmassian as occurring in soft diarrhœal stools.[3] It has lately been found to be much more common than was formerly supposed,[4] while the majority of authorities are now agreed that it is merely a stage in the developmental cycle of *Ent. histolytica*, probably a precystic trophozoite stage.[5] The minuta variety resembles *Ent. coli* in size, but differs from it slightly in appearance. Not infrequently the endoplasm contains a few red blood corpuscles. The only definite means of differentiating between *Ent. coli* and *Ent. minuta* lies in inoculation experiments. In the present instance these unfortunately could not be performed. There is, however, presumptive evidence to prove that in the cases above referred to the organism present was *Ent. minuta* and not *Ent coli*.

When I first studied "Egyptian stomach" I treated the condition as one of simple diarrhœa. Bismuth and opium were prescribed with excellent results so far as the relief of the immediate symptoms was concerned. Within a month, however, eight of the patients so treated developed classical attacks of amœbic dysentery, *Ent. histolytica* being isolated from the stools. Since that date all cases of "Egyptian stomach" which have come under me have been treated with a course of emetine injections, with the result that only one of the patients so treated has subsequently developed amœbic dysentery.

To summarise the results, it may be said that of 110 cases 43 showed the presence of *Ent. histolytica* either in the vegetative or encysted form, while in 49 there was some evidence to prove its presence in the minuta form.

In those countries where it is endemic, amœbic dysentery is of very common occurrence, a fact which is illustrated by the large amount of original work that has emanated from Egypt and India on the subject. Although no figures are available as to the number of carrier cases in these two countries, it must be very considerable. In the case of Tonkin it has been found that no fewer than 8 per cent. of the population are dysentery carriers.[6]

It has long been recognised that every person is at some time or another exposed to infection from tubercle bacilli; in exactly the same way it is probable that in a country such as Egypt everyone is sooner or later exposed to entamœbic infection. Not only is there a vast army of carriers among the general population, but the agents of dissemination in the shape of flies are also constantly present. It would, however, appear that in the majority of individuals the entamœbæ are rapidly removed from the system.

The presence of active amœboid forms in the intestine is correlated in the first instance with certain clinical symptoms—the condition known as "Egyptian stomach." As the vegetative activity of the entamœbæ disappears, the acute symptoms also decrease, while the cysts which are then formed may either be destroyed in the intestine or else continue to be passed in the process of defæcation. The clinical symptom "diarrhœa" is in reality a protective mechanism, whereby the organism seeks to rid itself of deleterious matter in the intestine. The fatigue and a consequent lowering of the resistance caused by excessive evacuation are only secondary effects. In some individuals, the entamœbæ, as has been said before, continue to flourish, without, however, giving rise to any symptoms, until such time as the general resistance becomes lowered, when an attack of dysentery may supervene.

Before the war amœbic dysentery was comparatively rarely met with in the British Isles; with the cessation of hostilities and the return from hot climates of large bodies of men it is probable that the disease will become much more common, unless measures are taken to detect and effectively treat all carrier cases. This, however, is a work of the very greatest difficulty. It is therefore essential to prevent, by all possible means, the formation of such carriers. One of the methods to be employed in this connexion should be the treatment of all suspicious conditions, such as "Egyptian stomach," with what is practically the only specific for amœbic dysentery—namely, emetine.

THE TREATMENT OF GONORRHŒA IN A FIELD AMBULANCE.

BY E. T. BURKE, M.B., CH.B. GLASG.,
LIEUTENANT-COLONEL, R.A.M.C. (S.R.)

THE essential equipment of a field ambulance is for the reception and treatment of casualties occurring in the field. The scale of equipment shows that it has never been contemplated that such a unit will ever be called upon to treat cases of gonorrhœa. Theoretically no man is allowed to proceed on active service while suffering from venereal disease, and (also theoretically) he is not able to acquire it while in the field. In practice this theory often breaks down, and a case of gonorrhœa or syphilis may, and often does, fall to be treated in a field ambulance. Such a case may have to remain in the ambulance for weeks before it can be transferred to a hospital which is equipped with the proper means for administering treatment. For example, when the transport, carrying some 3000 troops, on which the field ambulance to which I belong had been two days at sea, *en route* for the Dardanelles, five men were admitted to the troops' hospital suffering from acute gonorrhœa. These were evidently new first infections, and at the medical inspection of troops prior to embarkation had presented no symptoms, thus escaping detection by the regimental medical officers. As a field ambulance was on board, to it fell the medical care of the troops, and as these cases of gonorrhœa were handed over to me I was presented with the problem as to how they were to be treated efficiently and rendered fit to return to full duty in the shortest possible time with the slight means of treatment at our disposal.

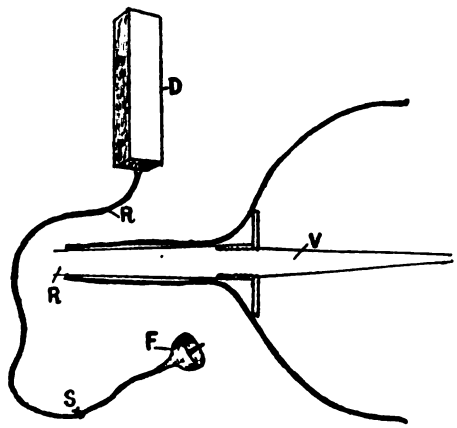
It is of very vital importance that cases of gonorrhœa occurring in soldiers, and especially in those proceeding on active service or actually in the field, should be brought under treatment immediately and efficiently, that they should be cured quickly, and that the cure should be a permanent one. To the "slacker" a chronic gleet is a heaven-sent gift to enable him to report sick and so evade his duty. A certain type of soldier—happily not a common one—will retain a gleet and take admirable precautions against it being cured, so that he can produce it on sick parade the very moment that he knows there is any hard work in front of his battalion. The penalties for the concealment of venereal disease do not act as a deterrent. The loss of efficiency when an acute gonorrhœa is allowed to lapse into the chronic state is very great indeed.

Consideration of Methods of Treatment.

A rapid, efficient, and permanent cure was the object aimed at in the five above-mentioned cases. The four following methods of treatment suggested themselves: (1) Drugs—e.g., copaiba, &c.; (2) injections with a syringe; (3) a combination of (1) and (2); or (4) Janet's method of pressure irrigation or "lavage." The first three methods were discarded because they are unscientific, inefficient, and dangerous.

Drugs are slow in their action, extremely uncertain, and create digestive disturbances, rashes, &c. They are the stock-in-trade of the venereal-treating chemist and the quack; and in a proportion of the cases where they are prescribed by a medical man they are simply a salve to the conscience of a lazy practitioner. I have known many instances where an untreated gonorrhœa—in men on board sailing ships, for example—has progressed just as favourably

as one which has been treated by the swallowing of copaiba, sandal-wood oil, methylene blue, and so on.



The use of a syringe, whether in the hands of a surgeon or of the patient, is fraught with danger. To cause a patient with an acute gonorrhœa to first empty his bladder and then to force a jet of silver nitrate or some such solution against his compressor urethræ muscle too often results in some infection being forced back behind the compressor into the posterior urethra or bladder. A certain period of time elapses before the patient collects enough urine to again micturate and wash out the injection, and during this time the gonococci have had the chance of implanting themselves in virgin soil, and the common sequelæ—posterior urethritis, epididymitis, and cystitis—result. Further, in gonorrhœa micturition takes place before sufficient urine has collected to properly wash out the infective material and a certain amount of it remains. A syringe, even in the hands of the surgeon, is unsafe; in the hands of the patient it is dangerous. Too often the patient, having been taught by the surgeon to use a syringe, decides that he can do it as well as the surgeon. He decides to save the surgeon's time and his own money, so, armed with a syringe and an injection solution, he solemnly washes the infection into his bladder. The syringe is bad treatment and the sooner it is relegated to the museums as a relic of the dark ages of urology the better.

No matter how careful one may be, one is always in danger of overcoming the resistance of the compressor urethræ muscle, forcing back some gonococcal material and extending and complicating an originally simple disease. There is present, but in a lesser degree perhaps, the same danger in cases which are treated by drugs internally. The painful erections to which these patients are subject frequently cause slight relaxation of the compressor and backward extension of the disease.

Adherence to the first three methods enumerated causes the complications of gonorrhœa which are, unfortunately and unnecessarily, so familiar; and when complications occur in a case of simple gonorrhœa it is a proof that the treatment is bad or inefficient. No case of anterior urethritis (and all gonorrhœas are at first confined to the anterior urethra) coming under treatment before backward extension has taken place should ever have any complications or sequelæ. The disease begins anteriorly; it should continue anteriorly. It should finish in the same place, and "leave not a wrack behind." By proper use of the Janet method this can be done; improvement is rapid, the relief of symptoms is almost immediate, and the cure is permanent.

The Method Adopted.

Holding these opinions, I was forced to extemporise a much modified Janet's lavage apparatus, as is shown in

Sketch of extemporised Janet's lavage apparatus, with a longitudinal section on a larger scale through the filter funnel showing the nozzle in position. D, douche-can; R, rubber tubing; F, filter funnel; V, vulcanite nozzle; S, stopcock.

the illustration. It was composed of a douche-can with a holding capacity of four pints. This was procured from No. 1 Field Surgical Pannier. Two separate 3-ft. lengths of rubber tubing were also culled from the same source. These were joined together by a vulcanite stopcock. One end of the tubing was fixed to the outlet of the reservoir; the other end was threaded through the stem of an enamelled-iron filter funnel and finally finished off with a vulcanite enema-syringe nozzle, as is shown. The object of the filter funnel is, as in Janet's apparatus, to catch any backwash from the urethra and to protect the surgeon from being splashed with the returning solution. The solution used was potassium permanganate. No definite strength was adhered to, as the urethra gradually acquires a toleration to potassium permanganate. On the first day irrigation was commenced with the solution of a faint pink colour, and this was gradually increased in strength each day.

The theory of the treatment is briefly this. It is to be recognised that the great danger in all local treatment of gonorrhœa is of infective material being carried past the barrier of the compressor urethræ *and being left there*. This danger is realised as being inevitable, and so means are taken to wash out the whole urinary canal from the bladder to the meatus, and thus to ensure that every vestige of infective material is carried away. At the same time, the lavage solution is of such a nature as to render innocuous any slight amount of the organisms which may be present.

The method is as follows. The patient having micturated (thus flushing out the urethra), he is placed lying on his back on a table, with his legs apart and his thighs slightly flexed. Between his thighs is placed a basin to catch any back-flow of solution from the urethra. The glans and prepuce are thoroughly cleansed, the douche-can is raised about 2 ft. above the patient's pelvis, an assistant turns on the stopcock, and a gentle stream of the irrigating solution is allowed to flow. The temperature of the solution is 104° F. The surgeon then inserts the nozzle, while the stream is flowing, into the urinary meatus, and the anterior urethra is thoroughly washed out. An elevation of 2 ft. of the reservoir above the patient's pelvis is not sufficient to overcome the resistance of the normal compressor. The irrigation stream is kept at a steady flow, and by alternately inserting and withdrawing the nozzle from the meatus the anterior part of the urethra is thoroughly flushed with fresh solution. The back-flow is caught by the protective shield of the filter funnel and collected in the basin between the thighs of the patient. The elevation of from 2 to 3 ft. is, while not overcoming the compressor, sufficient to cause a dilatation of the anterior urethra, to open up the crypts and lacunæ, and to bathe them in permanganate solution, thus bringing every part of the urinary canal under the influence of the irrigating solution. If the disease is confined to the anterior urethra that ought to be sufficient. This is all that is done by the syringe method. Theoretically the syringe method stops there. But when it is realised that in spite of all care infection may exist in the posterior urethra, or that while washing out the anterior part the compressor may, as it often does unknown to the patient or surgeon, relax momentarily and allow some infection to pass backwards, then it becomes one's duty to take measures to counteract such a happening and to prevent its consequences. The point to realise is that there is no means of absolutely preventing relaxation of the compressor, therefore one has to suppose that in every case relaxation has taken place, and that it behoves one to take appropriate measures to prevent any damage. The reservoir is now raised to a height of 5 or 6 ft. and the stopcock is opened to its fullest extent. Experience has shown that this elevation is normally sufficient to overcome the compressor. The patient should be instructed to breathe easily and to attempt the act of micturition, thus relaxing the compressor, and the solution will be found to run into the bladder.

Occasionally one experiences a little difficulty in overcoming the compressor. This is usually due to nervousness on the part of the patient. If he is engaged in conversation and his mind is taken off contemplating the novel experience he is undergoing, it will often be found that the compressor is "caught napping" and that the solution will run in. In other cases it may be necessary to "dodge the compressor" by projecting alternately vigorous and weak jets of the solution against it. The assistant can do this by regulating the opening of the stopcock. If the patient has the rationale of the proceedings explained to him, he overcomes his nervousness, takes an intelligent interest in the matter, and can help materially in filling his own bladder. Once the barrier has been overcome the force and pressure of the stream keep the urethral canal patent.

In the most difficult case, uncomplicated by an old stricture, perseverance will always succeed, in spite of the belief

prevalent in many minds that the bladder can only be filled by means of a catheter. The truth is that with a little experience any normal bladder which is guarded by a normal urethra—i.e., one which is free from greatly abnormal narrowing—can be filled by the above method.

By means of percussion and by heeding the patient's sensations one can tell when the bladder is full. When this stage is reached the stopcock is closed, and by compressing the meatus of the urethra with the fingers all the fluid is retained in the urinary passages. The bladder and urethra are now fully dilated by the pressure of the solution; every recess and crevice is bathed in it, and every focus of infection is opened up and subjected to its action. If after the lavage of the anterior urethra any gonococci have been carried back to the bladder, they are now floating, well diluted, in a vast ocean of bactericidal solution. After allowing the solution to remain in the urethra and bladder for 20 or 30 seconds the meatus urinarius is released, and the anterior urethra empties itself. The patient now sits up, and by the act of micturition empties his bladder of the permanganate solution into a basin. The solution usually returns slightly reduced at first. The whole procedure is repeated several times till the permanganate returns unchanged.

It will be found that the first attempt to fill the bladder is the most difficult, but that as soon as the patient overcomes his nervousness and realises what is required of him it becomes perfectly simple. Some patients rapidly learn to do the lavage themselves and carry through the whole treatment in a perfectly easy and skilful manner.

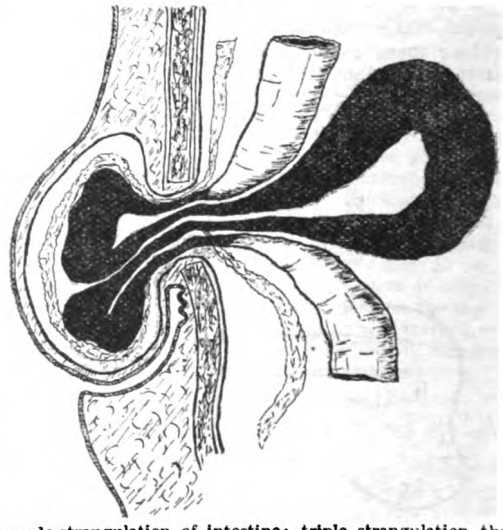
Results of Treatment.

The treatment of the five cases mentioned was followed in accordance with the above principles. Lavage was carried out three times daily for the first three days at 9 A.M., 2 P.M., and 9 P.M. The patients were put on light diet and forbidden alcohol or condiments, but smoking was not restricted. They were given no drugs internally, but were ordered to drink as much water as they could. This excellent diuretic kept the urine bland and non-irritating. On the second day of treatment they reported that they had no pain on micturition, and the discharge, which had been copious and creamy 24 hours before, was thin and small in quantity. On the third day all use for gonorrhœa bags had ceased as the discharge was negligible. From the third to the tenth day they were irrigated twice daily, morning and evening. On the eighth day, in one of the cases, the discharge was completely stopped and he had no other symptoms. He was put on full diet and beer. Next morning he had a slight discharge, so he was returned to treatment. On the tenth day Malta was reached, and the cases now who exhibited no symptoms whatever went sent ashore to hospital, so that a microscopic examination of smears from their urethras could be made as to the presence or absence of the gonococcus, which is the only real test of cure. The "two-glass" test, which was done before they were sent ashore, showed no turbidity in either of the glasses, except in the first glass of the patient who had been put on full diet and beer. In his case there were a few flakes present. The transport left Malta the same day, so that the cases were lost sight of.

The conclusions which present themselves may be summarised as follows. That treatment by the Janet method, as described above, is more successful in rapidity of disappearance of symptoms than any other; that in civil practice experience has shown that the gonococcus can be cleared from the urethra in three weeks by this method; and that there are no sequelæ. These things are perhaps even more important in soldiers on active service than in civil life; and even with the modified and extemporised apparatus used as described the results were almost perfect. Lastly, it is not beyond the resources of a field ambulance on active service to treat efficiently and cure cases of acute gonorrhœa by the method of lavage.

THE HEALTH OF SCHOOL CHILDREN IN DEVONSHIRE.—The medical officer of health for the county of Devon in his annual report states that between 35 and 40 per cent. of the boys leaving the schools under the Devon education committee were under the normal weight. He adds that the boys suffered from insufficient food and rest, and that insanitary conditions existed in the schools and their homes.

RETROGRADE STRANGULATION OF THE INTESTINE FROM CONSTRICTION BY AN EXTERNAL APERTURE.



BY SPENCER MORT, CH.B., M.D. GLASG., F.R.C.S. EDIN., F.R.S. EDIN.,
LIEUTENANT-COLONEL, R.A.M.C., COMMANDING EDMONTON MILITARY HOSPITAL.

MADYL'S hernia is a type in which the intestine descends into the sac in a W fashion, thus there are two external loops united by a third, which remains for the most part in the abdomen. Similar cases have been described by Peyrot, Lauenstein, Macewen, Pringle, Laroyenne, and others. In the event of strangulation three loops may be involved. In the case described by Laroyenne,[1] and reported[2] and translated by me, the following was the condition:—

The patient, aged 60, suffered for a long time with a reducible hernia about the size of two fists, which passed from the right inguinal canal into the scrotum. The evening before the operation the hernia became irreducible and signs of complete strangulation of the bowel came on suddenly without distension of the abdomen. At operation next day the sac was opened and abundant lemon-yellow serous fluid escaped. Two loops of bowel presented inside the sac—a portion of the cæcum with the terminal part of the ileum and a loop of small intestine. Both looked healthy without any appearance of ecchymosis or sloughing and the constriction was sufficiently loose to allow them to be drawn down easily for examination of the neck of the protrusion. This manœuvre revealed a third coil of small intestine, joining the two in the hernia, and passing upwards into the abdominal cavity. This portion was completely strangulated, black in colour, and studded with greenish spots of commencing gangrene, an appearance extending far up in the coil. Laparotomy was then done, and the attachment of this loop to the two portions of the bowel in the sac was confirmed. Some bloody fluid with a fœtid odour was found in the peritoneal cavity, but resection was deferred on account of the collapsed state of the patient and the great extent of damaged intestine. The wound was left open, with drainage of the abdomen in the region of the dead gut, but during the night the patient succumbed. An autopsy was made, at which it was found that over six feet of the bowel was destroyed by strangulation. No other abdominal lesions were found.

In résumé, the author considers that the immunity of the cæcum is due to the thickness of its walls. As to the reason for damage to the intra-abdominal small intestine, with escape of the protruding small intestine, he believes that torsion on its axis probably occurred. Such was not noted post mortem, but the conception is favoured by the great length of the bowel, pedunculated in a sense at the internal ring.

FIG. 1.

Retrograde strangulation of intestine; triple strangulation through one aperture. The omentum is seen passing into the sac which is above the umbilicus.

A similar case is worthy of notice.

The patient, housewife, aged 50, was of an extremely stout habitus, and suffered for 12 months before the date of her operation with an umbilical hernia, of a large size, for which she wore a belt. She was sent to me by Dr. William Thompson, of Waltham Abbey, on April 2nd, 1912, as a case of strangulated umbilical hernia; the history being that the rupture could be replaced until 36 hours before, but, leaving off her belt casually and going to stool, it became fixed externally, this immobility coinciding with the onset of the usual symptoms of acute intestinal obstruction. She continued at

her household duties after descent of the hernia and did a hard day by the wash-tub. On admission this history was confirmed, and the patient, whose general condition was feeble, was prepared for immediate operation. She had a hard swelling above the umbilicus as large as the head of a two-year-old child, hanging downwards from a pedicle and overlying and concealing the natural umbilical scar. The abdomen was opened and the sac exposed and found to be jet black in colour with gangrene; on its incision sanious ill-smelling fluid escaped, while imprisoned inside the mass, and covered by a false sac of sloughing omentum, was found a dilated portion of dead small intestine arranged in groups partly glued together. The constriction was fibrous and extremely tight, situated above the infantile position of the umbilicus, and on section the strangulated gut was pulled down, as a routine measure to inspect the effect of the annular pressure on the coats of the imprisoned neck. Two loops had been incarcerated outside: as a consequence the intermediate part between them was pulled down for examination and was found to be gangrenous and decomposing. (See Fig. 1.) The total gangrenous portion involved, to the extent of three feet, was resected; the general state of the patient being critical, anastomosis was not attempted, but the cut ends were pulled into the wound instead and fixed there for temporary purposes, creating an artificial fistula. (See Fig. 2.) In the evening the patient was much relieved and free from discomfort, while intestinal contents poured freely from that end of the intestine which was physiologically uppermost. Convalescence, in fact, appeared to set in, and I was lured into the hope that success might follow; but this was of a temporary nature, as on the eighth day after operation the patient died. No post mortem was done.

FIG. 2.

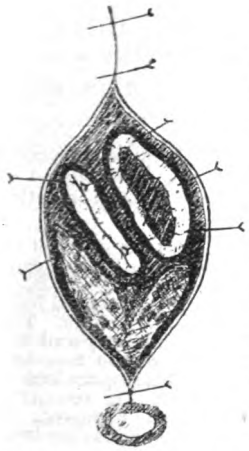


Diagram of parts after operation. The cut ends of bowel are stitched together and to the wound, the lower part of which is packed with gauze.

Pringle [3] records three cases:—

1. Male, aged 27, large scrotal hernia of six years' duration, two loops strangulated externally.

2. Male, aged 55, right inguinal hernia of 14 years' duration, two loops external and irreducible.

3. Male, aged 38, scrotal hernia of 14 years' duration, with three external loops, one normal, one partially strangulated, and one completely strangulated.

This last astonishing case had thus six necks of constriction, and five loops nipped, three external and two internal intermediate connexions, all resulting from one pressure-ring.

Macewen [4] operated on a man with an old-standing mass in the femoral region, attributed to tumour formation, who later developed an increase in the size of the swelling with signs of obstruction. Operation showed an old hernia, non-strangulated, with another recently nipped loop of bowel by its side. The immunity from constriction of the old hernia was due to the thickness of the bowel wall, which, accompanied by masses of "livery" omentum, was possibly a resultant hypertrophy from continued hyperæmia.

Another case was that of a man, aged 26, with a large right inguinal hernia of four years' duration. Lauenstein [5] has the greatest experience of these cases. His interest was first drawn to a patient showing "artificial anus with four lumina," since observing which he has drawn attention to other conditions of a similar nature. The following signs are formulated by him as an aid to diagnosis: 1. The hernia is usually right-sided, scrotal, and of long duration. 2. There may be evidences dependent on a distended condition of the internal loop—e.g., a marked asymmetry in the lower part of the abdomen. 3. There may be a furrowing of the scrotal tumour, with a difference in percussion note over two parts, if one loop contains air, the other fluid.

In my own case here recorded there is an absence of all these points set out by Lauenstein. There was a triple strangulation through the one ring at the umbilicus, two externally and one internally, typical of the condition described by Madyl and Benno Schmidt. The most treacherous cases are those in which no protruded saccular loops are badly nipped, the cœlomic loop alone being affected; the lesson is, of course, that in every operation for hernia the part compressed must be drawn out and *visually* examined, not only to see the condition of that portion so tightly gripped, but also to inspect the inner loops, if present, as to their vitality. The external double-loop strangulation or protrusion itself is of interest, but hardly more than as a surgical curiosity; the resultant inner or retrograde strangulation, be the part originally in the abdomen or be it a second hernia back to the abdomen from the external sac, is of truly vital interest, as if left unrecognised it may cause unaccountable death in cases where loops are casually returned and a radical cure performed without suspicion of the danger which lurks behind. Therefore every case reported will be of value in authenticating a serious disease.

THE TREATMENT OF VARICOCELE BY EXCISION.

BY PHILIP TURNER, M.S. LOND., F.R.C.S. ENG.,
MAJOR, R.A.M.C., T.C.

THE result of the operation for varicocele is by no means always perfectly satisfactory. This has been brought to notice particularly during the war when the operation has been most usually performed on recruits, or on soldiers who have gone sick with this trouble as the result of the strain of service. In these men rapid convalescence and complete recovery are of the greatest importance, while slow convalescence and a persistence of symptoms are a disappointment to the operator who hoped that the men would soon be fit for full duty. Quite apart from the question of neurosis, which certainly does exist in a certain proportion of cases, it is quite common to find a good deal of pain and tenderness persist, often associated with the scar and the induration beneath it where the veins have been ligatured and the divided ends of the varicocele have been tied together.

The usual indication for the operation is the existence of pain and aching, either continuous and persistent or brought on by excessive exertion or by riding, and when the symptoms are only imperfectly relieved by wearing a suspensory bandage. These symptoms are due in part to the dilated plexus of veins and in part to the low position of the testicle, the importance of the latter being shown by the relief often given by the mechanical support of the bandage. The object of the operation should thus be twofold—(*a*) to remove the dilated plexus of veins, and (*b*) to raise the testicle to a higher level and give it better support.

The operation of excision of a varicocele is usually performed in the following manner. The spermatic cord is exposed just below the external abdominal ring; the veins, after division of their fascial covering, are separated from the vas, a few being allowed to remain with this structure. By drawing the cord at first in an upward direction and then downwards the dilated pampiniform plexus is separated as low down as the tunica vaginalis and as high as thought desirable. After ligatures have been securely placed above and below, the intervening mass of dilated veins is cut away, and then, with a view to permanently shortening the spermatic cord and raising the position of the testicle, the ends of the ligatures which have been left long are knotted together, approximating the divided stumps of the veins.

The operation as thus performed certainly fulfils the first of the above-mentioned conditions, but it quite fails to carry out the second. The testicle is not normally suspended by the spermatic cord nor by the pampiniform plexus, neither does its position depend upon the length of the cord. Both suspension and position depend upon the fascial sheath of the cord, composed of cremasteric, intercolumnar, and infundibuliform fascia intimately blended together, which has definite attachments above and is continued below around the parietal part of the tunica vaginalis. The important part played by the sheath in the suspension of the testicle is shown by the action of the cremaster muscle.

The following sequelæ may be the result of the unnatural support given to the testicle by tying together the divided stumps of the dilated veins.

1. There is a "callus-like" inflammatory thickening around the junction of the divided ends. This is often painful and tender and these symptoms may persist for a long time.

2. The inflammatory mass which is formed around the divided veins may become adherent to and incorporated with the surrounding tissue, impeding the free mobility of the testicle.

3. The amount of inflammation may be excessive and suppuration may occur.

4. Generally speaking, the length of the venous plexus which should be excised is greater than the elevation of the testicle which is called for. Thus it is desirable usually to remove three inches or more of the veins, while the testicle should be raised about an inch or an inch and a half at the most. The testicle may thus be unduly raised and its mobility at the same time impaired.

Recently I have endeavoured to overcome these disadvantages by excising the varicocele without joining the divided ends of the veins and procuring increased support to the testicle and raising it to a higher level by shortening the fascial sheath. Various methods of effecting this have been tried. At first I excised portions of the sheath and united the divided ends by sutures or ligatures, but the inflammatory thickening still made its appearance. Lately I have employed the method below which has proved very satisfactory.

The spermatic cord is exposed by the usual incision just below the external abdominal ring; the cord enclosed in its fascial covering is then freed and drawn out of the wound. With a knife or a sharp pair of scissors a longitudinal incision an inch or an inch and a half in length is made through the fascial coverings in front until the veins are exposed. The middle of the incision is secured on each side by a pair of Spencer Wells forceps, which act as retractors. With a blunt dissector the veins are separated from the sheath on each side until the vas, which is situated behind and is more closely connected with the sheath, is reached. The anterior three-fourths or so of the venous plexus, including all the dilated veins, are then separated, leaving the remaining veins with the vas, which is not touched and is not separated from the sheath. The anterior mass of veins is now drawn downwards and a little dissection frees them as high as is thought desirable. Next they are drawn upwards and the separation can now be effected as low as the top of the tunica vaginalis. The separated group of veins is now ligatured above and below and the intervening part is cut away. The ends of both the ligatures are cut short and the testicle is replaced in the scrotum. The sheath is now shortened by retracting the lateral margins of the longitudinal incision and closing this by a fine continuous catgut suture in the transverse direction. It is well first of all to approximate the upper and lower angles of the incision with forceps and to observe what effect this has on the position of the testicle. As a rule, it raises it to a slightly higher level than the testicle of the other side, but if further elevation is considered desirable the length of the original incision can be increased. All bleeding points are then secured, and the wound is closed in the usual way. The great advantage of this operation is that the opening in the sheath is completely closed, and hence the cord and the divided veins do not become adherent to the surrounding tissue. The tender inflammatory nodule around the site of the operation is absent or only very slightly marked, while the testicle remains suspended in a normal manner in the scrotum at a higher level with its mobility unimpaired. I have now operated on six cases at No. 3 General Hospital in this way, and although they are too recent to enable one to speak of the ultimate result, their convalescence has been more rapid and there has been much less pain and fewer after-symptoms than with the ordinary operation. With a little practice the operation thus performed is just as simple and as easily carried out as the ordinary operation and it has the advantage of being much neater.

V.A.D. HOSPITALS.—Totnes, Devon, has had the "Strathmore V.A.D. Hospital" for the past two and a half years. It contains 22 beds, but recently it has been felt that a larger institution was required, and consequently Follaton House, Totnes, has been opened as a V.A.D. hospital with accommodation for 50 beds. Dr. Walter Chapman is the medical officer in charge.—Maxstoke Castle, Warwickshire, which was built in 1345, has been lent to the British Red Cross Society by the Rev. and Mrs. D. L. Lee-Elliott as an auxiliary hospital for convalescent soldiers. It will accommodate 30 patients with the necessary V.A.D. staff.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF GUNSHOT WOUNDS OF FACE AND THIGHS; ŒDEMA OF GLOTTIS; DEATH UNDER NITROUS OXIDE ANÆSTHESIA.

BY G. H. COLT, M.B., B.C. CAMB., F.R.C.S. ENG.,
TEMPORARY MAJOR, R.A.M.C. (T.)

THE following case is worth recording because the occurrence of acute œdema of the glottis, after a small wound of the face, has not been brought prominently before the notice of surgeons since the war began.

Private F., aged 33, was wounded by splinters of shell on Jan. 29th in the upper part of the posterior surface of each thigh and in the right side of the face. Two days later chloroform was administered, and the sloughs removed from the, relatively speaking, small wounds of the thighs. The anæsthetic was administered without any difficulty and the operation lasted 30 minutes. The wound of the face had scabbed over, and in fact the condition in this respect looked so insignificant that it was nearly left alone. On removing the scab a small piece of metal was felt and removed. It was about three-sixteenths of an inch square and larger than the scab. The cavity containing it was gently curetted and a tube inserted. This wound, which led to the death of the patient five days later, was situated half an inch in front of, and half an inch below the level of, the tragus of the right ear. It admitted a small curette to a depth of three-quarters of an inch. No bare bone could be felt. It contained no cloth. It did not communicate with the mouth. No bacteriological examination was made of the interior. For three days all went on satisfactorily, but on the fourth day, six days after the patient had been wounded, the right side of the face was slightly more swollen than it was on the preceding day and a fomentation was applied. In the evening the swelling showed also in the neck and the temperature rose to 102° F. On the morning of the seventh day after the patient had been wounded there was marked œdema of the eyelids on the right side and the patient complained of pain in swallowing. On examination the fauces were seen to be congested and slightly swollen, especially on the right side. At this stage it did not occur to us to examine the larynx; the matter looked simple enough, the swelling of the face and neck being due to insufficient drainage from the abscess. In point of fact two of us well used to anæsthetic work had independently noticed that there was slight respiratory obstruction; both of us had discounted it as being due to the swelling pressing on the right side of the pharynx, and both of us had mentioned the fact to the anæsthetist.

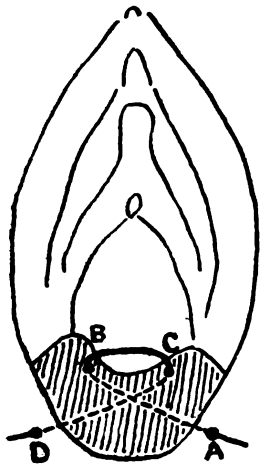
Nitrous oxide gas was administered by the non-rebreathing-valve method. After six inhalations the patient became blue, the administration was stopped, the mouth was opened and the tongue drawn forwards, and two fingers inserted down to the epiglottis and separated. Hewitt's artificial airway was introduced; respiration continued, evidently with considerable obstruction, for about 30 seconds. Spasmodic inspirations followed at intervals of about 20 seconds for something like two minutes, a small amount of air entering and leaving the airway. This made me hesitate to perform laryngotomy, although if such had been done at this stage life would probably have been preserved. Liquor strychninæ ᵐ xxx. was given hypodermically in the pectoral region, the phrenics were faradised and hot cloths applied to the chest. No pulse could be felt in the wrist, but the heart was beating feebly. About five minutes from the start laryngotomy was performed and air then entered freely. Fifteen minutes from the start an incision was made into the abdomen through the upper part of the left rectus and the heart massaged bimanually, this and artificial respiration being continued for 35 minutes. The patient having shown no sign of life for half an hour they were discontinued.

Post mortem there was œdema of the fauces and glottis extending down as far as the upper border of the true vocal cords and on the right side involving also the posterior part of the true cord. The œdema was more marked on the right side than on the left and could be traced to the upper part of the right side of the soft palate near the wound. The uvula was œdematous. The rest of the organs, with the exception of the spleen, which was somewhat enlarged, were healthy and normal. The thymus was not enlarged.

It seems to me that an immediate laryngotomy following on the onset of obstruction to breathing would have saved

this patient's life for the time being, and that it was the only course to have adopted. Laryngotomy is undoubtedly the operation of choice in such a case, for one only requires for its performance a knife and a pair of sharp-pointed scissors, or even a knife alone. The operation seldom takes longer than 20 seconds to perform. The method of drawing forward the skin and transfixing it transversely with the knife, whereby the vessels on the crico-thyroid membrane are left behind uninjured, deserves to be more widely known than it is. The membrane being perforated with the points of the scissors and their blades being then separated the vessels are pressed to each side and hæmorrhage is reduced to a minimum. In the case of a patient with a short, thick, congested neck, for instance a child who has tried to drink hot water from a kettle, this absence of bleeding is a great help. In the case referred to it is probable that laryngotomy would have been needed in a short space of time whether an anæsthetic had been given or not, in fact, the next time that the patient fell asleep.

Particular attention should be drawn to the danger of the onset of œdema of the glottis following a wound in the parotid region. Such œdema is well known to occur in cases of facial anthrax, especially when the pustule is situated near the angle of the jaw, and in cases of wounds of the mucous membrane, notably after extraction of an impacted and septic wisdom-tooth. Not having access at the present time to the literature of the subject I cannot state the relative frequency of its occurrence in these conditions.



The proposed operation which was the immediate precursor of death could have been efficiently and quickly performed without any anæsthetic, but this would have been a painful proceeding.

METHOD OF SUTURING RUPTURED PERINEUM.

BY W. H. BISHOP, M.B., B.S. DURH.

I HAVE long been dissatisfied with the ordinary method of dealing with the perineum when ruptured during labour. The following plan is probably not new, but I have never seen or heard it described, nor have I met with anyone who has used it.

I use a handled needle, such as Spencer's, or Liston's No. 3 (which is excellent), enter it unthreaded through the skin at middle of left side of tear and about ¼ inch from its edge (see Figure, A) and pass it diagonally across the wound and bring the point out just inside the mucous membrane at centre of vaginal wound (B). It is then threaded and withdrawn and drawn off the suture, leaving this projecting from A and B. I now enter it on the other side in a precisely similar manner (at D), using my left hand, and bring it out at point C. The loose end of the suture hanging from B is now threaded and drawn through, making a figure-of-eight loop when the suture is tied. The vaginal loop is first drawn tight and the ends are tied over the skin. Examining now, the perineum is found to be firmly restored, and this can be further demonstrated by leaving the placenta unexpressed till this stage, when it can be so removed without any opening of the wound or forcing of blood through it. Should the tear extend into the rectum a precisely similar suture could be employed posteriorly, but I have not had the opportunity of using it. I consider it better to bury the suture completely, but it can be made to emerge as it crosses the bottom of the wound if preferred, as in the later operation for the repair of an unhealed rupture.

The shaded portion indicates the rupture.

I use catgut No. 3 for the suture. But silkworm-gut could be used and the difficulty of removal overcome by piercing the mucous membrane in the same way as the skin and so leaving the suture exposed in the vagina, great care being necessary to avoid inverting the mucous membrane when tying. This would be divided and withdrawn preferably 24 hours later. The absorbable material is to be preferred, and there are plenty of reliable brands on the market, and many reliable ways of efficiently sterilising it for oneself.

Reviews and Notices of Books.

BOOKS ABOUT THE WAR.

IT is pathetic that many of the books now appearing, and dealing with different phases of the war, should be occupied with the descriptions of the care of the wounded; in a rough way this is an indication of the terrible loss of life and health that the war now means to us, and of the very general way in which these tragedies are distributed through all ranks of our society.

Wounded and a Prisoner of War. By AN EXCHANGED OFFICER. London and Edinburgh: William Blackwood and Sons. 1916 Pp. 316. 5*s.*—This is a narrative of the experiences of an officer who reached France in the second week in August, 1914, fought in the front trench at Mons, was wounded and taken prisoner at Caudry, was nursed back to life by French doctors and nurses at Cambrai—already, of course, in German possession—was sent to Würzburg as a prisoner at the beginning of the following year, and was finally remitted to England in exchange for a German prisoner. It is a studiously simple story and gains in vividness thereby; the odious inhumanity of the Germans to our prisoners, their cowardly desertion of the sick in the prisoners' camps, their brutality to the wretched inhabitants of the occupied towns all emerge as convincing facts from this unpretentious tale.——From the same publishers is issued *The Tale of a Casualty Clearing Station* (pp. 306, 5*s.* net), by A ROYAL FIELD LEECH, a neatly informatory account of a Lospital unit, which accompanied as near the front as possible the British Expeditionary Force at the outset of war. The personnel, with outfit "accurate to the last safety-pin," embarked at Southampton on Aug. 16th, 1914, and went to Havre and thence to Rouen by water, being the first Englishmen since the reign of Henry V. to see that stretch of the Seine from the deck of a military transport. The Mons retreat and the formation of the 1915 front, and the advance on Neuve Chapelle are the sections of the war described, and always described from the point of view of a casualty clearing station. This book is a pleasant and practical note for the medical history of the war.

A Doctor's Diary in Damaraland. By H. F. B. WALKER, M.D., late Captain, R.A.M.C. London: Edward Arnold. 1917. Pp. 207. 7*s.* 6*d.* net.—This is the story of a mounted Brigade Field Ambulance which accompanied General Botha's force into Damaraland early in 1915. Dr. Walker has an observant eye and a skilled pen, and the value of his book lies not in his description of military events—it was his usual rôle to be toiling a long way in the rear of his brigade—but in his attention to the geographical details, which influenced so strongly an extraordinary campaign. Neither the text nor the pictures make the late German colony a very pleasant place, and life in either Swakopmund, Windhuk, or Lüderitzbucht must have been bereft of every amenity.

The prevailing note of Captain Viaud's book (*War.* By PIERRE LOTI. Translated from the French by MARJORIE LAURIE. London: T. Werner Laurie. 1917. Pp. 228. 2*s.* 6*d.* net) is one of horror at German barbarity and sympathy with its tortured victims. Loti's style comes out even in translation, suggesting that the rendering of Miss Laurie is a faithful one; and this series of pictures, which bear dates between August, 1914, and April, 1916, has all the clearness and sentimental grace expected from the author of "Aziyadé" and "Madame Chrysanthème." By the side of such passages as the description of Rheims and of the exploits of the French Naval Brigade the denunciations of the Kaiser read fustian. But Loti is known to be a good hater. In those days when France and England were on the edge of mutual misunderstanding he wrote a book about India without mentioning England, and this was not meant as a compliment to us. We are reminded of this fact by Madame Alexinsky's interesting account of Russian medical organisation in the early days of the war (*With the Russian Wounded.* By Madame TATIANA ALEXINSKY. London: T. Fisher Unwin. 1917. Pp. 180. 2*s.* 6*d.*). The total omission of reference to the British share in the war has been due to the natural fact that the Russian general population can never mention in conversation a country of which they know nothing. In this connexion her husband, in a prefatory note, makes this witty comment: "Russia is an Elephant, while England is a Whale, so that they have few opportunities of meeting and making each other's acquaintance.

But now that the British Whale has made itself feet of steel and is using them to surmount the blood-stained heights of the Somme ..... you may be sure our people will appreciate our noble Ally." Madame Alexinsky's letters describe the passage of a huge hospital train, wherein she had charge of six *tieploushkas* (wagons improvised to carry tiers of cot cases), full of seriously wounded cases, up and down Russia, between the actual trenches, as at the river San, to Petrograd, Moscow, Brest-Litovsk, Warsaw, and Smolensk, and the incidents are depicted with obvious sincerity. They bring before us in striking manner intimate phases of Russian life during the war, and the sufferings and strenuous determination of the country at large to fight to a finish against German tyranny. The book ends sadly with the beginning of the great Russian retreat, but Madame Alexinsky, a prominent Socialist, will find in the recent revolution in her country grounds for hope that the tide of success will soon flow westward.

An accurate impression of life under the hospital organisation which has sprung into such colossal being during the past two years is given in *The Wards in War Time* by A RED CROSS PRO. (London and Edinburgh: William Blackwood and Sons. 1916. Pp. 343. 5*s*. net.) The book is divided into two parts, the first, and, of course, far the longer, dealing with the military hospital proper, and the second with the auxiliary hospital; in both the routine is displayed to us very clearly with many humorous and discriminating character sketches of a hospital population from top to bottom. "Red Cross Pro" has just the equipment and temperament as a writer to do artistically the task he has set himself; his imaginary types live, move, and have their being for our better information.——A little book with somewhat similar outlook directed towards a French hospital (*Letters from a French Hospital*. ANON. London: Constable and Co., Limited. 1917. Pp. 96. 2*s*. net) is far less ambitious. It consists of a series of letters from a niece who is nursing in France to an uncle at home in England, and many of them were not written deliberately for publication. We agree with the uncle, however, who has decided to issue them, that they merit attention, for they show in a life-like way how active many Englishwomen have been moved to be in their attempts to alleviate the sufferings of outraged France. And more, the author of the verses "La Maison de ——" is a real poet both in sentiment and technique.——*Outposts of Mercy*. By E. V. LUCAS. London: Methuen and Co. 1917. Pp. 60. 1*s*. net.—This record of a visit to the various units of the British Red Cross in Italy gives a striking account of the geographical and climatic difficulties with which the Italian army has had to contend. Mr. Lucas made a tour of the Italian front, comprising the Carso, Gorizia, and the Carnic and Julian Alps, and brief though the form may be which his evidence has taken, he proves to us at home how thoroughly our representatives abroad are upholding the national traditions for helpfulness and kindliness. The notes have a humorous as well as a graphic quality. Exactly the same may be said for Miss Spearing's record of the experiences of a V.A.D. (*From Cambridge to Camiers under the Red Cross*. By E. M. SPEARING. Cambridge: W. Heffer and Sons. 1917. Pp. 87. 2*s*. net). Miss Spearing describes how in November, 1914 the university city, already bereft of most of its undergraduates and many of its dons, began to receive wounded Belgians from the early battle fronts. A year later she was sent to Camiers, and thence to other centres in France, and at each place she has gathered reminiscences which she imparts in a charming personal style. The episodes are sometimes pathetic, sometimes funny, and sometimes both, and we feel that Miss Spearing herself lived through her experience half in tears, half in laughter, but always practical and busy.

Hospital Days. By PLATOON COMMANDER. London: T. Fisher Unwin. 1917. Pp. 188. 2*s*. 6*d*. net.—The author has already made his mark in a previous work, "With My Regiment." We thank him sincerely for his graphic testimony to the energy, utility, and self-sacrifice of the doctors at the front, the theme of the most serious chapter in a collection of good things.——*Regimental Silhouettes*, by CHARLES GRIBBLE (London: T. Werner Laurie, Limited. 1917. Pp. 88. 1*s*. net), has a title well describing its contents. The sketch of the regimental medical officer is kind but very goody goody.—— Dr. Cook has a rather uncertain muse. (*The Happy Warrior and Other Poems*. By AUGUSTUS H. COOK, M.B. London: G. Bell and Sons, Limited. 1917. Pp. 85. 2*s*. net.) There are fine thoughts and poetic expressions scattered up and down his verses, and the technique is conscientious which is all the more laudable, as he has a tendency to use the lilting measures not employed by our rising school of poets. The last piece in the booklet, describing the ideal nurse, is quite happy.

Two excellent translations from the French, both of books dealing with the early phases of the war, have been recently issued. The first of these—*The Diary of a French Private, 1914-1915*. By GASTON RIOU. Translated by EDEN and CEDAR PAUL. (London: George Allen and Unwin, Limited. 1917. Pp. 315. 5*s*. net)—is an important work. M. Gaston Riou is a leader of young French thought and a devout Christian democrat, whose volume entitled "*Aux Écoutes de la France qui Vient*," has expressed to a wide audience the ideals of a group of the finest Frenchmen of the present generation. Having an intimate knowledge of German life and the German language, he received during the year's imprisonment imposed on him at Ingolstadt, despite the fact that he was a Red Cross official, valuable and intimate impressions of how the German people regard the war. He shows how the young German intellectuals, professing the same noble and sometimes religious aspirations as his own school of thought, fell willing victims to Prussian schemes of national aggrandisement, even though their loathing for the political system, which vested autocracy in illiberal leaders, might be expressed in language as uncompromising as any that a Russian patriot could employ. This simple record of the life of a war prisoner in Bavaria is a work of art, so convincingly are the details of a terrible monotony infused with high thinking and brought out by admirable writing, and so glowing is the love of France that burns in the writer's soul.——*Battles and Bivouacs: A French Soldier's Note-book*. By JACQUES ROUJON. Translated by FRED ROTHWELL. London: George Allen and Unwin, Limited. 1917. Pp. 256. 5*s*. net.—This book is also well worth reading. It gives the impression of a totally different young Frenchman, a brave unheeding simple soldier, caring nothing for ultimate causes and determined only to fight, suffer, and die for France. M. Riou and M. Roujon have little in common save their patriotism, but by that link alone they must love one another. This recital of the first six months of warfare demands attention by the vivid and minute way in which it describes the sensations of a young soldier and the episodes in a life of furious fighting.

We include in the literature of war such pamphlets as Mr. Lansbury's moving call to the nation to deal with labour questions on Christian principles, and Mr. Ashbee's exposition of the views of the United States on the questions of national armaments and industrial ethics (*The American League to Enforce Peace, an English Interpretation*. By C. R. ASHBEE. 1917. Pp. 92. 2*s*. 6*d*. net, and *Your Part in Poverty*. By GEORGE LANSBURY. 1917. Pp. 126. 1*s*. net. Both London: George Allen and Unwin), for in each case the social conditions brought about or accentuated by the war are under consideration, and the intention of the writers is to urge the world to ensure a general amelioration of them. Both writers are speaking for industrial democracy in the same spirit, and with the same faith in the good sense of the people at large. There is nothing medical about the arguments put forward by either, but sincerely humanitarian ideals will always have the support of the majority of medical men, to whom the miseries and muddles of social life are necessarily revealed with particular clearness.

JOURNALS AND MAGAZINES.

Archives Médicales Belges. Editorial Committee: MM. Brachet, Debaisieux, de Marneffe, Denhaene, Depage, Derache, Gaudy, Hainaut, Henrard, Labasse, Maistriau, Nolf, Renaux, and Willems; Secretaries: M. Stassen and J. Voncken. Seventieth year. Nos. 1, 2, and 3, January, February, and March, 1917. Pp. 1-288. Price, annually, non-occupied Belgium and France, 16 fr.; abroad, 18 fr.; monthly number, 1 fr. 50; Paris: Librairie J. B. Baillière et Fils, 19, Rue Hautefeuille.—The publication of this monthly journal has been resumed after two years' abeyance owing to the war. The journal is open not only to communications dealing with war medicine and surgery but to all medical, scientific, and social work. With reference to social work, the editorial committee's programme contains the following words: "La médecine sociale n'occupait pas encore en Belgique la place qui lui était due; le retour au temps de paix montrera combien elle était indispensable et combien les réformes qu'elle suscitera aménéront un mieux-être de notre peuple."—The January number contains articles by Dr. P.

Derache on Wounds of the Knee-joint from Projectiles; by Dr. E. Renaux on the Malarial Fever of Flanders; and by Dr. René Sand on Social Medicine in England. Following these comes a résumé of the lesions of peripheral nerves in the war and reviews of European and American medical and scientific journals, concluding with a short account of the origin and position of the Belgian Doctors' and Pharmacists' Relief Fund. —The February number contains articles by Dr. P. Nolf on Injections of Peptone in the Treatment of Typhoid Fever and other infectious conditions; Dr. L. Wilmaers and Dr. Renaux on 47 cases of Ictero-Hæmorrhagic Spirochætosis; and Dr. Henrard on Localisation of Foreign Bodies, with numerous diagrams.—In the March number Dr. Stassen discusses the professional re-education of those mutilated by the war. We congratulate the promoters on the resuscitation of the archives.

Journal of Anatomy.—Part II. of this reorganised periodical fulfils in every way the expectations that have been formed for the future of the organ of the Anatomical Society. The papers published in this issue cover a wide range of anatomical subjects, deal with problems of sufficient importance to render them permanently valuable, and have entailed in their composition more research than is involved in the mere recording of a dissecting-room anomaly.—A timely contribution is that by Professor M. Boule and Professor R. Anthony, which deals with the interpretation of the endocranial casts of fossil man. The authors give sound reasons for supposing that those who have discarded such interpretations as highly speculative and fallacious have gone a good deal too far; and they adopt the logical standpoint that positive evidence, when it is available, should not be discredited because in other cases positive evidence is not to be obtained. No form of investigation should be neglected in the study of the fragmentary remains of earliest man, and to disparage research, because in some cases that research can only produce negative results, is poor service to science.—A paper which contains a valuable summary of the condition of the branchial arteries in reptiles is that by Dr. Charles H. O'Donoghue, and the utility of the contribution is enhanced by the timely effort made to define rigidly that channel to which the term "ductus Botalli" is rightly applied.—Professor T. H. Bryce and Dr. Matthew Young give the detailed results of their observations on metopism. The work was carried out on a long series of West Scottish skulls preserved in the anatomical department of the University of Glasgow, and the findings furnish a valuable and permanent contribution to the literature of physical anthropology.—The same may be said of Dr. W. L. H. Duckworth's notes on measurements made on subjects in the dissecting-room. The author attempts to correlate head measurements and skull measurements, a research which might well be carried on in other anatomical departments. —Dr. R. H. Robbins contributes a paper on the human pisiform; the study constitutes a preliminary to a more extended communication on the comparative anatomy of this bone.—Another paper is added by Professor F. Wood Jones to the series dealing with the comparative anatomy of the genitalia; in the present communication the reproductive system of the tree shrew (*Tupaia*) is described and illustrated.—Two papers which hold rich possibilities of useful surgical application are those by Mr. V. Zachary Cope on the sphenoidal air sinus, and Mr. Alwyne T. Compton on the intrinsic anatomy of the sciatic nerve trunk.

The *Cornhill Magazine* for May contains, in an article by Mr. Lewis R. Freeman, on the work of the British Red Cross and Order of St. John, Italy, an amazing story of resourcefulness on the part of an ambulance driver:—

> One of the voluntary drivers was bringing down, over an especially difficult piece of road, an ambulance full of wounded from a lofty sector of the Alpine front, when he encountered a soldier in a desperate condition from a gaping bullet-wound in the throat. "Realising that the man was in imminent danger of bleeding to death, the driver lifted the inert body to his seat, propping it up the best he could next to where he sat behind his steering-wheel. Driving with his right hand, while with a finger of his left he maintained a firm pressure on the severed carotid artery, he steered his ambulancee down the slippery, winding mountain road to the clearing station at the foot of the pass. The laconic comment of the astonished, but highly pleased Italian doctor on the incident was direct but comprehensive. "Well, young man," he said, as he took hasty measures further to staunch the gushes of blood, "you've saved his life, but in five minutes more you would have throttled him."

Owing to the amalgamation of the famous publishing house of Smith, Elder, and Co. with the no less famous house of John Murray the *Cornhill Magazine* has been transferred to the latter firm.

Reports and Analytical Records
FROM
THE LANCET LABORATORY.

CRYOGENINE (LUMIÈRE).

(THE ANGLO-FRENCH DRUG COMPANY, LIMITED, GAMAGE BUILDING, HOLBORN, LONDON, E.C.)

As an antipyretic and analgesic cryogenine has been known for some time, but now that certain restrictions have been placed on the supply of phenacetin further attention to its therapeutic properties may be given. Chemically it is a benzoic acid derivative and is known as meta-benzamidosemicarbazide. It is a white crystalline powder freely soluble in ether, chloroform, and benzene, and to the extent of about 1 per cent. in water at 20° C. It has a marked reducing action which is strikingly shown with Fehling's solution. The blue colour is reduced in the cold to green, and on heating the fluid a rapid reduction to red cuprous oxide occurs. This reaction readily enables the detection of the drug when it is eliminated in a non-diabetic or non-glycosuric urine. Clinical experiments are quoted showing its value in reducing pyrexia and in diminishing pain, particularly in neuralgia and rheumatism. These effects are said to be unattended with secondary phenomena. Its administration leads to a strong yellow tint in the urine not referable to biliary pigment, but due to oxidation of the drug itself.

VAPOROLE CHLOROFORM.

(BURROUGHS, WELLCOME, AND CO., SNOW-HILL BUILDINGS, LONDON, E.C.)

These vaporoles, each containing 3 minims of chloroform, may well serve a useful purpose. The chloroform is contained in a thin glass tube wrapped in wool and an outer case of gauze. The tube is easily crushed by pressure between the thumb and finger and chloroform vapour so liberated. The suggestion, for one thing, is that the vapour in this way can be used for the relief of earache (not to be used in suppurating cases). To this end the capsule is broken and placed in a small vessel, such as an egg-cup, which is then held close to the affected ear. It may also be used when inhalation of a small quantity of chloroform vapour affords temporary relief in asthma or croup. This small measurement of chloroform renders its use safe.

TOILET SOAPS.

(PRICE'S PATENT CANDLE CO., LIMITED, BATTERSEA, LONDON, S.W.)

We have examined two specimens of toilet soap recently introduced by this well-known firm under the names respectively of "White Clover" and "Santal." Both proved to be perfectly neutral soaps, giving no evidence whatever of the presence of free alkali. There were, in fact, no extraneous ingredients found at all except perfume, which in the one case ("white clover") was of a light, agreeable, "grassy" character, and in the other ("santal") a heavier perfume of oriental style. The moisture in the former was 10·6 per cent. and the combined alkali 9·3 per cent. (Na_2O); in the latter the moisture was 9·1 per cent. and the combined alkali 9·5 per cent. (Na_2O). Both specimens gave a pleasant and economical lather, perfectly smooth and cleansing to the skin.

BLENOSAN CAPSULES.

(ROBERT FERBER AND CO., 98–104, OAKLEY-STREET, WESTMINSTER BRIDGE-ROAD, LONDON, S.E.)

This combination of the essential resins of kava-kava, the root of *Piper methysticum*, with santal-wood oil is said to be serviceable in relieving pain and the constant desire to micturate in gonorrhœa. Kava-kava is referred to as possessing an anæsthetic action on the urinary passage, and an anaphrodisiac. Blenosan is a clear greenish oil in which the resin of kava-kava is dissolved in santal oil. It is interesting to note that a beverage is made from kava-kava which produces a mild drowsiness in the consumer.

LIQUEUR RUM (MEDICAL RESERVE).

(H. N. GILBEY, 15, 17, 17A, CHARLOTTE-STREET, TOTTENHAM COURT-ROAD, LONDON, W.)

Genuine rum is sharply distinguished from all other ardent spirits by containing a considerably larger amount of volatile ethers. They are probably formed during fermentation by the action of the acids in the sugar on the alcohols. There can

be little doubt that on this account rum is a more rapid and powerful stimulant than the other spirits, and possibly this may be a reason for retaining it for the use, under supervision, of the military and naval services. The analysis of the specimen described above gave the following results:—Alcohol by volume, 40·14 per cent. (equal to 30° under proof); extractives, 0·41 per cent.; mineral matter, 0·15 per cent. The secondary products given in parts per 100,000 parts of alcohol present were as follows: Volatile acidity reckoned as acetic acid, 75·0; ethers, 176; aldehyde, 12·5; furfural, 2·5; higher alcohols, 125. These figures are quite in accordance with those yielded by a genuine old mature rum. The spirit possessed the peculiar characteristics in regard to aroma and taste of genuine rum, and was "round" and smooth to the palate. The ethers occur to about twice the quantity found in genuine Cognac brandy, but show some reduction owing to the dilution now required by the State to a maximum alcoholic strength of 30° below proof.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

SUBSCRIPTIONS.

THE following additional subscriptions to the Fund have been received:—

	£	s.	d.
Dr. Burrowes	1	1	0
Royal College of Physicians of Edinburgh, for the North British Branch of Pharmaceutical Society of Great Britain (per Dr. Norman Walker)—			
Subscriptions in hand, April, 1915	0	15	0
Dr. James Caskie	1	1	0
Mr. R. Hay	0	10	6
Mr. H. Dryerre	1	1	0
Edinburgh District Chemists' Trade Association (per Mr. A. A. Murray)	2	2	0
Mr. W. G. Johnstone	1	1	0
Mr. J. S. B. Heddle	0	10	0
Mr. Alex. Inglis	0	10	0
Dr. G. D. H. Carpenter (24th donation—total £24)	1	0	0

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund crossed Lloyds Bank, Limited.

THE APPEAL FOR SURGICAL INSTRUMENTS.

Surgical instruments should be sent to the Master of the Society of Apothecaries, Apothecaries' Hall, Blackfriars, E.C.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

THE annual meeting of the Governors and General Council of King Edward's Hospital Fund for London, to receive the accounts and the report of the General Council for the year 1916, was held at St. James's Palace on April 27th, the Duke of TECK being in the chair.

Lord REVELSTOKE, honorary treasurer, in presenting the account of receipts and expenditure and the balance-sheet for the year ending Dec. 31st, 1916, said that the Fund had received support enabling it to put a substantial addition to reserve. This addition, which amounted to no less than £143,000, was due mainly to the receipt of £137,000 on account of the residue of the estate of the late Lady Wilton. Since the end of the year a further sum has been received, raising the total of the bequest to £163,000. The net loss on the realisation of investments shown in the balance-sheet was due to a sale of the Fund's holding of American securities, which the Finance Committee had considered it their duty to make in response to the invitation from H.M. Treasury, and the re-investment of the proceeds in British Government securities.

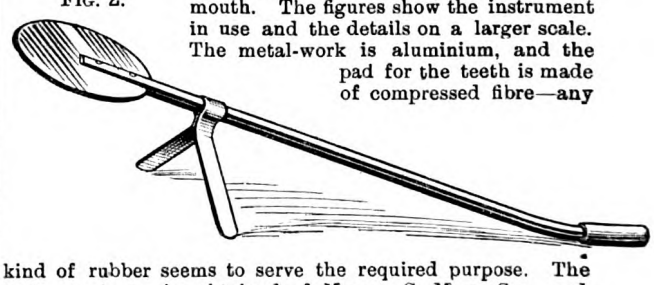
The SPEAKER of the House of Commons moved the adoption of the accounts, which was seconded by Viscount SANDHURST and carried unanimously.

Mr. JOHN G. GRIFFITHS, honorary secretary, presented the draft report of the Council for the year 1916, of which the following is a summary:—

The total receipts for the year 1916 were £326,474 3s. 9d., of which £9447 15s. 5d. were contributions to capital, and £317,026 8s. 4d. receipts on general account, the general fund receipts being made up as follows: Annual subscriptions, £25,403 3s. 6d.; donations, £5837 1s. 5d.; contribution from League of Mercy, £15,000; from the estate of Isabella Countess of Wilton, £137,634 18s. 11d.; from the Lewis estate, £3000; other legacies, £33,418 7s. 8d.; dividends and interest from investments, £96,532 16s. 10d.; from the Trustees of the Bawden Fund, £200. The amount distributed was £170,000, which was £30,000 more than the amount applied to this purpose in 1915, and £12,500 more than the previous maximum appropriation before the war. Of the amount distributed £162,500 were allocated to London hospitals and £7500 to consumption sanatoria and convalescent homes taking London patients, as against £133,500 and £6500 respectively in 1915. Of the £162,500 granted by the Fund to the London hospitals, £128,425 were given in aid of general maintenance, £15,000 to the reduction of debts on maintenance account, and £19,075 toward improvement schemes or in reduction of liabilities on such schemes undertaken before the war. The Fund had continued to encourage the hospitals in the policy of postponing all schemes of capital expenditure not exceptionally urgent or not already in hand at the outbreak of war, and the total grants in aid of new schemes were only £6525. The increase in grants for maintenance over those made in 1915 amounted to £25,900. This large addition to the grants was, however, by no means in excess of the needs of the hospitals. The total sum distributed amongst hospitals, convalescent homes, and consumption sanatoria during the last ten years (after deducting conditional grants to the extent of £6500 that had been allowed to lapse) was £1,544,750. Since the foundation of the Fund a total amount of £2,268,416 had been distributed. The average annual distribution for the whole period of 20 years had been £113,420 16s. 5d. During the year the amount spent on administration was £3161 2s. 3d., or 19s. 4½d. per £100 of the total amount received, as compared with £3205 16s. 1d., or £1 8s. 3d. per £100, last year. The corresponding percentage for the whole period since the inauguration of the Fund had been £1 4s. 3d., or less than 3d. in every £1 received, the average yearly outlay in this respect being £2836 2s. 8d. The League of Mercy this year had contributed £15,000, a larger sum than was received from the League in any of the last three years. The total amount contributed to the Fund by the League of Mercy since its foundation in 1899 now amounted to £245,000, apart from the sums awarded by the League to institutions outside the area of the Fund's distributions. The legacies received during the year included, in addition to the bequest of the late Isabella Countess of Wilton and a further amount of £3000 from the Lewis bequest, £20,193 19s. 5d. from the late Lady Brownlow, widow of Field-Marshal Sir Charles Brownlow; £10,000 given by the executors of the late Mr. Thomas Stephen Whitaker in the exercise of their discretionary powers; and £5000 to capital from the late Rt. Hon. Sir Andrew Richard Scoble.

Viscount IVEAGH moved the adoption of the report, which was seconded by Viscount KNUTSFORD and carried unanimously.

New Inventions.



AN INSTRUMENT TO ENABLE ARMLESS MEN TO TURN OVER THE LEAVES OF BOOKS.

ONE of the great difficulties with which men who have lost both hands have to contend, is turning over the leaves of books they may be reading. With the aid of Captain C. G. M. Hatfield of the 18th Middlesex, and Mr. Barker of the Engineering Laboratory, I have devised a small instrument, one end of which is held between the teeth and the other—which is provided with an indiarubber cap—is pressed against the leaf and with a little practice the leaf can be readily turned over. The instrument is raised on two diverging feet so that one end is lifted off the level of the table and can be easily picked up by the mouth. The figures show the instrument in use and the details on a larger scale. The metal-work is aluminium, and the pad for the teeth is made of compressed fibre—any kind of rubber seems to serve the required purpose. The instrument may be obtained of Messrs. S. Maw, Son, and Sons, 7-12, Aldersgate-street, London, E.C. 1. Price 3s. each.

Christ's College Lodge, Cambridge. A. E. SHIPLEY.

THE LANCET.

LONDON: SATURDAY, MAY 19, 1917.

The Supply of Medical Officers for the Army: Civil and Military Medical Needs.

THE supply of medical officers for the Army has been kept up by the Central Medical War Committee, the Committee of Reference of the English Royal Colleges, and the Scottish Medical Service Emergency Committee, in accordance with the demands of the War Office, and it has been possible to accomplish this by strenuous work on the part of the Executives of those three bodies, in coöperation with Local Medical War Committees which in some districts have worked with great energy and discrimination. The result, moreover, reflects a real desire on the part of the medical profession as a whole to help their country in its need or the efforts of the Committees would have failed in their object. Without going into the exact figures, which would have no particular meaning unless they were considered in connexion with figures which alter from time to time in accordance with the military situation, as well as with the general statistics of the medical profession, we may say that last week the War Office required 250 additional medical officers by a certain date, and that 234 of them were found within two days of that date. Those who know how firmly in many areas the claims of the civilian population have been pressed, and how scrupulously the right or fairness of exemption has been tested in the cases of appeal, must agree that the results of a system based on a voluntary principle, and still working in the thirty-third month of the war, are creditable to the patriotism of medical men as a section of the community.

There is no doubt, however, that the Committees entrusted by statute with the duty of recruiting the members of the medical profession for military services have nearly come to the end of their resources. This has been signified quite plainly to the War Office during the last few days, and must have been common knowledge to the medical profession as a whole, for the local efforts to spare practitioners and to fill the gaps created become more and more strenuous as time goes on and as the War Office needs remain unsatisfied. There are certain areas from which only incomplete returns have been made as yet to the Central Medical War Committee, and there are medical men about whose arrangements the Local Medical Committees are doubtful, and other medical men who, according to these Committees, cannot be spared unless the principle of substitution is put in hand in some large and general way. From these sources a certain number of medical men can still be obtained whose age and qualification are quite in keeping with their acceptance of commissions, but it must not be forgotten that a proportion of these men will certainly be rejected on physical grounds, and it may be that some who still are calculated in the returns as potential officers have already failed to come up to the physical standard. It is also believed that, depleted as the ranks of the men holding whole-time appointments may be, a further contribution can be obtained from them, and in this direction the substitution of women doctors, which has already proved so helpful, may be open to extension. Comprehensive estimation of the whole supply at the disposal of the three Committees shows, therefore, that the material remaining is capable of yielding only a very small number of men, and that the civilian public is already putting up with a marked shortage. This suggests inevitably that unless some difference is made in the methods of employment of the medical men when they have received commissions, some method, that is, which would enable economy to be effected, the public will have to ration itself as rigidly with regard to the ministrations of medicine as they have to with regard to cereal foods. Unfortunately, any real dearth of medical service in a country has a more lasting and worse effect on a population than a period of scarcity of food, for the latter, when remedied, is found to leave a far less lasting effect. The machinery for the distribution of food remains intact and soon returns to normal working, but the machinery for the maintenance of national health cannot be laid aside and suddenly resumed. This being so, it is obvious that we must look anxiously on all sides for economical plans in the employment of our medical personnel. Already most civilian communities are working their hardest to dispense with unnecessary medical aid, and every civilian hospital does, in addition to its ordinary medical work, extraordinary work of a military nature, performing the increased duties with a decreased personnel. Already the medical administration of many public authorities is shorthanded, and, magnificent as the substitution work of the recently qualified women who have taken men's places has been, there is no doubt that much valuable preventive and sanitary organisation has been arrested in its development. Therefore, it is inevitable that we should find the eyes of many fixed on the Army, with the question on their lips whether th military needs cannot in any way be made less by some reforms in the employment of the medical material already supplied.

We have in these columns pointed out over and over again, in reply to ill-considered criticisms of the medical administration of the Army, that local must not be taken as an indication of general conditions. Time after time we have had communications from correspondents saying that at a certain time in a certain place there appeared to be a certain number of medical officers whose work was very light, and that if this was the state of affairs which prevailed throughout the Army, there could be no wonder at a position of shortage being quickly reached. For these critics

the conditions of training and the periods of transition had no being; they saw what lay beneath their eyes and failed to imagine that a supply of medical men can only be forthcoming at a desired spot without delay by placing them more or less in communication with that spot some time beforehand. We would not say that none of these critics was ever right, but it remains a fact that their general message was incorrect. Now, however, the position is somewhat altered. We have been at war for a long time, and the scope of our military activities is far better defined than it was during 1915 and 1916. We occupy a different attitude towards our powerful enemies, the initiative, generally speaking, is with us, our needs can be forecast, and there is not the same necessity to keep idle, against an unexpected demand or a rapidly projected expedition, large medical personnel. Whereas in the early days of the war it was absolutely necessary to leave to the War Office the right to ask whatever men they required from the medical profession, the circumstances are now modified, if only by the response already made by the profession to the War Office. For it must be remembered that some of the best civilian medical brains have been obtained by the Army from the earliest days of the war and a proportion of these officers have been engaged in the work of medical organisation for over two years. They possess what are of necessity largely denied to the regular members of the Royal Army Medical Corps—namely, a knowledge of the conditions of the civilian medical life and a familiarity with the civilian needs. We feel that the inclusion of these men in the Royal Army Medical Corps should make it quite easy for the military authorities to enter into intelligent conference with civilian medicine, and that from such a laying together of heads solid good would be derived. Such matters as the staffing of Voluntary Aid Division hospitals and the employment of medical men in part-time military posts could, we believe, be settled with a real saving of *materiel* by a conference between people equally alive to military and civilian needs.

The Vital Statistics for the First Year of War.

THERE is not yet a Ministry of Health, although in receiving a deputation on infant welfare last week Lord RHONDDA said he was becoming more and more convinced of the need for one, adding a hope that the Ministry, when created, would be largely based on the present Local Government Board. One substantial ground for this need is given by the figures of Sir BERNARD MALLET, the Registrar-General, who has recently issued his report for the year 1915.[1] This report, although dealing with matters 18 months distant, gives information to our profession that has not appeared in any document previously issued from Somerset House. We limit our comments in the main to the salient vital statistics of the year, because the facts of natality and mortality for 1915 have already appeared in the Annual Summary issued in March of the following year. In that publication, however, the facts were derived from returns furnished by the local registrars, whereas the statistics for this report are compiled from the statutory registers and are analysed in considerable detail by experts in the central office.

From the Statistical Section of the Registrar-General's report we learn that the marriage-rate for 1915 was the highest on record; it was equal to 19·5 per 1000 living, and exceeded the average rate in the ten preceding years by 4·1 per 1000. The birth-rate, 22·0 per 1000, was the lowest hitherto recorded, and was in defect of the decennial average by 3·5 per 1000. Nevertheless, the fall in the English birth-rate in the year under notice compares favourably with the experience of other belligerent countries. The civilian death-rate was 15·7 per 1000, and although 1·2 above the average in recent years for the whole population, was yet below this rate in any year before 1903. The rate among civilians is adversely affected (*a*) by the withdrawal for service abroad of a large body of men whose mortality experience is below the average rate at the same ages, and (*b*) by the fact that the men remaining in the civil population at military ages are on the whole less healthy than those who have been withdrawn. Although the standardised mortality of 1915 exceeds the standard of the immediate past, the excess is smaller than might have been anticipated in the circumstances. Apart from the abnormally high death-rate of men of military age who have remained at home, the increase of mortality in 1915 mainly occurred in later childhood and in old age. There is still no provision for the registration of still-births, although, in view of the present dangers to child life, the vital importance of this information was emphasised in 1904 in the report of the Committee on Physical Deterioration. Of the total deaths registered in 1915 in England and Wales almost 16 per cent. were those of infants under the age of one year, corresponding to a mortality of 110 per 1000 births. The immediate chances of survival differ but little at birth in the towns as compared with the country, but the noxious influences of town life speedily appear and make themselves felt increasingly as the first year of life progresses, and to a still greater extent in the second and third years, when the urban excess generally approaches 100 per cent. The fact has, however, been recently brought out by Sir ARTHUR NEWSHOLME in a report on child mortality that the relatively low death-rate in rural districts is attainable under urban conditions by enlightened administrative measures. The mortality during 1915 of illegitimate infants was about twice as high as that of children born in wedlock. Among male infants the excess was highest at ages from one to three months, and among females at ages from three to six months. The mortality of illegitimate infants exceeds that of legitimate infants, more particularly in the case of deaths attributed to syphilis, which are nearly eight times as many. Probably ther is less reluctance to

[1] Seventy-eighth Annual Report of the Registrar-General.

certify the true cause of death in the case of these infants, but the difference is greater than can be explained in this way. Before leaving the subject of infantile mortality it is only fair to point out that the figures given in the returns of medical officers of health for 1916 are almost uniformly lower, in some cases much lower, than those for 1915, and this fall is of particularly good omen, having regard to the circumstances of war in the midst of which it occurred.

Except in the case of scarlet fever, enteric fever, and diarrhœal diseases, most of the principal causes of death showed increased mortality in 1915 as compared with the previous year. The death-rate from enteric fever was the lowest on record, but influenza was more fatal than in any year since 1900, and measles was exceptionally destructive to child life. Another special feature in the year's mortality is the abnormally high death-rate from cerebro-spinal fever, consequent upon the first outbreak in recent years of this very fatal disease. The figures for 1916 and those at present available for 1917 show that this high mortality has not been maintained, especially in regard to the civil population. The mortality atributed to diphtheria and croup in 1915 was practically the same as that of the preceding year, and the rate of both years was heavier than at any time since 1908. In each of the last five years the county boroughs of Northampton and Stoke-on-Trent experienced a diphtheria mortality in excess of that for England and Wales. This fact confirms the statement emphasised in previous reports, that in the tendency to recurrence of high mortality in successive years in the same area diphtheria resembles enteric fever and scarlet fever. The mortality from pulmonary tuberculosis showed a marked increase among males and a slight increase among females, but it must be remembered that the rates for 1915 relate exclusively to the civil population and that enlistment has withdrawn a very large number of healthy males at ages considerably affected by the incidence of tuberculosis. Judged by the ordinary or crude death-rates in 1915, a higher mortality than in any other year was caused by malignant disease, but, in view of the present abnormal constitution of the civilian population, this form of statement is misleading in dealing with such a disease as cancer. When these death-rates are standardised, as they should always be, comparison shows that the mortality of both males and females from this disease was slightly below that of either of the two preceding years. Taken as a whole, and seen in the light of later experience, Sir BERNARD MALLET'S report is an important and vastly interesting chronicle of the first completed year of the war in its effect on the nation's health. The appearance of the report for 1916 will be awaited with impatience, tempered by the fact that a rough comparison is already available from other sources.

CENTENARIANS.—Mrs. Mary Paige died at Rochester on April 24th. She was born near Launceston, Cornwall, on Nov. 2nd, 1815.—Mrs. Mary Shittler died recently at Holwell, near Sherborne, aged 103 years.

Annotations.

"Ne quid nimis."

PUBLIC HEALTH AND THE CONTROL OF THE LIQUOR TRAFFIC.

IN his lecture delivered on Wednesday last at the Royal Institute of Public Health Lord D'Abernon, chairman of the Central Control (Liquor Traffic) Board, dwelt on the curious fact that with one trifling exception the State has hitherto never attempted to regulate the conditions of the liquor trade on grounds of public health. The protection of revenue, the safeguarding of public order, the maintenance of morals, have afforded occasion for restrictive measures, but even the Public Health Acts barely allude to the hygienic dangers of the public-house. He regards this as the more remarkable since the important part which alcohol plays in the causation of suicide and accident, in the diffusion of venereal diseases, in the mortality from many diseases not themselves due to alcohol, and in the production of infantile mortality is an old and familiar fact. Lord D'Abernon went on to show how the policy of reasoned and moderate restriction had already resulted, beyond doubt, in reducing alcoholism, as shown not only by the diminished number of convictions for drunkenness and of deaths from excessive drinking, but also by a corresponding diminution in delirium tremens, which was generally admitted to be an index of less overt forms of intemperance. The latter conclusion he based upon the figures for the cases treated in Liverpool infirmaries for three periods of 12 months each provided him by the Poor-law officials. The issue of the third report of the Central Control Board on May 7th gives the general reader also the opportunity of studying the striking figures in regard to the diminution of convictions for drunkenness in the area under the Board's control. One instance will suffice. In the four weeks immediately preceding the issue of the Control Board's Orders the weekly average of such convictions was 3956; for the same period ending March 25th the average was 1755, or less than one-half the number. Lord D'Abernon's conclusion, therefore, seems a fair one, that intemperance can be diminished in considerable degree by legislative and administrative action. Important, and almost new, as this conclusion is, there remain many problems in relation to the drink question which await solution, and we therefore welcome the appointment of an advisory committee by the Control Board which we foreshadowed in THE LANCET of July 29th last.

The composition of this technical committee was given by Mr. Kellaway, Parliamentary secretary to the Ministry of Munitions, in the House of Commons in answer to a question by Sir W. Collins, viz.: Lord D'Abernon (chairman), Sir G. Newman, Dr. A. R. Cushny, F.R.S., Dr. H. H. Dale, F.R.S., Mr. M. Greenwood, jun., Dr. W. McDougall, F.R.S., Dr. F. W. Mott, F.R.S., Dr. C. S. Sherrington, F.R.S., and Dr. W. C. Sullivan. The terms of reference are as follows: To consider the conditions affecting the physiological action of alcohol, and, more particularly, the effects on health and industrial efficiency produced by the consumption of beverages of various alcoholic strengths, with special reference to the recent Orders of the Central Control Board, and further to plan out and direct such investigations as may appear desirable, with a view to obtaining more exact data on these and cognate questions.

As Lord D'Abernon pointed out on another recent occasion, the problem of drunkenness has become

numerically a smaller one, and it should therefore be now possible to apply more specialised methods in dealing with it. We shall not be wrong in expecting from the technical committee, with its abundant scientific equipment, suggestions for methods which may well solve many of the hygienic problems of the drink question within our own time.

THE LARDER AND THE DUSTBIN.

REGULATIONS affecting the economic management of both the larder and the dustbin have recently been issued by the Local Government Board, and to these special prominence has been given by a prosecution which took place early in the week on account of bread found in the dustbin. In the case of the larder a definite order has been given conferring on local authorities and their officers the powers and duties of enforcing certain provisions set out in a schedule. The Order leaves it to the local authority to arrange as it thinks fit for enforcing these provisions. Any expenses incurred by a local authority in the execution of this Order are to be counted as work carried out under the Public Health Act, 1875, or the Public Health (London) Act, 1891, as the case may be, and defrayed accordingly.

The schedule sets forth that part of the various Orders issued in respect of which the powers and duties are conferred and imposed upon local authorities and their officers. In the cases of the Bread Order, 1917; the Swedes (Prices) Order, 1917; the Food (Conditions of Sale) Order, 1917; the Tea (Nett Weight) Order, 1917; the Public Meals Order, 1917; the Cake and Pastry Order, 1917; the Wheat, Rye, and Rice (Restriction) Order, 1917; and the Maize, Barley, and Oats (Restriction) Order, the local authorities are instructed to carry out the whole of the provisions. In the cases of the Brewers' Sugar Order; the Potatoes, 1916, Main Crop (Prices) Order (No. 2), 1917; the Price of Milk Order, 1917; the Feeding of Game Order, 1917; the Sugar (Confectionery) Order, 1917; and the Manufacture of Flour and Bread Order (No. 2), 1917, only certain clauses of the Order as regards the powers of local authorities come within their exercise.

It is to be hoped that this comprehensive Order will work smoothly, as it can only do if it receives the loyal coöperation of the householder, and is administered by the local authority with fairness and individual consideration.

The immediate removal of household refuse becomes of pressing importance now that the heat of summer has begun to assert itself, and the householder who scents danger to himself and his family from the accumulation of his own waste products should realise that here also his coöperation is essential to a proper safeguarding of the national health. The circular just issued by the Local Government Board to local councils frankly recognises the difficulties under which the removal and disposal of refuse are now carried out by local authorities, and suggests methods of facilitating their work. Householders are encouraged to sift out and burn cinders, to separate kitchen refuse from waste paper, cardboard, and like substances, and to burn either of these if not duly collected. Householders may have to be asked to place their refuse-bins where they can be emptied with least labour. The coöperation between householder and scavenger thus suggested should be undertaken cheerfully by all right-minded men and women. The labour involved will not be great, and if some of the economies resulting from it would have been looked upon as petty in days now bygone they are of real importance now. To burn cinders until they are incapable of producing further heat will help to preserve a coal-supply which is now neither ample nor cheap. Broken cardboard boxes and waste paper used to kindle fires will save wood, the scarcity of which is roughly indicated by its greatly augmented price. That fires can thus be lighted easily, especially in kitchen ranges or where there is a good draught, is probably not realised by many who still look upon "fire-lighters," which consume resin or paraffin unnecessarily, or firewood especially prepared in bundles for the purpose and used with reckless prodigality, as essential to the kindling of coal. To burn all vegetable refuse which cannot be utilised for the feeding of pigs and other domestic animals will be a matter of trouble rather than of difficulty where there are kitchen ranges heated by coal. Where this is not the case a bonfire in the garden will result in ash useful for manure. In town houses where there are no gardens, and where only gas is used in the kitchen, it will not be so easy for the private individual to get rid of organic refuse, although neat and simple gas destructors are specially made for this purpose. The town householder's duty will consist mainly in seeing that as little as possible accumulates, and that this little is kept well protected from flies and under conditions preventing it from offending his family and neighbours until it can be removed.

GENERAL HUMAN CYSTICERCUS INFECTION.

HOWEVER rare and interesting may be a case of human cysticercosis in generalised form and diagnosed during life, the clinical record of such a case would be devoid of real practical and scientific importance if it did not tend to elucidate those details of pathology and symptomatology which have remained hitherto obscure. Dr. Andrea Boccavilla, in reporting such a case (*Il Policlinico*, Medical Section, Feb. 1st, 1917), considers that it merits special consideration both in regard to the nature of the pathological condition caused by the infection, its symptomatology, and the elaboration of the diagnostic methods already known and the eventual acquisition of new ones. The symptoms of the case were instructive as a whole and in connexion with the elective seat of the parasite in man—i.e., muscles and brain. The case exhibited, besides the presence of nodules of cysticercus in the skin, the following prominent symptoms: severe general malnutrition and intense blood dyscrasia, dyspepsia and obstinate constipation and phenomena connected with the neuromuscular system, one being striking and curious—viz., a brisk plantar cremasteric reflex. Dr. Boccavilla undertook some important serological investigations which yielded interesting results. Precipito-reaction was positive in all instances with an antigen of *Cysticercus cellulosæ*, negative with an antigen of *Cysticercus bovis*. Deviation of the complement: results strongly positive for antigens from *C. cellulosæ* in dilutions of 1 in 10, negative in controls with antigen of *Tænia inermis*. Abderhalden's test was strongly positive with an antigen of *T. solium*. A further series of experiments showed a defective absorption both of nitrogen and phosphorus. The details given of this case point to the conclusion that cysticercus infection, especially if generalised, may produce in man a condition of toxæmia with definite changes demonstrable by serological tests and marked disturbance of metabolism. Clinically the symptoms of human cysticercosis, although they may be few and ambiguous, yet in some cases

in which the tolerance of the individual to the toxæmic condition is limited, assume a character entirely *sui generis* and such as to permit, under the guidance of an accurate semeiological study, a diagnosis of great probability, even apart from any specific investigations. Hence when an individual is observed to be the subject of a severe organic toxic condition, not attributable to any special infection, and presents phenomena referable to a multiple intracranial localisation or exhibits evident signs of muscular hyperexcitability to various stimuli accompanied by intense hypokinesis, early exhaustion, irregularity of the ergographic curve, without myotonia or change in the electrical reaction, then the possible existence of a latent cerebral and muscular cysticercosis must be taken into consideration even in the absence of intestinal evidence or peripheral cutaneous nodules. The suspicion will develop into probability if clinical investigation can eliminate the presence of tuberculosis, cerebral syphilis, or idiopathic myopathy. Finally, the diagnosis of latent cysticercus infection will derive valuable aid and confirmation from the application of serological methods, especially those of the precipito-reaction, deviation of the complement, and Abderhalden's test.

THE QUEEN'S HOSPITAL FOR CHILDREN.

AT the annual meeting of governors of the Queen's Hospital for Children, Hackney-road, E., held at the Mansion House on Tuesday last, with the Lord Mayor in the chair, the work and needs of this institution were prominently brought before the public. They are matters with which the medical profession is unfortunately too familiar in regard to civilian hospitals in general. The Queen's Hospital for Children specially serves a surrounding population of at least half-a-million people, mostly of the industrial classes, of East and North-East London, also drawing patients from Tottenham, Enfield, Edmonton, Walthamstow, and Leyton. Pressure on its beds has been greatly increased of late by the military occupation of most of the infirmary beds. The Poor-law authorities are endeavouring to meet their responsibilities with regard to the civil population by carrying out an increased system of out-door medical relief, but this does not meet the case of the sick child in the homes of the poor. Several general hospitals have reduced the work of their children's departments, thus throwing additional responsibility on the special hospitals. The official number of beds at the Queen's Hospital is 134, but last year the daily average of children in the wards worked out at 139, additional cases being put in basket cradles or in extra beds. This work has been done without an increase in the nursing staff, which has remained the same with the greatly increased work. A full medical staff has been kept up by the appointment of qualified women and by temporary appointments to the visiting staff for the period of the war. The accommodation of the seaside branch at Bexhill, opened in 1911 with 30 beds, has been increased by six beds, with the use of open-air shelters throughout the year, and in this way a larger proportion of sick children brought back to robust health. The period of stay at this branch is arranged at the discretion of the medical officer, working out last year at an average of 39 days. The total figures for 1916 showed: In-patients, 2161; out-patients, 43,665; and attendances, 108,432. Expenditure in 1916 exceeded £20,000, of which £19,000 have to be raised by voluntary contributions. At the end of four months' working this year the hospital is £3000 short of the sum required to pay outstanding accounts.

COLLOSOL COCAINE AND THE DURATION OF ANÆSTHESIA.

SINCE the publication in THE LANCET of April 28th of the reports of Professor W. J. Simpson, Professor R. Tanner Hewlett, and Dr. John Eyre on the experiments made with the view of testing the toxic and anæsthetic properties of collosol cocaine, several inquiries have been made by our readers on the important point of the duration of anæsthesia, to which a further report which has reached us provides an answer:—

Test of a Fresh Sample of Collosol Cocaine (1 per cent.) delivered April 25th, 1917.

University of London, King's College, Bacteriological Department. May 8th, 1917.

Toxicity Test, May 4th, 1917. Rabbit, weight 2050 grammes.
19·5 c.c. injected intravenously. No toxic effect whatever produced.

Anæsthesia Test.

I. ½ c.c. injected subcutaneously in rabbit at 2.36 P.M.
At 2.38 slightly insensitive at area of injection.
,, 2.39 quite insensitive ,, ,,
This was maintained until 2.55.
At 3.0 sensibility returning, which continued until at 3 30 sensibility had completely returned.

II. ½ c.c. dropped in two lots (i.e., ¼ c.c. each) into eye of rabbit at interval of 3 minutes—at 2.37 and 2.40 P.M.
At 2.44 eye quite insensitive.
,, 2.47 do.
,, 2.55 do.
,, 3.0 sensation returning.
,, 3.15 sensation practically returned.

W. J. SIMPSON.
R. T. HEWLETT.

Apart from the duration of anæsthesia it is noteworthy that as much as 19·5 c.c. of a 1 per cent. solution of collosol cocaine proves to be non-toxic when intravenously injected into a rabbit. Further investigations in this interesting field are being carried out.

ANKYLOSTOMIASIS IN ASSAM.

AN interim report upon an investigation into the incidence of ankylostome infection among the coolies employed in the tea-gardens of the Darjeeling district, Assam, has been recently published by Major Clayton Lane, I.M.S., in the *Indian Journal of Medical Research*. The object of the inquiry was threefold—namely, to ascertain the amount of the infection in the locality, to free those infected from the parasites, and to find out if possible what effect the existence of ankylostomiasis had upon the general health and working efficiency of the labourer. Having secured the coöperation of the managers of the tea-gardens, Major Clayton Lane proceeded, as a preliminary measure, to rouse the interest of the native workers in the investigation by means of lectures and demonstrations, illustrated by lantern slides. This he did for the purpose of inducing the coolies to permit samples of their bowel discharges to be examined microscopically for the presence or absence of the ova of the ankylostome worm. After surmounting numerous difficulties he was ultimately successful in obtaining 11,142 samples of fæces from the workers in 10 tea-gardens, from prisoners in the local jail, from members of the local police, from children attending some schools, and from inmates of the mission homes. Of the total examined 7356, or 66 per cent., were found to be infected by the hookworm, *Necator* (or *Uncinaria*) *americanus*, which is the only variety of ankylostome worm found in the locality. It may be remarked here that in spite of its name the *Necator* is widely distributed in the old world, being found in other parts of

India, e.g., Burma, while it is common in Ceylon. The Philippine Islands, tropical Africa, and North-West Rhodesia are also among its hunting grounds. Among the 11,142 samples of fæces examined 7541, or 68 per cent., were infected by *Ascaris lumbricoides*. A register was kept of the results in each instance; those persons found not to be suffering from ankylostomiasis received a certificate to that effect, and those infected received treatment which was mainly by thymol, the dose for an adult being 60 grains divided into three doses given at hourly intervals on an empty stomach. The stools were subsequently re-examined and, if necessary, a second or a third course of treatment was given to ensure freedom from the infection. As regards the attempts to estimate the effects upon bodily energy that may have followed upon the freeing of the coolie from infection, nothing very definite can as yet be stated; but the investigation is being continued and information is being collected from the managers of tea-gardens as to the amount of work now done by those cured of their worm infection as compared with what they did a year ago. The coolies themselves have expressed satisfaction with the results of their treatment in bringing to them a new feeling of energy and well-being.

MICROPSIA AND MACROPSIA.

THE latest volume of *Transactions of the Ophthalmological Society of the United Kingdom* contains a paper by Dr. S. A. K. Wilson on a symptom of not infrequent occurrence, under both physiological and pathological conditions, which presents certain features of interest. By micropsia is signified a disturbance in the visual appreciation of the apparent size of objects, whereby they seem smaller than they really are; macropsia is the term for the opposite condition. As a new word to combine both of these Dr. Wilson suggests "dysmetropsia," which may be taken to indicate defect in the visual appreciation of the measure or size of objects, whether by over-estimation or under-estimation. It is well known that dysmetropsia may occur as a transient phenomenon in fatigue states; and in the normal individual with uniocular vision alteration in the apparent size of objects can readily be demonstrated. If, one eye being closed, the other is directed on the finger placed between the eye and a printed page, the letters on the latter appear to grow smaller or larger as the finger is moved to or from the eye. Further, objects appear larger when seen through a fog while the sun and moon are apparently larger when seen at the horizon than at the zenith. There are various pathological states of the nervous system in which the phenomenon of micropsia or macropsia occurs, and Dr. Wilson has collected in his paper a number of instances from his own observation. These he has classified into two groups—viz., dysmetropsia of peripheral causation, and of central causation, the latter group being subdivided into cortical and transcortical varieties. In the first category are placed examples of the syndrome occurring in the course of tabes dorsalis, syphilitic basal meningitis, and disseminated sclerosis, where it is clear the cause of the dysmetropsia is a defect in the peripheral mechanism of accommodation. Actual retinal distortion from sarcoma of the choroid, retinitis, &c., may also have the same effect. In the second group Dr. Wilson records cases illustrating micropsia or macropsia as an aura in epilepsy, as a prominent feature in migraine, as a symptom in the course of cerebral tumour. In the transcortical group, including so-called psychical cases, he records, among others, a severe case of hysteria, the patient being a woman of 29, with hysterical ptosis and other typical hysterical symptoms. She had noticed that objects seemed much larger with the right eye than with the left, and, further, that with binocular vision the right half of objects was always much bigger than the left. Any round object, such as a ball, always appeared to bulge out on its right side. In other words, with the right eye only the condition was one of macropsia, with binocular vision of right hemimacropsia. This case in some ways resembles one described by Pierre Janet in his work on the psychoneuroses. Dr. F. W. Mott has reported the case of a Canadian officer suffering from shell shock who complained of seeing everything greatly magnified—his bandolier of cartridges looked as large as a pom-pom belt. Organic cases also, however, may show this dysmetropsia as a transcortical or psychical symptom, as in one under Dr. Wilson's care where the patient was a member of the medical profession and his observation therefore of enhanced value. This patient suffered from a cerebral tumour of the right occipito-parietal region, and among his symptoms were visual hallucinations of a macropsic nature; he thought he saw objects in front of him which were not really there, and they were apparently "very large and very near." It appears, then, that the phenomenon of dysmetropsia may be caused by disturbance of function on any of the levels of nervous function described by the late Dr. Hughlings Jackson as the lowest, middle, and highest levels—i.e., peripheral or subcortical, cortical, and transcortical or psychical levels. In his paper Dr. Wilson gives a suggested explanation of the pathogenesis of the condition and discusses the various factors that may be implicated.

THE MEDICAL INSURANCE AGENCY.

AT a meeting of the committee of the Medical Insurance Agency held last week, at the offices of the British Medical Association, the chairman, Dr. G. E. Haslip, presented the audited financial statement for the year 1916.

The annual statement showed that, in spite of the war, the surplus available for medical benevolent purposes had reached the sum of £841, compared with £798 in the previous year. The Agency was able during the year to distribute £230 to the Royal Medical Benevolent Fund, £160 to the Royal Medical Benevolent Fund Guild, £145 to Epsom College Benevolent Fund, £50 to the R.A.M.C. Officers' Benevolent Fund, £50 to the Auxiliary R.A.M.C. Fund (Officers' Benevolent Branch), £30 to the Royal Medical Benevolent Fund Society of Ireland, £25 to THE LANCET Special Fund, and £15 to the Royal St. Anne's School. In addition to these amounts, last week the committee was able to make an interim distribution on the current year of £200 to the Royal Medical Benevolent Fund, £100 to the Royal Medical Benevolent Fund Guild, £150 to Epsom College Benevolent Fund, and £50 to the Royal St. Anne's School.

Dr. Haslip mentioned in his report that since its formation the Agency had been able to devote a total sum of £2805 to medical benevolence, while the individuals insuring had received rebates amounting in the aggregate to £5300. This may be regarded as a highly satisfactory financial position and one which demonstrates the good work which the Agency is accomplishing for the medical profession. By insuring through the Medical Insurance Agency favourable premiums are obtained as well as benefit conferred on medical charities. The secretary of the Agency is Mr. Guy Elliston, 429, Strand, W.C. 2.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM: ANNUAL CONGRESS.

THE Annual Congress of this Society was held on May 3rd to 5th inclusive, under the presidency of Mr. E. TREACHER COLLINS. The general discussions took place at the house of the Royal Society of Medicine, a debate on "Employment of the Blind" was held at St. Dunstan's, Regent's Park, and the clinical cases were inspected and discussed at the Royal London Ophthalmic Hospital, City-road.

At the opening meeting on Thursday morning the PRESIDENT referred to the great loss which the society and ophthalmology had sustained by the death of Mr. Walter H. Jessop, a former President and a most enthusiastic worker in the specialty. In his introductory address he dealt at length with the subject "The Sequelæ of Hypotony." The following is a brief statement of his conclusions:—

I. That hypotony may occur in connexion with several different affections of the eye, and the sequelæ to which it gives rise may be considered apart from the affection causing it.

II. That the sequelæ of hypotony vary in different cases according to the chamber (the aqueous or the vitreous) in which the pressure is most reduced, and according to its degree, duration, and rapidity of onset.

III. That the sequelæ of hypotony may be classified as follows:—1. Those due to relaxation of tissues usually kept taut: (*a*) wrinkling of the anterior elastic lamina of the cornea, producing superficial double-contoured lines; (*b*) wrinkling of the posterior elastic lamina of the cornea and layers of the substantia propria immediately adjacent to it, producing deep-seated striated opacities; (*c*) thickening of the sclerotic and the production of puckers in it behind the insertions of the recti muscles; (*d*) wrinkling of the elastic lamina of the choroid, and heaping up of the pigment epithelium on its inner surface where the folds are deep; and (*e*) displacement forwards of the lens and slackening of its suspensory ligament, both of which tend to increase the refraction of the eye. 2. Those due to production of relatively higher blood pressure compared to intra-ocular pressure than exists under normal conditions: (*a*) In the choroidal veins the normal excretion of lymph through them is arrested, and, instead, an exudation of lymph takes place, giving rise to detachment of ciliary body and choroid; (*b*) in the veins of the iris the normal excretion of the aqueous humour through them is arrested, and, instead, an exudation of lymph into the anterior chamber takes place, this exudation altering the normal consistency of the aqueous by increasing its percentage of proteids and rendering it spontaneously coagulable; (*c*) in the capillary vessels of the ciliary body the secreting function of that structure is quickened, and an exudation of lymph takes place, the albuminous constituents of which, in a rabbit's eye, being unable to permeate the epithelial lining of the part, raises it up in the form of vesicles; (*d*) in the capillary vessels of the choroid the normal exudation of lymph is stimulated, which, if it permeates the pigment epithelium, may collect beneath the retina, causing detachment of that membrane; and (*e*) in the retinal vessels of the optic disc the normal excretion of fluid from the vitreous is arrested, and an exudation of lymph into the head of the optic nerve takes place, giving rise to the appearances of choked disc.

The paper was discussed by Sir ANDERSON CRITCHETT, Mr. S. JOHNSON TAYLOR, and Mr. J. HERBERT PARSONS.

Lieut.-Col. R. H. ELLIOT, discussing the foregoing address, said that some years ago he pointed out that a condition of hypotony might exist for many months, or even for years, in patients who had undergone sclero-corneal trephining without any evidence that the eyes had suffered thereby. Others, including Mr. Treacher Collins, had confirmed the observation. Because cataract followed, or was considered to follow, the operation for glaucoma, it was not necessarily the result of the hypotony produced, or even of the operation itself. Cataract might precede glaucoma, and, under the conditions met with in high-tension eyes, it was possible for the lens opacities to be overlooked at the time. He thought there were other conditions besides a direct wound of the lens during operation which might determine the formation of a cataract. He had been able to keep in touch with cases for six years, and was able to say it did not necessarily cause opacities of the lens; indeed, it was open to question whether it ever did. The expectation that an artificial hypotony would lead to serious changes in the eye was largely due to a confusion of ideas. It was very erroneous to consider the condition of the contents of the eye as though the problem were one of hydrostatics; it was really one of hydrodynamics. The manometer was far too coarse an instrument to give reliable indications of the minute differences of pressure which certainly existed in the various chambers of the eye. The most helpful part of the President's contribution was that which referred to the transudation of serum into the anterior chamber from the surface of the iris, the posterior chamber remaining free of the pathologic exudate. He agreed as to the transitory tendency towards myopia after trephining: he had often noted it; he had seen as much as 2½ diopters of myopia within a fortnight of the procedure. As the flap consolidated the chamber deepened, the lens system receded, and the myopia disappeared, the eye gradually returning to its original state of refraction.

The PRESIDENT replied.

Mr. A. HILL GRIFFITH read a paper on Transmitted Glioma of the Retina.

Captain W. WALLACE contributed a paper on Conditions Affecting the Standard of Vision in the Army. He urged that in aiming at efficiency in this matter the standard of the patient, and especially his mental attitude, must not be disregarded. He discussed the changed visual standards set up by the Army Council, which, he believed, had not resulted in any considerable transfer into Class A of those formerly in a lower category. For example, of 723 cases only 46 were raised from B to A, while 11 went from A to B. He supported his views by a carefully compiled table.

The discussion revealed conclusions at variance with those of the author, and in the end a resolution was agreed to in regard to the visual standards in the Army.

Captain R. R. CRUISE read a paper on Protection of the Eye in Warfare. He said it was hoped that the measure of protection against injuries to the head afforded by the steel helmet would find a parallel, in the case of the eye, in the visor which he had designed, and which the War Office had accepted and adopted. This visor was now on extensive trial. From the point of view of protection, the injuries may be divided into two classes: (*a*) preventable, and (*b*) non-preventable. The simplest instances of the first class were those in which a small shell splinter penetrated the globe, and of the second category a bullet traversing both orbits. To obtain an accurate conception of the extent of the preventable class, a large number of cases must be carefully examined. In some cases it was difficult to know into which category to place them. Among the definitely preventable were cases in which the cornea was incised, the iris prolapsed, and a septic panophthalmitis ensued, cases in which a foreign body had had sufficient energy to penetrate the globe but not to pass out of it. In the same class also were contusions of the globe producing a varied and common picture of dislocated lens, traumatic cataract, irido-dialysis, intraocular hæmorrhage, and retinal lesions. He had been surprised at the relatively few cases of detachment of the retina which his war experience had included. Morex and Moreau, of Paris, estimated that 54 per cent. of casualties to eyes in a series of 488 cases of injury caused by shell, grenade, or bomb were produced by small particles, the condition being that 50 per cent. of all eye injuries could be prevented by some sort of gauze shield. From the examination of a very large number of cases of eye injury during the war Captain Cruise found that 58 per cent. of them were preventable; 42 per cent. non-preventable. The visor consists of a transparent mesh of steel rings so closely linked together that only the most minute particles could pass through its meshes, and then only if the impact occurred at right angles to the plane of the surface. The visor is attached to the helmet, and when not required is easily thrown on to the brim of the helmet and as easily lowered again into position when required. The links were chemically treated to render them rust-proof.

The society passed the following resolution:—

The Ophthalmological Society of the United Kingdom, having examined the steel visor designed by Captain Cruise, has every reason for believing that it would prevent at least 50 per cent. of the eye injuries received in warfare. The visor has received the strong approval of ophthalmic surgeons in the field and at home. This society begs respectfully to urge that its production should be expedited, and that its application and method of use should be placed under the supervision and control of a competent authority.

Mr. J. GRAY CLEGG read a paper on "Sclerocorneal Trephining for Hypertension, with Results of some 250 Cases."

(*To be concluded.*)

THE RECENT VACCINATION ORDER.—The Association of Public Vaccinators of England and Wales has been in communication with the Local Government Board regarding the scope of the recent Order permitting medical officers of health to vaccinate small-pox contacts. The reply of the Assistant Secretary to the Board, dated April 25th, runs as follows:—

I am directed by the President of the Local Government Board to advert to your letter of the 30th ultimo and to state that the object of the Public Health (Small-pox Prevention) Regulations, 1917, is to empower a medical officer of health to vaccinate or revaccinate contacts with cases of small-pox. The Board anticipate that the need for this will only arise when the services of the public vaccinator are not immediately available. In ordinary circumstances the operations should be performed by the public vaccinator as hitherto.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Society of Medical Radiology.

THE Under Secretary of State for the Service of Health recently presided at a meeting of this society. M. Ledoux-Lebard contributed a study of practical methods at the front and at the base. He agrees with Ombrédanne that extraction of foreign bodies by the aid of intermittent screen control is now a possibility, given conditions allowing the surgeon sufficient latitude for operating without exposing him dangerously to the rays. But whatever technique may be adopted any difficult exploratory operation should be performed on a radiological table. Of this there seems to be no doubt. M. Aubourg and M. Barret reviewed the various types of radiological installation in the Army, and asked for the radiologist to be given the choice of exploratory method for establishing his diagnosis, alleging a great saving of plates by this means. M. Rechou emphasised the large place now held by radiotherapy in the treatment of gunshot wounds. M. Belot described a very exact procedure demanding the minimum of special appliances, while allowing the ophthalmologist to locate a foreign body precisely by means of four radiographic plates. M. Béclère stressed the necessity of confining the direction of radiological services to doctors, requiring, as it does, a combination of anatomical, physiological, pathological and chemical knowledge which only medical men possess. Finally, M. Delherm and M. Kindberg demonstrated the advantages of radio-diagnosis in suspected pulmonary tuberculosis among soldiers. Sometimes the symptoms may be shown by means of the rays to be of purely functional origin, in other cases early diagnosis is rendered possible, and in a third group the pulmonary origin of obscure symptoms is established thereby. The help of the radiologist is likely to result in great benefit to Medical Boards.

Superiority of Agricultural Work to Physico-Therapy.

At the Academy of Sciences M. Bergonié related the result of comparative observations extending over 30 months showing the superiority of agricultural work, medically prescribed and supervised, over the physical institutional treatment of the results of gunshot wounds. This is specially the case with men formerly agricultural labourers, who naturally return with readiness to their former habits of fresh-air life, and in so doing recover almost unconsciously the movements to which they have been accustomed since early youth. Fatigue is diminished thereby, inasmuch as attention is not continuously in demand; it is the reflex arc, physiologically almost inaccessible to fatigue, that is brought into play. M. Bergonié finds agricultural work applicable to all varieties of disability, granted that the routine is prescribed and supervised by a medical man. The results of this functional re-education in the Bordeaux district have been most gratifying from the point of view of both moral and physical fitness. Naturally the treatment has a wider application during fine weather than in autumn or winter.

The War-time Pot-belly.

M. Dénéchau and M. Mattrais recently drew attention at the Medical Society of the Hospitals to a singular morbid condition observed by them on several occasions, manifesting itself in a peculiar deformation of the abdomen associated with gastro-intestinal disturbance. The subjects are tired persons complaining of colitis, vomiting, alternate constipation and diarrhœa, with emaciation; the abdomen becomes distended and prominent, walking is impeded, and the presence of Pott's disease occurs to the mind. The resemblance to a seven or eight months pregnancy is striking, but the size of the abdomen varies somewhat in different positions, especially on lying down, and the volume is reducible to some extent by vigorous flexion of the thighs. The poor general condition of the patients may also raise a suspicion of chronic peritonitis, and discharge be recommended on this account. Of M. Dénéchau's 18 cases, 5 were already under consideration for discharge. The deformation was, however, shown to be of a motor nature, partly voluntary or subconscious, resulting from depression of the diaphragm—a fact which could readily be established by radioscopy. The crises of colitis and the occasional aerophagia from which these patients suffer give rise to auto-suggestion of grave abdominal mischief.

The Administration of Quinine in Syphilis.

In his malarial clinic at the Pantheon Hospital, M. Jeanselme has collected a number of observations having the absolute value of laboratory experiments. At this hospital patients are submitted to intensive quinine treatment, some of them having received as much as 40 grammes of the hydrochlorate. A few of these patients developed syphilis during quinine treatment, the exact day of infection being ascertainable; the disease was found to run its course in precisely the same way and in the same time as in cases not under the influence of quinine. It follows that in syphilis quinine has neither a preventive nor a curative action.

A Gastric Hair-ball in a Girl.

Dr. Dauriac aroused keen interest at the Academy of Medicine last month by communicating the case of a girl aged 13 whose stomach was entirely filled by an enormous bundle of hair of the same consistency as those sometimes found in horses. The child had contracted in infancy the strange habit of biting and swallowing locks of her own hair. This mass occupied the lumen of the stomach and the first part of the duodenum. Digestion was defective and the child was becoming emaciated. Dr. Dauriac excised the stomach with its contents, the nature of which was not suspected. The end of the œsophagus, fortunately much elongated, was sutured to the pylorus, the child recovering rapidly from the operation and regaining full digestive powers.

THE CONTROL OF VENEREAL DISEASES.

A Comparison of English and American Methods of Venereal Control.

THE *Journal of the American Public Health Association* for April, contains an editorial article on the prevention and cure of venereal diseases, in the course of which, after describing the Local Government Board Regulations, the writer adds:—

> This remarkably thorough organisation for dealing with social diseases is the outcome of the report of the Royal Commission, which contains statistics and facts regarding the situation, full of interest and illustrative not more of the conservative way in which legislation is undertaken in Great Britain in matters affecting the liberty of the citizen than of the scientific and thorough manner in which legislation when once enacted is put in force. The elevated ideas along social lines which prevail in Parliament are well illustrated when they accept the findings of a scientific commission as a sufficient guide to them in passing legislation of so drastic a character as that in recent Acts.
>
> It is probably true that on the American continent similar legislation is more readily obtained when public agitation has been worked up than in England; but the practical difficulties in its enforcement are usually found not more in the refusal of the general public to submit to drastic regulations than in the extremely varied character of our administrative machinery. It is true that in most States and Provinces local Boards of Health are appointed, while in probably all such the boards in cities and towns where hospitals are located have fairly adequate public health by-laws. What is, however, altogether too prevalent is the evil of temporary political appointments of health officers with, in consequence, tenures of office unfortunately very uncertain.

The article concludes by foreshadowing for the United States legislation of an adequate character, such as that recently passed in this country, but including compulsory notification and supervision of all patients until completion of treatment. In this way "the first real steps in advance in the solution of this, the most difficult of all public health problems, will have been taken."

Dr. R. R. Rentoul calls our attention to penal clauses in regard to venereal diseases which appear in the legislature of various North American States, e.g.:—

> State of Oregon, Feb. 28th, 1913.—S. 1. Applicant for permit to re-marry must file a certificate from an authorised physician, made under oath, that the male applicant is free from contagious or infectious venereal disease. S. 2. Physician making false statement shall lose his diploma. S. 3. Fee for doctor's certificate 2 50 dols.
>
> North Dakota, 1913.—S. 1. No woman under the age of 45, or man of any age, except he marry a woman over 45, either of whom is ..... afflicted with pulmonary tuberculosis in its advanced stage, or of any contagious venereal disease, shall hereafter inter-marry or marry any other person within this State. S. 2. Penal for clergyman to join in marriage such persons. S. 5. Fee for doctor's certificate 2 dols. S. 6. Fine for illegally joining in marriage 50 to 500 dols. or imprisonment for 30 days.
>
> State of Pennsylvania, 1913.—S. 1. No permit to marry if either of the contracting parties is afflicted with a transmissible disease. S. 4. Applicant may appeal to a court free of expenses.
>
> State of Michigan, 1905.—S. 6. No insane person, idiot, imbecile, or person who has been afflicted with syphilis or gonorrhœa, and has not been cured of the same, shall be capable of contracting marriage. Certificate of being cured must be signed by two qualified physicians. Anyone aiding or assisting such to marry may be fined up to 1000 dols., or to imprisonment up to five years.

Salvarsan or Neosalvarsan?

The relative value of the various organic preparations of arsenic at present on the market is by no means firmly established. In the *British Medical Journal* of May 5th Lieutenant-Colonel L. W. Harrison and his coadjutors at the Rochester Row Military Hospital, Major C. F. White and Mr. C. H. Mills, emphasise the obvious difficulties which seriously limit the intravenous administration of these preparations, and the great advantage of the hypodermic method if rendered painless and proved to be as effective as the other. After investigating the Wassermann reaction in a series of more than 100 cases treated by means of the various preparations, some administered intravenously, others hypodermically, they conclude: (1) The intramuscular or subcutaneous injection of neosalvarsan, novarsenobenzol, or novarsenobillon is superior in immediate therapeutic effect to that of the intravenous injection of salvarsan, kharsivan, arsenobenzol, or arsenobillon; (2) spirochætes disappear from syphilitic lesions just as rapidly after the first intramuscular as after the first intravenous injection, and the Wassermann reaction is more quickly influenced; (3) solution of the dose of neosalvarsan in 1 c.c. of 4 per cent. stovaine and emulsion in creo-camph cream eliminates discomfort sufficiently to make the intramuscular injection of neosalvarsan practicable for routine use. This result, if confirmed, will much simplify the work of the venereal treatment centres as well as that of the practitioner called on to administer organic arsenic.

Routine Treatment of Syphilis at the Hôpital Broca, Paris.

Military needs require a short, intensive treatment of syphilis for the soldier in order to send him back as soon as possible to his place at the front. In the *Paris médical* of May 5th Dr. Hudelo, physician to the Hôpital Broca, describes the routine treatment, lasting 40 days, adopted in the hospital since the outbreak of the war. Nine injections of 0·3–0·9 gm. of novarsenobenzol (4–5 gm. in all) are given at intervals of five days interspersed with 20 injections each of 0·01 gm. mercuric cyanide. In every case the patient left the hospital with a negative Wassermann reaction. On his discharge-sheet is written an instruction to receive further mercurial treatment, by pill or injection, after an interval of not more than two months. Dr. Hudelo writes:

> We hope, by this association of arsenic and mercury, that the spirochætes put out of action but not killed by the arsenobenzol, which disappears from the system in 48 hours, and still maintaining a stand in some corners of the organism will succumb completely to the spirochæticidal action of the mercury. We note with pleasure that a method identical with that here suggested has been adopted in military practice, amongst others, by Favre and Longin, Pautrier, Goubeau, Pasteau and Mallein, Ravaut, and Thiblerge.

The British Journal of Dermatology and Syphilis.

The *British Journal of Dermatology* has existed for 28 years, and during that long period has done a large amount of excellent work in the province of dermatology. It has now been decided to change its title by the addition of "Syphilis," in view of the prominent place that syphilis holds in dermatological work. All who have had much experience in the diagnosis and treatment of diseases of the skin know that syphilitic rashes are frequently unrecognised, and the results of these errors of diagnosis are deplorable. If syphilis is recognised and treated in the secondary stage when skin manifestations are mostly seen, the spread of the disease would be greatly diminished and those more serious and later results would be rendered impossible. We therefore welcome the change in the title of this important journal, for it emphasises the need for syphilis to be recognised and treated while it affects mainly the skin and before it has had time to establish itself as a constitutional affection.

Courses of Instruction.

A course of instruction in the clinical pathology of venereal diseases will be given by Dr. J. Eyre to practitioners, post-graduates, and students, in the pathological theatre of Guy's Hospital Medical School, at 5 P.M. on May 21st, 23rd, 24th, and 25th. Laboratory demonstrations in the bacteriological laboratory follow each lecture at 6 P.M. Members of the medical profession to be admitted on presentation of their cards.

Enlightenment Campaign.

The acting medical officer of health of the borough of Deptford, Dr. Murdoch Macdonald, has arranged or a conference of the citizens representing the various interests —municipal, industrial, educational, social, and religious— in the borough of Deptford, to be held in the Council Chamber at the Town Hall on Wednesday, May 23rd, at 8 P.M., when Mr. A. R. Turner and Mrs. Gotto will outline the work of the National Council for the Prevention of Venereal Diseases.

Major F. W. Mott, F.R.S., delivered an illustrated lecture on the Pathology of Venereal Disease at the Royal Institute of Public Health on May 9th. He emphasised the fact that pathology had now done its work in finding the cause of venereal diseases and the means of remedying them, and that it was for the State, acting on this work, to take such measures as were necessary to prevent, or failing that to cure, venereal diseases.

NATIONAL HEALTH INSURANCE.

The Public and Panel Practice in London.

RECENT circulars, numbered D 8, D 9, have been addressed to various bodies interested in the administration of National Insurance, and a Subcommittee of the Panel Committee for London has drafted a memorandum upon them, which has been adopted by the Committee and which is of interest because of its broad outlook. Recognising itself as only competent to speak for members of the medical profession upon the panel in London, but at the same time representing a body of 1500 such practitioners, the Subcommittee has been able to compile a series of notes and suggestions of a very varied character. Some of the questions are not such as medical men directly engaged upon insurance work can answer authoritatively, but it is all to the good that medical attention should be drawn to them. For example, the general feeling of insured persons towards insurance and the medical benefit provided under it is a matter deserving the notice of a busy panel practitioner, but for the most part his time is so fully occupied in attending to his patients' illnesses that their opinions on panel practice at large may not interest him. His hours of work and his banking account may afford him the impression that his own efforts are appreciated, or otherwise, but that is an individual matter. According to the memorandum of the London Panel Committee, he is likely to be told by his patients about administrative difficulties, such as delay in the payment of sickness benefit, or in providing medical cards, if he shows himself sympathetic, and this he should certainly be. This would seem to suggest that the insured person may be more prone to grumble, whether justly or not, at the shortcomings of those engaged on administration when in conversation with the medical man, and to ventilate any grievance against his medical attendant in communications with officials of his Approved Society, or with the Insurance Committee. In any case the small number of applications by insured persons in London to make their own arrangements with medical practitioners outside the panel is evidence of general satisfaction with the attendance provided by those within it.

With reference to the general feeling of the medical profession in London towards insurance practice, the Subcommittee believes that the majority of those engaged in it find the conditions preferable to those formerly prevailing in club practice or private practice in poor districts. It does not go further than that. As to the conditions which would bring into panel practice more of those general practitioners who, chiefly in wealthier areas, now decline to engage in it, the Subcommittee offers no precise opinion. It has suggested, however, certain improvements which it is inclined to believe would bring in a considerable proportion of those who now stand aloof. In any case, however, it has been found that an overwhelming majority of panel practitioners in the metropolis prefer the present conditions to the prospects offered by a whole-time salaried service, for which, by the way, no definite scheme has ever been put forward for consideration by anyone in a position to do so with authority. The memorandum summarises the principal reasons upon which the preference referred to is based. The suggestion may be added that at the present time a very large proportion of the medical profession is now gaining experience as to some, at least, of the drawbacks or advantages of service under a controlling authority.

Service under the War Office, whether at home or abroad, at the present date may differ widely from service under a civil authority in time of peace, but the mere experience of service as such is likely to have done much in shaping the opinions of those most concerned as to the desirability of the revolutionary change which a "service" implies. All these general topics affecting medical practitioners on the London panel have their bearing on the question of the remuneration, summarised in the question, "If a panel practice and the remuneration derived from it were the sole work and pay of a practitioner, would such a practice of average size enable him to maintain a social position suitable to his professional status?" The memorandum replies by calling attention to the fact that panel practice is usually combined with other forms of practice, but as to the question as it stands expresses the view that the remuneration there referred to is inadequate, having regard to the length and cost of the period of education, and "the desirability of a professional man being able to educate some of his children to follow his own calling." It might have said that the maintaining of his social position by a professional man must include the bringing up of all the members of a fair-sized family so as to enable them to occupy a position equal to that of their father. This, we suggest, would constitute a problem of some difficulty for a member of the medical profession in the metropolitan area earning only the income afforded by a panel practice of "average size." It emerges from the memorandum that the question of remuneration will be one of the first importance if ever any statesman proposes a concrete scheme of salaried service. If that remuneration is to be based upon the acceptance of panel conditions by panel practitioners under pre-war conditions it is not likely to prove satisfactory to its proposed recipients. As to this the memorandum contains a timely reminder in a note which calls attention to the varying economic and other conditions due to the war—to rising costs of commodities and of services which may never resume their former rates, and to the lowered comparative value of salaries and fees. With these altered conditions affecting all professional life in the future there must be included for the consideration of medical practitioners the grave problem of the disabilities of soldiers, sailors, and civilian workers likely to be found due to the ordeal through which the country is passing. The above are, as we have indicated, some of the general questions dealt with in the memorandum of the Panel Committee of London. More particular topics have to be discussed in the light of conditions prevailing in and affecting particular localities.

URBAN VITAL STATISTICS.

(Week ended May 12th, 1917.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 17,000,000 persons, the annual rate of mortality was 15·3, against rates declining from 18·5 to 15·7 per 1000 in the four preceding weeks. In London, with a population exceeding 4,000,000 persons, the death-rate was 15·4 per 1000, and was equal to that recorded in the previous week; among the remaining towns the rates ranged from 5·4 in Acton, 6·7 in Eastbourne, and 7·5 in Barrow-in-Furness and in West Hartlepool, to 23·6 in Halifax, 23·7 in Sunderland, and 29·8 in Middlesbrough. The principal epidemic diseases caused 419 deaths, which corresponded to an annual rate of 1·3 per 1000, and included 252 from measles, 54 from whooping-cough, 47 from infantile diarrhœa, 45 from diphtheria, 12 from enteric fever, and 9 from scarlet fever. The deaths from measles were 34 below the average in the previous weeks, and caused the highest annual death-rates of 3·1 in Dudley, 3·2 in Salford, 3·9 in Sunderland, and 4·8 in South Shields. The 707 cases of scarlet fever and 1179 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 32 and 24 below the numbers remaining at the end of the previous week. Of the 4936 deaths from all causes in the 96 towns, 152 resulted from violence. The causes of 39 deaths were uncertified, of which 8 were registered in Birmingham, 5 in Liverpool, and 3 each in Bury, Manchester, and South Shields, but not one in London.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual death-rate was equal to 15·9, against 18·4 and 17·2 per 1000 in the two preceding weeks. The 339 deaths in Glasgow corresponded to an annual rate of 15·8 per 1000, and included 41 from measles, 36 from whooping-cough, 6 from infantile diarrhœa, 3 from diphtheria, and 1 from scarlet fever. The 107 deaths in Edinburgh were equal to an annual rate of 16·8 per 1000, and included 15 from whooping-cough, 11 from measles, and 1 from scarlet fever.

Irish Towns.—The 155 deaths in Dublin were equal to a rate of 20·3, or 1·7 per 1000 less than that recorded in the previous week, and included 6 from measles, 3 each from enteric fever and whooping-cough, and 1 each from diphtheria and infantile diarrhœa. The 132 deaths in Belfast corresponded to an annual rate of 17·5 per 1000, and included 4 from infantile diarrhœa, 3 from measles, 2 from enteric fever, and 1 each from scarlet fever and diphtheria.

Obituary.

MARC ARMAND RUFFER, KT., C.M.G., M.A., M.D. OXON., F.L.S.,

PRESIDENT OF THE SANITARY COUNCIL OF EGYPT.

Sir Armand Ruffer, who died at sea as he was returning to Egypt from Salonika, where he had gone to reorganise the sanitary service for the Greek Provisional Government, was one of the great medical administrators of his time.

Marc Armand Ruffer was born at Lyon in 1859, son of the late Baron Alphonse Jacques de Ruffer. His mother was German, and the son was therefore brought up with an intimate knowledge of three European languages. He was educated at Brasenose College, Oxford, and University College, London, taking his Arts degree in 1883 and obtaining his medical qualification four years later. From the first interested in pathological work he became a pupil of Pasteur and Metchnikow at the famous Institute in Paris, and on returning to London continued to work at the problems of phagocytosis, which were then of new and surpassing interest. His first important article was contributed in 1890 to the *Quarterly Journal of Microscopical Science*, and in the same year he read a paper at the annual meeting of the British Medical Association on the destruction of micro-organisms during the process of inflammation. In these papers clear expression was given to the conception of inflammation as a protective mechanism serving a useful purpose against infection, and in one of them Ruffer described the diphtheritic membrane as a battlefield in which amœboid cells contended with the pathogenic microbes of the disease. His further work on phagocytosis in the intestinal canal has not yet received the recognition which it deserves. It was at this time that Ruffer became the first director of the British Institute of Preventive Medicine, where he was assisted by Professor H. G. Plimmer. At Metchnikow's suggestion the two pathologists turned their attention to cancer, and they succeeded in establishing the fact that the intracellular objects seen in cancer cells did not resemble any known form of cellular degeneration. The last work Ruffer carried out at the Institute was on diphtheria, for which the antitoxic serum was then a new discovery. The preparation and testing of the serum was a laborious and dangerous task, both Ruffer and Plimmer falling victims to the disease, Ruffer himself suffering so severely from diphtheritic paralysis that he resigned his directorship of the Institute and sought health on a visit to Egypt.

In 1896 Ruffer was appointed professor of pathology in the Medical School of Cairo in succession to Dr. Kaufmann, and here his latent administrative ability served him in good stead. He started to reorganise the school, collecting around him a staff of able men to carry on his traditions. His success was so evident that two years later he was offered and accepted the presidency of the International Sanitary, Maritime, and Quarantine Council of Egypt, which he retained throughout his life. The organisation which freed Egypt from cholera began with the building of stations on the pilgrim routes, especially at Tor on the Red Sea, where the director personally inspected the pilgrims, letting no suspicious case pass through. Without special knowledge of Arabic his linguistic capacity, combined with the exercise of great tact, enabled him to surmount the difficulties of the situation. In his administrative work he was upheld throughout by the late Lord Cromer, and later by the late Lord Kitchener, who both had the fullest confidence in the measures he proposed. His appointment on the Indian Plague Commission took him away from Egypt for a time, and the volumes of the Commission's reports may still be read with profit. To Ruffer was due the increasing recognition of the value of Haffkine's work.

Ruffer took the greatest interest in antiquarian work for which Egypt provided him ample opportunity. He made a careful investigation of the mummies of the eighteenth, nineteenth, and twentieth dynasties in the Hearst collection at Cairo, finding in them a great variety of grave pathological phenomena, including arterio-sclerosis, tuberculosis, lung disease, anthracosis, and multiple abscess of the kidney. In the morbid lesions micro-organisms were found still recognisable by their staining reactions, among them the tubercle bacillus. The aorta of Rameses II. which he sent to London

was examined by Professor Plimmer and found to show marked atheromatous change. Ruffer concluded that arterial lesions were as frequent 3000 years ago in Egypt as at the present time, and were even then due to the stress and responsibility of civilised life rather than of toxic origin. A study of the artistic productions of ancient Egypt enabled Ruffer to analyse the prevailing diseases of even earlier times, 5000 years or more ago. Achondroplasia, Pott's disease, talipes were recognised with certainty, probably also rickets. A volume of antiquarian studies likely to be of surpassing interest was ready for the press, but unfortunately prevented by the conditions of war from appearing.

At the outbreak of war Ruffer was appointed head of the Red Cross in Egypt and did a large amount of useful work in this connexion. After completely organising the means at his disposal he felt free to accept an invitation from the Greek Provisional Government to undertake the sanitary reorganisation in the Salonika district. His last letter records the fact that in spite of grave difficulties and discouragement good progress had been made in this work. It was during his return to Egypt that his lamented death occurred. Many honours fell to his share, among them the Grand Order of Medjidie and the Grand Order of Osmanieh in Egypt. He was a Commander of the Order of St. Saviour of Greece, St. Anne of Russia, and of the Cross of Italy, and an Officer of the Legion of Honour. His Companionship of the Order of St. Michael and St. George was granted in 1905 and supplemented by a Knighthood in 1916. Ruffer was a man of deep culture in the best sense. With his linguistic powers and knowledge of men he was peculiarly fitted to be a sanitary administrator of a great dependency. He was also a keen musician with technical mastery of the violoncello. Sir Armand Ruffer married Alice Mary, eldest daughter of the late Captain Greenfield, R.A., and is survived by his widow and three daughters.

PROFESSOR LANDOUZY,

DEAN OF THE FACULTY OF MEDICINE, PARIS.

WITH the death of Professor Landouzy in Paris, at the age of 72 years, on May 10th, after a long illness, the Paris Faculty of Medicine has lost its senior and most distinguished member. Louis Théophile Joseph Landouzy was born at Rheims in 1845, the son and grandson of medical men. Beginning his studies in the place of his birth, he went to Paris in 1867 to complete them, becoming hospital resident in 1870, and steadily ascending the professional ladder until his appointment as physician to the Hospital Laennec in 1890. Three years after this he accepted the chair of therapeutics at the Faculty of Medicine in Paris, bringing with it the membership of the Academy of Medicine. In 1907 he was chosen by the Faculty to be its dean, and in 1912 he was elected a member of the Institute. His most recent honour was the award of a gold medal for his work on infectious diseases by the Ministry of the Interior.

Landouzy had long become one of the familiar figures of contemporary medicine both in France and abroad. Endowed with a great capacity for work associated with remarkable physical activity he accomplished a very large amount of scientific work bearing on a variety of important questions. With Déjerine he described the special type of facio-scapulo-humeral myopathy which is now associated with both their names. But it is in connexion with tuberculosis that his name will be best remembered. The pathology of the lungs owes to him important researches, notably on primary tuberculosis of the pleura. He first described in 1883 a type of acute tuberculosis which he characterised as *fièvre bacillaire non-granulique à forme typhoïde*, or more briefly later as *typho-bacillose*, in which the ordinary morbid lesions of tuberculosis failed to make their appearance. More recently, in the *Presse médicale* of April 21st, 1906, he described a flexure of the little finger as *camptodactylie* occurring in tuberculous subjects. The little finger of a patient, he said, "tells his past, shows his temperament, and foretells his future." Later still he showed that the serum from the lesions of erythema nodosum produced tuberculosis when injected into guinea-pigs. In opposition to Calmette and others he upheld the origin of laryngeal tuberculosis by direct surface-infection. In the struggle against tuberculosis as a social disease Landouzy was ever to the front. He was delegate to the several international congresses on tuberculosis, and at Washington in 1908 expressed the belief that the centenary of Pasteur would witness the final extinction of tuberculosis. If he had lived to complete it, his last work would have been devoted to the organisation of an antituberculosis campaign in the Army and to the invaliding of the tuberculous soldier.

Two qualities in Landouzy which contributed specially to his success were his great facility in physical examination and an unusual clearness of verbal exposition. The combination made him a really great clinical teacher, a fact which Paris students did not forget even when his ruling as dean ran counter to their inclinations. He was devoted to his pupils, showing himself always a sure and considerate friend to them, an example of goodwill and approachableness. He organised travel studies to the French thermal stations, conducting them himself for a dozen years. He was present in London at the last International Medical Congress of 1913, when he read a paper on thermal treatment and spoke as the official delegate at the dinner given by Lord Beauchamp on behalf of the British Government. During the last winter his health had been very variable, largely due to the extra work which he had taken upon himself in the charge of a military clinic at the Lycée Buffon in addition to his ordinary occupations. He had recently undergone two surgical operations and death was due to an attack of uræmia. He leaves behind him regret on the part of all who knew him.

HENRY WILLIAM WILLIAMS, M.D., C.M. ABERD.

Dr. H. W. Williams, whose death has occurred at the village of Guilsborough, Northants, was 81 years of age, and had been for more than 30 years actively associated with the Salvation Army. Born in 1836 and educated at Aberdeen University, Queen's College, Birmingham, and Anderson College, Glasgow, he was for a long time on the active staff of two London hospitals, the Western Skin Hospital and the Margaret-street Hospital for Consumption, to both of which he was at the time of his death senior consulting physician. He was one of the founders of the British Medical Temperance Association and a vice-president of the Society for the Study of Inebriety. Dr. Williams was an ardent upholder of the legal rights of the medical profession against the quack and impostor, contributing on the subject to our columns at the time of the Medical Acts Amendment Bill of 1867. Joining the Salvation Army in 1885, he held for 27 years the position of honorary director of the medical department at the International Headquarters in Queen Victoria-street, London, with the rank of lieutenant-colonel in the organisation.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Queen Anne's Gate Buildings, Westminster, on May 10th, with Sir Francis H. Champneys in the chair. A letter was considered from the National Association for the Prevention of Infant Mortality and for the Welfare of Infancy transmitting a copy of a draft circular prepared jointly by the Midwives Institute and the Committee of the Association, with the view of assisting practising midwives in promoting breast-feeding, and expressing the hope that permission may be given for the publication of the circular with an expression of the approval of the Board. The Board decided that the reply be that the Board gives its general approval to the circular of the National Association for the Prevention of Infant Mortality and for the Welfare of Infancy on Breast-feeding with the exception of the note at the end and has no objection to the publication of the circular with an expression of this general approval.

The War.

THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue:—

Killed.

Capt. F. Hunton, R.A.M.C., attached Northumberland Hussars Yeomanry, received his medical education at Newcastle-on-Tyne, and qualified at Durham in 1891. Prior to joining the R.A.M.C. he was in practice at Sedgefield, Ferry Hill, in which district he held several appointments.

Died of Wounds.

Capt. G. S. Blandy, M.C., R.A.M.C., qualified at Edinburgh in 1902, and was medical officer at Napsbury Asylum previous to joining up. He formerly held appointments at the Norfolk and Norwich Hospital and at the Scarborough Hospital, and was for some time assistant medical officer at the Norfolk County Asylum at Thorpe. The award of the M.C. was announced in THE LANCET of June 10th, 1916, p. 1195.

Capt. J. Ewing, R.A.M.C., attached Royal Welsh Fusiliers, was educated at Leeds and qualified in 1903. Prior to joining up he was in practice at Leeds.

Died.

Major C. Ryley, R.A.M.C., was a student at St. Mary's Hospital, London, and qualified in 1901. After holding appointments at Paddington Green Children's Hospital and at St. Mary's Hospital, he joined the R.A.M.C. in 1904 and saw service in China and Bermuda. He went to the front in the middle of last year and contracted pericarditis, from which he died.

Capt. C. B. Burden, Australian A.M.C.

Wounded.

Capt. R. M. Alcorn, R.A.M.C., attached Northumb. Fus.
Capt. J. D. Marshall, R.A.M.C., attached Suffolk Regiment.
Capt. C. F. Searle, R.A.M.C., attached Northampton Regt.
Capt. O. C. S. Tandy, R.A.M.C., attached Seaforth High.
Lieut. J. Young, R.A.M.C., attached Gloucester Regiment.
Capt. P. E. Voss, Australian A.M.C.
Capt. I. D. Dickson, R.A.M.C.
Lieut. G. E. Spicer, R.A.M.C.
Capt. F. R. Armitage, R.A.M.C., attached R.F.A.
Capt. E. W. Adcock, R.A.M.C., attached E. Yorks Regiment.
Lieut. L. Kilroe, R.A.M.C.
Capt. J. M. Moyes, R.A.M.C.
Capt. H. G. Hobson, R.A.M.C., attached R.F.A.
Capt. E. S. Cuthbert, R.A.M.C., attached Middlesex Regt.
Capt. E. C. Gimson, D.S.O., R.A.M.C., attached E. Surrey R.

DEATHS AMONG THE SONS OF MEDICAL MEN.

The following sons of medical men must be added to our lists of those who have fallen during the war:—

Lieut. E. B. D. Brunton, Middlesex Regiment, only son of Dr. C. E. Brunton, of Walthamstow, London.
Second Lieut. J. Newton, H.A.C., younger son of the late Dr. W. T. Newton, of Lakenheath, Suffolk, and formerly of Goswell-road, London.
Second Lieut. J. C. Orr, Royal Berkshire Regiment, second son of Dr. W. R. Orr, of East Finchley, London.
Major J. H. Clapperton, Royal Field Artillery, third son of the late Dr. J. Clapperton, of Broughton, Hants.
Capt. T. S. King, East Surrey Regiment, only son of the late Dr. T. R. King.
Second Lieut. G. W. Clapham, Royal Field Artillery, second son of Mr. L. Clapham, M.R.C.S., of Thorney, Peterborough.

THE HONOURS LIST.

The following awards are made in connexion with the engagement between H.M.S. *Swift* and *Broke* and a flotilla of German destroyers on the night of April 20th–21st:—

Distinguished Service Cross.

Surg.-Prob. Christopher Thomas Helsham, R.N.V.R. (*Broke*)
Surg.-Prob. John Sinclair Westwater, R.N.V.R. (*Swift*).

Worked with great energy and ability in attending to the wounded.

The following award is also announced:—

Military Cross.

Capt. Stanley Sextus Barrymore Harrison, R.A.M.C., attached South Staffordshire Regiment.

For conspicuous gallantry and devotion to duty. He worked continuously for 10 hours under very heavy fire, and was responsible for saving many lives. He displayed great courage and determination throughout. He has on many previous occasions done fine work.

THE PARIS CONFERENCE ON THE WAR CRIPPLE.

The Conférence Interalliée pour l'Étude de la Rééducation Professionnelle et des Questions qui Interessent les Invalides de la Guerre was held in Paris, in the Avenue d'Antin side of the Grand Palais, from May 8th to 12th. That all sections of French society realise the national importance of the questions to be discussed was shown by the presence of labour leaders, socialists, heads of industrial concerns, agricultural syndicalists, lawyers, and deputies, as well as members of the medical and military professions and a fair sprinkling of disabled soldiers.

Delegates.—Official delegates were sent by each of the Allied Governments. The British delegates were: Lieutenant-Colonel Sir Arthur Griffith-Boscawen, M.P., Parliamentary secretary to the Ministry of Pensions; Major-General Russell (representing Sir Alfred Keogh); Sir Charles Nicholson, M.P., chairman to the Disablements Subcommittee of the London War Pensions Committee; Colonel E. A. Stanton, C.M.G., of the Statutory Committee; Colonel Stewart, representing the British Red Cross Society; Lord Charnwood, Comité Anglo-Belge; Lieutenant-Colonel Sir Berkeley Moynihan, C.B., M.S., F.R.C.S., R.A.M.C.; Major Robert Mitchell, Adviser to the Minister of Pensions on Training; Fleet-Surgeon Percy H. Boyden, R.N.; and Lieutenant-Colonel Finlay, C.A.M.C., and Captain C. McClure, C.A.M.C., representing Canada. The English members attending the Conference were Lieutenant-Colonel Sir Thomas Oliver, Colonel J. Wallace, Colonel J. Cowen, Colonel J. Reed, and Mr. Samuels.

Organisation.—The Conference was organised by a Franco-Belgian committee under the presidency of Baron de Brocqueville, the Belgian Minister of War; M. Léon Bourgeois, the French Minister of Labour; M. Justin Godart, head of the French Army Medical Service; and M. Roden, Under Secretary of Labour; and was formally opened on Tuesday, May 8th, in the presence of the President of the French Republic. The members were divided into six sections, classified by the questions to be discussed and meeting at the same time in different rooms. While this plan facilitated the covering of much ground in a short time the drawback was only seen at the general meeting of all the sections at the end of the Conference, when it was found that the questions discussed were so interrelated that not only had it been possible for some of the sections to arrive at different conclusions as to the same subject, but that three or four had made the same recommendation in different terms. Since many of the 80 decisions voted will have to be re-edited to avoid repetition, it was finally decided not to publish any of them for the present. Some of the most important points dealt with may, however, be noted.

Work of Sections.—The first section, presided over by Senator Mélis, Inspector-General of the Belgian Medical Service, discussed physical re-education from the point of view of—(*a*) physiotherapy and medical gymnastics; (*b*) artifical limb appliances; and (*c*) work as an agent of physical restoration.

(*a*) The Belgian school of treatment, voiced by Dr. Marneffe, director of the Belgian Military Hospital of Bonsecours at Rouen, is in favour of Swedish methods of gymnastics and massage, and inclined to the use of mecano-therapic apparatus of the Zander type. This view was not shared by the majority of his colleagues, and it was decided to develop on lines not necessarily Swedish. The omission of any paper on X ray and hot-air treatment was commented upon by M. Laborde and Dr. Zimmern. "La gymnastique médicale" applied to men suffering from lung wounds was advocated by Dr. Philippe Tissié, of Pau, and an interesting paper by Dr. Schaer, of the Hôpital du Grand Palais, demonstrated the cure of muscular contraction in less than 15 days by a course of "mobilisation rééducative." Dr. Larat and Dr. Billiard insisted on the importance of electro-diagnosis in nerve wounds, particularly in view of the patients' future, as they must be enabled to work while undergoing treatment.

(*b*) The question of prothesis is a complex one in France, but as the difficulty is more or less a domestic one it does not greatly affect the other Allies, and the recent establishment of a Commission by the Service de Santé will doubtless solve the problem. Professor Putti, of Bologna, upheld the employment of the so-called "American" artificial limb, but many of the French surgeons prefer their own types. Some of these are very much cheaper than the English ones, but it is not yet possible to judge of their lasting qualities.

(*c*) Sir Berkeley Moynihan briefly described the system for orthopædic treatment of the wounded in the British Isles. He pointed out that many of the conditions now

needing treatment could be prevented by timely attention to sound principles. Joints in which ankylosis was inevitable could be fixed at better angles. Joints whose nerve-supply was severed might be kept supple, and tendons might be spared the overstretching of their fibres, from which recovery was so difficult. The various forms of treatment at orthopædic centres and in "curative workshops" attached to them necessitate constant control by the surgeon. Instruments of the Zander type were chiefly useful when looked upon either as mechanisms to be worked by the injured member rather than as a means whereby joints were quietly rocked by the agency of a sound limb, or as preparatory to or auxiliary to those purposeful exercises in which the patient had something to see and show as a result of his labours. The importance of the fact that a man's mind as well as his muscles should be engaged in the task of restoring function was pointed out. In the curative workshops a patient quickly regained self-reliance when he found himself once more a useful working member of society.

The chances open to the discharged disabled soldier in the labour market were discussed, and the relations of the Pensions Ministry to these problems briefly reviewed. The paper ended with a tribute to the constant help given to orthopædic work by the British Red Cross Society and by their representative, King Manuel of Portugal.

Among the suggestions made in Section I. were several concerning the class of agricultural labourers, which is far larger in France than in England. It was felt that any organisation to further functional restoration by means of agricultural work should pay great attention to special conditions of each region, and not form any stereotyped plan. It was also pointed out that (1) any work undertaken as auxiliary to physio-therapic treatment should be chosen by the medical director and remain under his close surveillance; (2) such work should be made obligatory in all physio-therapic institutions; (3) schools for functional restoration should be placed under the single control of the Service de Santé; (4) schools for professional re-education should be directed by a committee representing (*a*) medical men, (*b*) employers, (*c*) skilled workmen, (*d*) labour unions.

A paper was read by Captain C. McClure describing the treatment given at the Canadian Hospital at Ramsgate, and another on Les Appareils de Prothèse was sent in by MM. Rieffel and Gourdan.

Section II.—In this section, presided over by Dr. Bourillon, the director of the well-known Institut National Professionnel des Invalides de la Guerre at St. Maurice, there was much discussion as to whether the doctor or the instructor should have more authority over the disabled. The opinion was expressed that doctors should direct the industrial work and teachers should execute it. A Portuguese delegate opposed this idea on the ground that, generally speaking, doctors were not sufficiently trained to carry out the education of the maimed, but should limit themselves to advising what kind of work they could do. Mistakes had been made, and men had been obliged to change their occupation. In view of the fact that overcrowding in one trade in certain localities may occur, as at Bordeaux, where the majority of the disabled have chosen commercial occupation, an inquiry was advised as to the losses sustained through the war in each trade, so that an equilibrium may be maintained in filling the gaps. Men wishing to take up a non-manual occupation should be examined as to capacity. It was also pointed out that there was a wide field for training men in the mechanism and working of agricultural motor tractors, which can be used all the year round in the French and Belgian villages for different purposes. The establishment of a permanent inter-Allied committee to keep in touch with and disseminate news of the work done for the disabled in all the Allied countries was voted for in this as well as in several other sections.

Section III.—This section, under Senator Bérenger and Sir Thomas Barclay, discussed the placing of the disabled in civil life. Here, again, the different conditions obtaining in England and France gave this problem rather a personal flavour. The creation last year of l'Office National des Mutilés et Reformés de la Guerre, under the joint direction of the Ministries of Labour, War, and Interior, does not seem to have smoothed out all difficulties, since one of the changes most ardently demanded in this section was unification of the employment bureaux for agriculture, industry, and commerce, the same bureau to serve both for disabled and valid men. Even though France, having had a greater number of men first in the field, and consequently a greater number of casualties, has felt the pressure of this problem before England, the opinion of the section seemed to be that it had been more carefully thought out in England. Lord Charnwood explained the English expedient of the creation of a Ministry of Pensions to solve this difficulty instead of leaving it to be shunted about between three Ministries as in France. Another point commended by the French members of this section was the creation by the Ministry of Labour at the request of the Ministry of Pensions of joint committees of masters and men to settle such questions as rates of pay for the disabled. Lord Charnwood also explained that local organisations under the Ministry of Pensions have been constituted to deal with all the various requirements now occupying the attention of this section. One of the duties of these local committees in the neighbourhood of a hospital is to get in touch with the men before they are discharged and do everything possible in the way of interest and influence to help them to make the best of their lives The French members, who are keenly alive to the difficulty of dealing with men whose mental outlook has been affected either by their sufferings or by the enervating conditions of hospital life, were particularly appreciative on this point.

Section IV.—This section was concerned with the economic and social interests of the disabled. Among the papers read and discussed was one by the President of the Section, General Malleterre, who advocated the reorganisation of the Hôtel des Invalides for the reception of a number of war pensioners incapable of earning their living. The report prepared by Major Robert Mitchell pointed out the results of the system recently adopted in England—that the ultimate decision as to his future was left to the man himself; that instruction was given according to the needs of the different localities; that institutional workshops had been created specially for men incapable of competing with valid men, &c. The section voted for the creation in the other Allied countries of such special workshops as those existing in England.

Section V.—This section met to discuss the difficulties of the blind, the deaf, and the nerve cases. Under the presidency of M. Brieux, of the Académie Française, several interesting votes were taken after discussing papers by Dr. F. Chavanne de Lyon, Médecin-Major Jean Camus, Médecin-Major Roussy, and others. Among the measures voted for were those concerning the pre-re-education, the re-education, and the return home of the blind soldier. As far as possible it is proposed to carry out the treatment of the blind on the lines first laid down by Saint Louis when he founded the Hospice des Quinze-Vingts and allowed his blind beggars to live there with their families. Husbands and wives are not to be separated, but lodgings are to be found for them near their work.

Section VI.—The work of this section was concerned with the documentation and propaganda of matters relating to the disabled. Here, too, a vote was given for the formation of a permanent Central Inter-Ally Committee to hold all documents and information as to steps taken in different countries at the disposal of inquirers. The greatest interest was shown by the President of the section, M. Honnerat, and the other members in the accounts of English methods of dealing with the return of the disabled soldier to civil life, and especially the liberal financial provisions for men undergoing training and treatment, given by Sir Arthur Griffith-Boscawen and Sir Charles Nicholson, who had concisely detailed the measures taken by the Government in the questions of pensions, re-education, &c. The published report made by Sir Alfred Keogh, and included in the brochure of the collected reports which had formed the basis of the discussions, was studied by the members of all sections. The following resolutions were passed at the last meeting of the section:—

1. That since the question of the disabled as to pensions, professional re-education, placing, and social protection is common to all the countries of the Entente, and that it is to the interest of each of these countries to seek a solution that will be the logical result of the experience gained; that since this result can only be obtained by the organisation of an inter-allied bureau of documentation in the matter; that while waiting for the creation of such bureau through the coöperation of the Governments interested, the Direction of the General Statistic Department of France be at once charged to gather such documents with a view to publishing and communicating to Allied countries such details on each question as may be asked.

2. (*A*) That an active and coördinated propaganda should be organised in each of the Allied countries by tracts, addresses, lantern

lectures, meetings, &c.: (1) To make known in all parts of the country the resolutions adopted by the Inter-Allied Conference; (2) to make the disabled understand the reasons that determined these resolutions, as well as the advantages to be gained for them and for the country; and (3) to combat opposition tendencies and open or secret opposition propaganda. (*B*) That in order to facilitate professional re-education (1) the authorities undertake the expense of this re-education as well as the maintenance of the disabled man and of his family during the course; (2) that a special propaganda should be carried out among the doctors and nurses of hospitals as well as in the institutions for re-education with a view to accentuate their effort to persuade the disabled to fit himself for work according to the resolutions of the committee with due attention to the normal outlets in each region. (*C*) That a permanent inter-Allied committee should be instituted to maintain the bonds that have been created by the Conference between the institutions and the people who have shared in the work and prepared the ulterior meetings.

Exhibition.—Not the least interesting part of the Conference was the exhibition arranged in the galleries of the Grand Palais showing (1) charts, statistics and photographs of the different institutions for the disabled; (2) artificial limbs used in re-education, arms and hands for work purposes, instruments and tools adapted for use by the disabled; (3) inventions, games, modifications of tools and ingenious methods of relieving the helplessness caused by the loss of limbs. All the exhibits belonging to the French Army Medical Service or the institutions under its control are to be removed to the permanent war medical and surgical museum now installed in the Val-de-Grâce, and the manufacturers of the different prothesis appliances are to be asked to add where possible specimens of their work.

The proceedings of the Conference were varied by the visits of inspection paid by the members to the École d'Agriculture at Grignon, to the École Nationale de Ré-éducation at St. Maurice, and to the Belgian School for the disabled at Port Villez.

From the English point of view the great value of the Conference was confirmatory. Where methods sometimes differed slightly it was seen that each country was moving largely along the same lines only varied by local conditions. Many phases of the English problem differ from the French owing to the fact that the agricultural question is so much more important in France, where 40 per cent. of the men mobilised and 37·5 per cent. of the disabled belonged to the agricultural class.

While the French system of keeping the disabled under military authority until a complete cure is effected does away with the difficulty of after-treatment, in the matter of professional training they have to cope with the same difficulties.

Many of the discussions that took place were more or less of a domestic character, but the Portuguese, Serbian, Russian, Italian, and British members of the Congress listened to the Belgian and French problems with an interest which was, as M. Léon Bourgeois expressed it in his opening speech, a sign of "solidarité morale" among the Allies.

THE UNITED STATES AND MEDICAL ORGANISATION FOR THE WAR.

Hospital Staffs.—The Hospital Committee of the Council of National Defence has recommended general hospitals throughout the country, having a capacity of 100 beds or over, to reorganise their staffs in order to allow every available man to join the Medical Reserve Corps of the Army and Navy. The men selected to remain with their home hospitals will wear a badge to indicate that they are performing indispensable home service. The suggestion has been made to draw up a list of all available hospital accommodation at convenient points along the Atlantic and Pacific coasts and of special facilities for the treatment of neurological, orthopædic, and shell-shock cases.

Hospital Units for France.—Six base hospital units have been organised and notified to hold themselves in readiness to be sent to France within the next few weeks. They will be in charge of Dr. G. E. Brewer, Dr. George W. Crile, Dr. Harvey Cushing, Dr. Richard H. Hart, Dr. Frederick Besley, and Dr. Frederick T. Murphy. American surgeons for service with the Army in France will go as members of the medical corps of the United States Army. Each hospital unit consists of 23 medical men, 2 dentists, 65 nurses, and 150 enlisted men of the medical department. In addition to these units, which are each capable of attending to 500 men, the statement is again made that 1000 American surgeons are ready to put themselves at the disposal of the Allies in Europe.

The Supply of Medical Men.—As in this country, the question of emergency alterations in the medical curriculum is being considered. At a recent meeting of the General Medical Board of the Council of National Defence the question of keeping the medical schools of the country in continuous operation was discussed, and the State Boards of Medical Registration were asked to consider the recognition of the "continuous teaching plan" as an equivalent of the usual four-year course, as well as the recognition of various forms of substitute work.

THE EXCHANGE OF INVALID PRISONERS OF WAR.

A certain number of prisoners of war, both British and German, have been repatriated from their internment in Switzerland, but a good deal of disappointment is felt in this country that the number has been so small. Mr. Hume-Williams, whose question in the House of Commons gave expression to this feeling, evoked the reply from Mr. J. F. Hope, the representative of the War Prisoners Department, that the qualification for exchange from internment in Switzerland is the same standard of physical disability as that demanded in the case of men repatriated direct from prisoners' camps. This standard, as we saw in THE LANCET of April 29th and June 10th, 1916, is a high one, although it is not so high for men in the ranks as for officers. The loss of a limb in an officer, whether commissioned or non-commissioned, renders the prisoner eligible only for internment in Switzerland, whereas privates similarly mutilated are repatriated. Mr. Hope thought it unlikely that many of our interned men will qualify for repatriation under the present rules. As this would involve a considerable increase in disability, we can hardly wish them to do so.

THE TREATMENT OF MEN DISCHARGED FROM THE ARMY ON ACCOUNT OF NEURASTHENIA.

Provision is being made for the institutional treatment of men discharged from the Army on account of neurasthenia, shell shock, and allied nervous conditions, at a branch hospital attached to the Hospital for Epilepsy and Paralysis, Maida Vale. This hospital was founded 50 years ago for the treatment of a class of patient whose needs up to the present time have not been recognised by the State, and has accepted the responsibility for the treatment of functional nervous disorders arising in civil and industrial life. Since 1896 an attempt has been made with some success to act as third party between employer and employee under the Workmen's Compensation Acts. Light employment is the great desideratum for these cases, but in industrial life there is great difficulty in finding the suitable milieu to enable them to become fit or hardened before returning to employment. In the Army this need has been met by the institution of Command Depôts. A man broken by strain is more likely to break down when subjected to similar strain than when put to a changed mode of life, and experience has shown that cases of nervous breakdown previously engaged in professional or clerical work do well when sent to sea or on taking up farm work. The exigencies of the Service do not permit of such consideration of the individual being given prior to discharge, and hence invaliding is a necessary stage in the recovery of the neurasthenic. This has been recognised in the recent Military Service Revision Act, which excludes from its operation men suffering from functional nervous disorders. These pensioners nevertheless require an environment suitable for the restoration of their mental powers, which demands suitable oversight and stimulating interests. A careful study has to be made of the previous life, interests, and ability of the patient, as well as of the stock from which he came. At "Highfield," Golder's Green, the new branch of the Maida Vale Hospital, only selected cases of patients suffering from functional nervous disorders are to be admitted. The institution occupies the buildings of a former well-known girls' school, and contains accommodation for 150 persons, including 35 single-bed wards. A gymnasium is provided, surrounded by large well-wooded grounds. The facilities offered include: (1) Isolation beds with provision for local and general massage, and the application of modern electro-therapeutic treatment; (2) a gymnasium equipped for physical drill and Swedish exercises; (3) a range of workshops; (4) organised games with instructors;

(5) personal contact with a trained staff; (6) an employment bureau and after-care in conjunction with the Local Pension Committee. Generous terms have been granted by the Ministry of Pensions, so that all who enter the hospital will receive a pension, while the wives and children of married men draw separation allowance.

THE Naval Hospital, Truro, has received the sum of £50, being a portion of $500,000 recently raised by means of a bazaar at Chicago.

THE President of the French Republic has appointed Surgeon J. D. Milligan, R.N., to be a Chevalier of the Legion of Honour.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

Surgeon-General William H. Norman, C.B., has been appointed to succeed Surgeon-General Sir Arthur W. May, K.C.B., as Director-General of the Medical Department of the Navy from June 1st, 1917, and has been granted the relative rank of Vice-Admiral.

Surgeons to be Staff Surgeons: H. F. Briggs, M. P. Fitzgerald, A. G. Malcolm, H. C. Devas.

To be temporary Surgeons: M. McKerrow, R. N. B. McCord, S. L. Higgs, and A. J. Muirhead.

The following appointments have been notified:—Fleet-Surgeons: R. M. Richards to *Powerful*; R. F. Clark to *Vivid*; and C. J. H. Cock to *Suffolk*. Staff Surgeons: D. H. C. Given and R. M. Riggall to *Donegal* and *Hearty* respectively. Surgeon: P. B. Wallis to Portland Hospital. Temporary Surgeons: A. P. Barrett, F. G. Lloyd, and K. H. McMillan to *Victory*; R. N. B. McCord to Haslar Hospital; M. McKerrow to Chatham Hospital.

ARMY MEDICAL SERVICE.

Lieut.-Col. C. H. Hawkins to be temporary Colonel whilst holding the appointment of Assistant Director of Medical Services.

Lieut.-Col. A. L. A. Webb, C.M.G., to be an Assistant Director-General (temporary).

ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. H. J. Hargrave, Suffolk Regiment (T.F.), to be temporary Lieutenant-Colonel.

To be acting Lieutenant-Colonels whilst in command of a Field Ambulance: Majors: E. E. Powell, H. W. Russell, and A. W. Gibson. Captains: T. J. Mitchell, J. W. L. Scott, and G. P. Taylor.

To be acting Lieutenant-Colonels whilst in command of a General Hospital: Majors J. G. Foster, J. F. Whelan, and Capt. C. H. H. Milner (T.F.).

The undermentioned are granted temporary rank: As Lieutenant-Colonel: S. H. Taylor, A. R. Parsons. As Major: W. A. Winter, R. C. B. Maunsell, K. E. L. G. Gunn. As Captain: W. Boxwell, C. E. Boyce, F. H. Mc C. Crawley, E. J. M. Watson.

Temporary Majors to be temporary Lieutenant-Colonels whilst employed at hospitals as stated: H. W. Bruce, Southwark Military Hospital; J. H. Brooks, Mile End Hospital; W. D. Buncombe, City of London War Hospital; W. Scatterty, Keighley War Hospital; F. S. Toogood, Lewisham Military Hospital.

Temp. Hon. Capt. M. Gamble to be temporary honorary Lieutenant-Colonel whilst serving with Withington War Hospital.

Major (Brevet Lieut.-Col.) H. J. Crossley to be acting Lieutenant-Colonel whilst in command of a Stationary Hospital.

Captains, R.A.M.C. (T.F.), to be temporary Majors: L. G. Parsons, G. P. Mills.

Capt. B. Biggar is seconded for service with Egyptian Army.

To be temporary Majors: W. A. Brend, F. L. Collie, J. Kerr, W. D. Knocker, Temp. Capt. H. F. Woolfenden, and W. E. N. Dunn (whilst employed at the Horton (County of London) War Hospital).

To be temporary Captains: Temp. Lieut. P. C. E. d'E. Wheeler and Temp. Lieut. G. de B. Turtle.

To be temporary Honorary Lieutenant: C. E. Fearn.

To be Lieutenants: V. T. Borthwick Yule and A. G. Lumsden (from Aberdeen University Contingent, O.T.C.), R. Lloyd-Jones and W. Christopher.

Officers relinquishing their commissions: Capt. T. E. Roberts (on account of ill-health caused by wounds; granted the honorary rank of Captain) and Temp. Lieut. D. E. H. Cleveland.

The undermentioned officers of the Canadian Army Medical Corps are appointed as follows:—Col. H. A. Bruce is seconded for service with the British Medical Services as a Consultant Surgeon.

To be temporary Colonels: Temp. Col. G. E. Beauchamp, Temp. Lt.-Col. H. A. Onisholm, D.S.O., and Temp. Lt.-Col. H. A. Bruce.

To be temporary Lieutenant-Colonels: Temp. Maj. W. T. Connell, Temp. Maj. J. R. Spires, Temp. Lt.-Col. K. D. Panton, Temp. Maj. C. H. Reason (while specially employed).

To be temporary Majors: Temp. Capt. J. N. Gunn, Temp. Maj. G. E. Gillies, and Capt. T. H. McKillip, D.S.O.

Temporary Captains to be temporary Majors: G. H. Kidd, S. M. Polson, W. H. Ballantyne, J. P. Quigley, G. A. Platt, W. F. Nicholson, and N. J. Barton.

G. W. Badgerow to be temporary Honorary Major.

To be temporary Captains: C. A. Yates, J. W. Begg, Temp. Capt. F. H. H. Mewburn, F. X. O'Connor, G. E. Millette, C. G. Main, A. D. Campbell, C. R. Wallace, Temp. Lieut. R. H. Bonnycastle, Temp. Lieut. E. V. Frederick, and Temp. Lieut. G. S. Gordon.

To be temporary Lieutenants: C. A. Brisco, B. E. Scott, C. M. Keiller, R. B. Martin, M. E. Gorman, H. W. Whytock, D. A. Murray, H. McKinnon, W. J. Bell, A. R. Mann, and L. D. Orr.

Temp. Maj. J. N. Roy resigns his temporary commission.

The undermentioned officers of the Canadian Army Dental Corps are appointed as follows: Temporary Captains to be temporary Majors: J. E. Holmes, W. J. Bentley, W. R. Greene, A. E. Mullin, G. N. Briggs, L. N. Trudeau, G. H. A. Stevenson, J. F. Blair, G. S. Cameron, C. E. Brown, and O. A. Elliott.

To be temporary Captain: L. R. Dufresne.

To be temporary Lieutenants: A. C. Steele, J. W. McDonald, and A. G. Lough.

SPECIAL RESERVE OF OFFICERS.

Lieutenants to be Captains: G. H. Barry, C. P. L. Carrier, F. G. L. Dawson, R. R. Scott, M. C. Cooper, D. H. Anthony, J. J. Murphy, and A. G. Harsant.

To be Lieutenants: D. C. Beaumont, C. V. Pink, H. W. Leetham, W. G. Woolrich, J. E. Carpenter, E. B. Andreae, A. G. E. Wilcock, J. B. S. Lewis, and T. Hawke McLeod (from the University of London Contingent O.T.C.), C. C. Chesterman (from Bristol University Contingent O.T.C.), and J. C. Collins.

TERRITORIAL FORCE.

Captain J. D. Allen, from Territorial Force Reserve, to be Captain.

Major D. L. Fisher to be acting Lieutenant-Colonel whilst commanding a Field Ambulance.

Major D. W. Patterson to be acting Lieutenant-Colonel whilst holding the appointment of Administrator.

Captain W. T. Harkness to be acting Major whilst holding the appointment of Registrar.

The undermentioned Lieutenants to be Captains: A. C. Bescoby and M. Wilson.

To be Lieutenant: J. H. Churchill (from Territorial Force Reserve).

VOLUNTEER FORCE.

H. Chadwick, 11th Battalion, Lancashire Volunteer Regiment, to be temporary Captain and Medical Officer.

NEW MEDICAL LEGISLATION IN SOUTH AFRICA.

A South Africa Correspondent writes as follows: The Union Government has introduced a Medical, Dentistry, and Pharmacy Laws Consolidation Bill into the South African Parliament, and at the time of writing it has passed a second reading in the Senate and been referred to a Select Committee of that House. The Bill was introduced into the Senate by the Minister of the Interior (Sir Thomas Watt), who moved its second reading on March 19th. The Bill is styled a Bill for the purpose of consolidating and amending the laws in force in the Union relating to medical practitioners, dentists, chemists and druggists, midwives, and trained nurses; the keeping and sale of poisons; the importation, sale, and use of habit-forming drugs; and other matters relating thereto. It was introduced first in the Senate, and not, as is usual, in the House of Assembly. Sir Thomas Watt said that the Bill was intended to protect the public and the profession against improperly qualified practitioners, and also to apply the principle of reciprocity as between the Union of South Africa and other countries granting medical degrees and, of course, recognising the medical diplomas granted by British universities. There was nothing in the Bill to prevent storekeepers in South Africa from selling sheep dips or even patent medicines, provided that there was no chemist within five miles. Any storekeeper could, of course, sell patent medicines that did not contain poison. The farmers' coöperative societies would be allowed to sell certain poisons to their members. Dealing with novel features of the Bill, Sir Thomas Watt said that a new principle had been introduced, to the effect that the seller of poisons must add a leaflet showing the antidotes to such poisons should they be taken in mistake. Restrictions were placed by the Bill on the sale of drugs producing evil habits. A difficulty had arisen in dealing with "dagga" smoking amongst the natives, as the herb grew wild in many parts of the Union. One subject dealt with in the Bill was the grievance that some medical practitioners who could practise in the Orange Free State and the Transvaal were debarred from doing so in the Cape and Natal, owing to the absence of reciprocity respecting foreign diplomas and degrees. The South African Union was making arrangements for a three-year medical course, and in due time, the Minister said, they would have a full medical course in South Africa. At present the course had to be completed elsewhere. The registration fee for a medical practitioner, £25, was rather high, but the wish was to make the Medical Council self-supporting. A pharmacist would pay £12 10s. Sir John Fraser thought that the Government should schedule in the Bill foreign diplomas which would not be accepted. Sir Meiring Beck, replying to the suggestion of scheduling, said that medical schools were changing every day. They could not, therefore, adopt a cast-iron system, but must adapt themselves to change of circumstances. He pointed out that the Medical Council of Great Britain, which had worked smoothly for many years, was constituted exactly as that proposed in the Bill.

Dr. E. Graham Little has been elected by his fellow graduates in medicine and surgery of the University of London to fill his fourth term of office (1917–1921) as their representative on the Senate of the University.

THE TREATMENT OF AMŒBIC DYSENTERY.

To the Editor of THE LANCET.

SIR,—In your issue of July 29th, 1916, you published a note by me on Treatment of Carriers of Amœbic Dysentery, in which I gave reason for supposing that the double iodide of emetine and bismuth would be useful in such cases, and recorded some preliminary results obtained by those who were giving the suggestion a clinical trial. Since then several reports have been published on the action of this compound, and these have, on the whole, so strengthened the preliminary impression formed of its probable value that its use, at any rate in the immediate future, seems likely to be extensive.

My own connexion with the matter has been slight, but I appear to be primarily responsible for a historical injustice, the rectification of which is my object in writing to you now. My note of July, 1916, referred to a paper published in 1915 by Du Mez, in which the double iodides of emetine with bismuth and with mercury were described, and their use suggested to ensure the passage of emetine through the stomach and its gradual liberation in the intestine. I was at that time quite unaware of the fact, which Du Mez also had evidently overlooked, that a compound of this kind had been prepared as long ago as 1891 by the late Major Warden, I.M.S., and an account of its use in the treatment of dysentery published in the same year by Surgeon-Captain Tull Walsh, I.M.S. (now Lieutenant-Colonel, retired) in the *Indian Medical Gazette* (vol. xxvi., p. 269, 1891). The "emetine" of those days was an impure mixture of the alkaloids of ipecacuanha, and the differentiation of amœbic from bacillary dysentery was then still a matter of dispute. But by careful clinical observation of cases of "acute dysentery" Captain Walsh established two points: firstly, that the curative effect of ipecacuanha in dysentery was due to its alkaloids (the "emetine" of that date), the drug being inert when freed from these completely; and, secondly, that the "emetine" could be effectively administered for this purpose by the mouth in the form of its double iodide with mercury. In the one case he clearly anticipated the discoveries made 20 years later by Vedder and by Rogers, though the intervening development of chemical and protozoological knowledge gave a greater precision to their observations; in the other case he even more definitely anticipated, by a quarter of a century, what we have been regarding as a recent development of the emetine treatment.

I need hardly point out that this acknowledgment affects only my own small and secondary share in the introduction of emetine bismuthous iodide into practice, and in no degree affects the credit due to those whose patience and skill, whether in ward or laboratory, have demonstrated the value of this compound in conditions which the hypodermic method often fails to cure. Their work has, of course, been largely concerned with infections which the methods of 1891 could not have detected at all.

I should add that Colonel Walsh has had no part in this attempt of mine to repair the injustice of failing to mention his observation of so many years ago. I wrote to him when I discovered it; and, in a letter of most kindly encouragement which he sends me in reply, he expresses his own attitude as follows: "So long as good work is done I do not care who does it."

I am, Sir, yours faithfully,

May 7th, 1916. H. H. DALE.

BLACKENING OF TETANUS CULTURES.

To the Editor of THE LANCET.

SIR,—In your issue of May 5th Mr. R. S. Adamson and Mr. D. W. Cutler in their paper, entitled "Note on a Bacillus resembling *B. tetani*," quote my statement that *B. tetani* produces blackening in meat medium. I should be glad if you would allow me the courtesy of your columns to correct this statement which is an error on my part. The tetanus culture which I described was later found to be contaminated with a proteolytic organism. At the time of writing, although I was alive to the difficulty of obtaining anaerobes in pure culture from wound material, I was not prepared to find that the same difficulty would arise in dealing with laboratory tetanus cultures of long standing. The reactions of this impure culture agreed with the account of *B. tetani* given by v. Hibler and with that of v. Lingelsheim in Kolle and Wassermann's edition of 1912. I am engaged in investigating various tetanus cultures, with results which will be published in due course. I am not at present quite prepared to state what the cultural reactions of a pure tetanus culture are, but I have found that tetanus cultures, when freed from this foreign proteolytic organism, do not cause blackening of the meat medium.

I am, Sir, yours faithfully,

MURIEL ROBERTSON.

Lister Institute of Preventive Medicine, Chelsea, S.W., May 9th, 1917.

WHOLE-TIME APPOINTMENTS AND THE POSITION OF TEMPORARY MEDICAL OFFICERS IN THE NAVY OR ARMY.

To the Editor of THE LANCET.

SIR,—Since August, 1914, a number of vacancies caused by death or resignation has occurred in the Public Health Service. At many places temporary appointments only have been made, and the posts are to be advertised and duly filled up permanently when this great war is at an end and competition will be unrestricted.

However, some whole-time places have been permanently filled by men "on the spot." Is this fair or just to those who have joined up to serve our King and country and so have no chance of competing for these posts?

There is no credit attached to men who obtain places for which probably they would have had no selection if pre-war conditions existed, and they had had to range themselves against men better qualified for important work than these interlopers are.

I hold strongly that the Local Government Board ought not to penalise patriotism by approving any appointments in the public health or school medical or Poor-law medical services except temporarily and only for the duration of the war. I have reason to know that this neglect of their interests is giving rise in certain instances to considerable dissatisfaction amongst medical men serving abroad.

I am, Sir, yours faithfully,

May 7th, 1917. "FAIR PLAY."

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At a meeting of Comitia of the Royal College of Physicians of London on April 26th and of the Council of the Royal College of Surgeons of England on May 10th, diplomas of L.R.C.P. and M.R.C.S. were respectively conferred upon 103 candidates—93 men and 10 women—who have passed the Final Examination of the Conjoint Examining Board and have complied with the by-laws of each College. The following are the names and medical schools of the successful candidates:—

Gustave Adler, London; Ewart Gordon Anderson, New Zealand and London; Eric Burn Andrese, Otago and London; Philip Ardern Ashcroft, Manchester; Eric Victor Beale, Cambridge and London; Douglas Charles Beaumont, Cambridge and London; Wilfrid Thomas Beswick, Cambridge and St. Thomas's; Alethea Josephine Bolton, Birmingham; Alfred Octavius Bolton, St. Bartholomew's; Alfred Henry Boon, Chicago; Marian Noel Bostock, St. George's and Royal Free; Ernest William Bowell, Guy's; James Bassett Brash, Cambridge and St. Bartholomew's; Israel Braun, St. Bartholomew's; Edward Davenport Broster, Cambridge and University College; Donald Cameron, St. Bartholomew's; Oliver St. Leger Campion, Guy's; James Edwin Carpenter, London; Kathleen Lydia Cass, Manchester; Harold Chadwick, Cambridge, St. Bartholomew's, and Manchester; Clement Clapton Chesterman, Bristol: Henry Joseph Constantine Churchill, St. Bartholomew's; Stella Churchill, Royal Free; Antonio Mario Clément, St. Thomas's; Geoffrey Francis Cobb, St. Bartholomew's; Joseph Clinton Collins, London; Rupert Shelton Corbett, Cambridge and St. Bartholomew's; Ralph Coyte, St. Bartholomew's; William Cramer, Edinburgh and University College; Thomas Morley Cunnington, University College; Peter Gerald Stevenson Davis, St. Thomas's; Howard Lexster Douglas, London; Frances Jane Du Pré, Manchester and Charing Cross; John Rosslyn Earp, Cambridge and University College; Mahmoud Erfan, Cairo and St. Bartholomew's;

James Fairbrother, Cambridge and London; Robert French, Cambridge and St. Bartholomew's; Philip Edward Francis Frossard, London; Hugh Gainsborough, Cambridge and St. George's; Lawrence Gill, Guy's; Henry Gluckman, London; Edward Francis Strathearn Gordon, Cambridge and St. Bartholomew's; Mendel Gourevitch, Paris and London; Grace Mary Gulston Griffith, University College, Cardiff, and Leeds; Leslie Briggs Hartley, Cambridge and St. Thomas's; Frederick John Harvey, Birmingham; Lily Fanny Harwood, Royal Free; Sydney Limbrey Higgs, Cambridge and St. Bartholomew's; Harold Whewell Hogarth Holmes, Cambridge and St. Thomas's; Cawas Homi, Bombay and Middlesex; Joseph Christopher Campbell Howe and George Raymond Hubbard, Guy's; Oscar Hyam Hyman, St. Thomas's; Karam Chand Jaiska, Leeds and Bristol; Loiza Elwell Johnston, American Medical Missionary College; David Bruce Stewart Jones, Charing Cross; David Joseph Heritage Jones, St. Mary's; John Isaie Keen, Charing Cross; James Douglas Kenyon, Manchester; Hugh William Leatham, Cambridge and St. Thomas's; Harold Warburton Lewis, Middlesex; John Biddulph Strafford Lewis, Cambridge and St. George's; Isaac Jacob Lipkin, Liverpool; Evan Edwards Llewellyn, Cambridge and St. Bartholomew's; Leslie Grantham Lunnon, Middlesex; Thomas Hawks McLeod, St. George's; Arthur Neil McMillan, Middlesex; William Marriott, St. Thomas's; John Aston Martin, Cambridge and Guy's; Harold George Victor Mence, Birmingham; Frederick Maurice Mosely, Cambridge and London; Christopher Kilvinton Mowll, London; William Watson Newton, Birmingham; Arthur Leslie Packham, Middlesex; Alexander Edward Patrick Parker, Westminster; Andrew Harman Pearce, Cambridge and St. Thomas's; Cyril Valentine Pink, St. Thomas's; William Irving Fitzgerald Powell, London; Henry Norman Pritchett, Guy's; Walter Murad Abdul Rahman, University College; Ronald Eric Rampling, St. Thomas's; David William Ryder Richardson, Cambridge and London; Ralph Leslie Robinson and Arthur Rose-Innes, University College; John Rowland, St. Thomas's; John Douglas Rutherford, Cambridge and St. Bartholomew's; James Jules Avit Scott, Birmingham; Norman Fairbanks Smith, Oxford and St. Bartholomew's; Eric Dickens Spackman, Cambridge and St. Bartholomew's; Meredith Blake Robson Swan, Cambridge and King's College; Ellen Sylk, Royal Free; Ronald Henry Tasker, Bristol; John Percy Reginald Tennekoon, Ceylon Medical College and London; Lewis Henry Douglas Thornton, Cambridge and Middlesex; Frederick FitzGerald Tisdall, Toronto; William James Walters, Cambridge and Guy's; Francis Eaton Gordon Watson, St. Bartholomew's; Winifred Hannah Wells, Sheffield; William Harold White, St. Thomas's; John Prichard Williams, University College Cardiff and Westminster; James Harry Wiseman, Sheffield and London; Leonard Heatley Woods, St. Bartholomew's; and William Grant Woolrich, Cambridge and St. Thomas's.

The Licence in Dental Surgery was also conferred upon Mr. Percy King, Guy's Hospital, who has passed the requisite examinations and complied with the by-laws.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.

—As the result of the Final Examination, held from April 10th to 27th, the following candidates were approved in the undermentioned subjects, but have not yet completed the examination:—

Medicine.—A. L. Abel, University College; K. A. Anklesaria, Bombay and London; H. C. Apperly, Middlesex; E. B. Ash, Birmingham; Ruth Balfour, Royal Free; N. A. H. Barlow, Guy's; G. Bourne, St. Bartholomew's; F. Cameron, Charing Cross; H. Carpenter, University College; O. C. Carter, London; Annie Clark, Sheffield; Ruth Eden Conway, Manchester; A. J. Copeland, Glasgow and St. Bartholomew's; H. Das, University College; W. L. de Silva, Liverpool; Phyllis Decima Dixon, Royal Free; H. B. Dodwell, Cambridge and University College; Constance Maude Edwards, Liverpool; M. Edwards, St. Thomas's; W. Eldridge, London; S. Ghosh, Royal Free; Alice Mary Ley Greaves, Royal Free; E. G. Harris, London; A. H. Hilmy, St. Thomas's; C. V. Isard, St. Thomas's; N. R. Jenkins, Westminster; D. J. A. Lewis, London; A. G. F. McArthur, Cambridge and St. Thomas's; Ruby Eva McBirnie, Liverpool; J. G. McCann, St. Thomas's; D. G. Macpherson, University College; Ethel Mary Mathews, Sheffield; P. N. Menon, University College; R. S. Millar and H. Millett, Guy's; E. W. Mottau, University College; Annie Shortridge Mules, Royal Free; F. C. Odling, Cambridge and St. Thomas's; S. W. Page, St. Bartholomew's; A. V. Pegge, Cambridge and St. Bartholomew's; W. E. Powell, Charing Cross; S. H. de G. Pritchard, London; H. Ratnarajah, St. Mary's; F. N. Reynolds, St. Thomas's; S. Riddlough, Cambridge; Sophie Sarah Rosenberg, Royal Free; Helen Roth, Birmingham; H. Rowan, University College; J. F. Ryan, St. Thomas's; S. Sacks, London; Eleanor May Scarborough, Royal Free; K. L. Singer, Middlesex; B. L. Skeggs and P. A. Smuts, St. Bartholomew's; R. C. W. Staley, Guy's; C. M. Titterton, St. Bartholomew's; A. R. Tothill, Charing Cross; D. J. Valentine, London; J. A. van Heerden, St. Bartholomew's; J. Victory, Guy's; C. H. Warner and R. E. S. Webb, Middlesex; A. S. Westmorland, St. Mary's; A. Winfield, Cambridge and Liverpool; and E. B. Woolf, London.

Surgery.—E. Ahmed, London; R. D. Aylward, London; F. E. Benfix, Middlesex; J. A. Birrell, Cardiff and St. George's; A. G. Brett, Liverpool; W. B. Buer, Guy's; F. W. Chamberlain, Middlesex; Florence Marjory Edwards, Royal Free; J. S. Eloff, Cambridge and St. Thomas's; Eryl Glynne, Royal Free; J. Hale, Cambridge and St. Thomas's; Bertha Hinde, Royal Free; E. C. Hinde, Guy's; J. M. Hughes, Middlesex; Emily Catherine Lewis and Marguerite Frances Jane Lowenfeld, Royal Free; K. McFadyean, University College; H. M. Menage, St. Bartholomew's; A. K. Menon, Madras and London; P. D. J. Milanius, Ceylon and Middlesex; H. Morris-Jones, Liverpool; J. W. M. Nicholl, Cambridge and Middlesex; H. Palmer, London; E. R. Peirce, Birmingham; A. R. Poduval, Madras and St. Bartholomew's; H. J. R. Surrage, Cambridge and King's College; C. M. Titterton, St. Bartholomew's; G. H. Ward, Cambridge and St. Thomas's; and G. Zachariah, Madras.

Midwifery.—C. W. W. Armstrong, Guy's; E. B. Ash, Birmingham; K. E. Attenborough, St. Mary's; R. D. Aylward, London; R. W. C. Ball, Middlesex; E. R. Batho, St. Bartholomew's; G. E. Birkett, Cambridge and Manchester; J. W. Brash, St. Mary's; E. H. Bryant and A. Bulleid, Guy's; F. Cameron, Charing Cross; Annie Clark, Sheffield; W. E. L. G. Clark, St. Thomas's; B. S. Collings, University College; O. F. Conoley London; C. G. S. Corner, University College; Dorothy Trevor Dalntree, Royal Free; E. S. Davies, Westminster; W. L. de Silva, Liverpool; Phyllis Decima Dixon, Royal Free; C. L. Donne, Middlesex; F. B. Dutton, St. Thomas's; Constance Maude Edwards, Liverpool; Florence Marjory Edwards, Royal Free; M. Edwards, St. Thomas's; S. el D. A. El Daab, Cairo and St. Bartholomew's; J. S. Eloff, Cambridge and St. Thomas's; J. C. Gle, Guy's; E. H. Glenny and L. C. Goument, St. Bartholomew's; Lilian Maud Griffiths, Royal Free; A. G. Hewer, Middlesex; Bertha Hinde, Royal Free; E. A. Holmes, King's College; P. G. Horsburgh, St. Bartholomew's; J. F. Howells, University College; H. B. Jackson, Cambridge and St. Bartholomew's; M. Jackson, St. Barthomew's; G. H. Johnson, Middlesex; W. A. Jolliffe, St. Bartholomew's; A. K. I. Jones and J. W. Jones, Middlesex; H. C. C. Joyce, St. Bartholomew's; N. Kamchorn and C. H. Laver, Guy's; Ruby Eva McBirnie, Liverpool; K. McFadyean, University College; H. I. Marriner, St. Thomas's; H. Millett, Guy's; D. C. Mintzman, King's College; F. Morcos, St. Mary's; H. Morris-Jones, Liverpool; G. E. Mullins, Birmingham; J. G. Nel, Charing Cross; W. P. Nelson, Birmingham; G. Noott, Guy's; F. C. Odling, Cambridge and St. Thomas's; M. J. Panthaky, King's College; C. S. Parker, Charing Cross; Irene Grace Parsons, Royal Free; J. C. Pauw, London; R. W. Payne, Charing Cross; C. F. Rainer, London; C. G. J. Rayner, St. Bartholomew's; Joyce Baron Reed, Royal Free; Helen Roth, Birmingham; H. B. Russell and K. Sahib, St. Thomas's; M. Sarkies, Middlesex; J. J. Savage, St. Bartholomew's; H. M. Savery and W. M. Savery, Middlesex; Charlotte Annie Shields, Royal Free; A. T. Spoor, Cambridge and St. Thomas's; F. H. Stuttaford, St. Mary's; P. W. Symons, Middlesex; N. B. Thomas, St. Bartholomew's; J. A. van Heerden, St. Bartholomew's; G. Verghese, St. Andrews University; J. Victory, Guy's; P. E. Williams, St. George's; A. Winfield, Cambridge and Liverpool; and S. T. Wong, Guy's.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

—An extraordinary Comitia was held on May 10th, Dr. Frederick Taylor, the President, being in the chair. The following, elected to the Fellowship at the last meeting, were admitted to the College: Dr. R. H. Cole, Dr. D. N. Nabarro, Dr. H. W. Gardner, Dr. R. H. Miller, Dr. P. W. Saunders, Dr. W. E. Hume, Dr. H. MacCormac.—Licences to practise physic were granted to two candidates who had passed the required examination, their names not being included in the list submitted to the last meeting of the College.—A report from the Censors' Board concerning the will of the late Samuel Mathias Carl, advising the College to decline the bequest offered, was received and adopted after some discussion.—The Streatfield Research Fund Committee presented a report embodying a scheme for the administration of the Trust, which was adopted.—The Committee of Management having considered the proposal referred from the last Comitia concerning the suspension of the Regulations that students should attend systematic courses of lectures, reported as follows:—

> The Committee of Management beg to recommend to the Royal Colleges that, in consideration of the urgent conditions resulting from the war, Paragraph XIV., Clause 2 (*a*) and (*b*), and Paragraph XXI., Clause 1 (*a*) ,to (*g*), Section II. of the Regulations of the Examining Board in England, which require attendance on systematic courses of lectures, be not enforced for the present.[1]

This was agreed to.—A further grant of money was voted towards the expenses of the Committee of Reference.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

—An ordinary meeting of the Council was held on May 10th, Sir William Watson Cheyne, the President, being in the chair.—Mr. Ernest W. Hey Groves was introduced and the President handed to him a cheque for £15, the Jacksonian prize for the year 1916, together with a document declaratory of the award.—It was resolved to grant diplomas of Membership to 103 successful candidates.—In accordance with a report from the Committee of Management it was resolved:—

> That in consequence of (1) the depletion of the staffs of the hospitals and medical schools, (2) the reduction in the number of students, and (3) the amount of time necessarily devoted by students in their fourth and fifth years to practical clinical work owing to the shortage of resident medical officers, the regulations requiring attendance on systematic courses of lectures be not enforced for the present.[1]

The President reported that he had appointed Mr. William F. Haslam the representative of the College on the Medical Board of the University of Wales for three years.

At the Primary Fellowship Examination held on May 2nd, 3rd, and 8th, 30 candidates presented themselves, of whom 12 were approved and 18 were referred. The following are the names and medical schools of the successful candidates:—

Alberto Henrique Ferreira Bizarro, Lisbon University and University College; Reginald Stafford Foss, St. Thomas's; Lionel George

[1] The courses of lectures referred to are those on Anatomy, Physiology, Medicine, Surgery, Midwifery, Pathology, Pharmacology and Therapeutics, Forensic Medicine including Insanity, and Public Health.

Higgins, Cambridge and St. Thomas's; Thomas Ernest Victor Hurley, Melbourne; Roy Russell Kerr, Edinburgh and King's College; Vasant Ramji Khanolkar, University College; Fede Margaret Mackenzie, Royal Free; Kenneth Holl McMillan, St. Thomas's; Charles Dundas Maitland, St Thomas's; Maurice Marcus, London; Neil Frederick Sinclair, London; and Man Wong, St. Thomas's.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At a meeting of the College held on May 15th the following gentlemen, having passed the requisite examinations, were admitted Fellows: Marsham A'Beckett M'Carthy, Herbert Evelyn Allenson, John Henry Cobb, George William Gower, Edward Ratcliffe Holborow, Hugh John M'Caw, and Frederick Agar St. John.—The Bathgate Memorial Prize, consisting of bronze medal and books, was, after a competitive examination in materia medica, awarded to Mr. Len Philip Samarasinha.

At the examinations, just concluded, for the Diploma in Public Health (Triple Qualification) the following candidates were successful:—

First Examination.—Ella Ferrier Pringle, Tha Doe, Gladys Ward, Leopold Mandel, John Lewis Owen, Gladys Richarda May Violet Williamson, and Michael Wilson Symington.

Second Examination.—Gladys Ward and Ella Elphinston.

MEDICAL SOCIETY OF LONDON.—At the annual general meeting, held on May 14th, the following Fellows were elected to office:—President: Sir StClair Thomson. Vice-Presidents: Sir Anderson Critchett, Dr. A. E. Garrod, C.M.G., F.R.S., Dr. J. H. Stowers, and Mr. H. J. Waring. Treasurer: Dr. J. Mitchell Bruce. Librarian: Dr. A. F. Voelcker. Honorary Secretaries: Mr. Hugh Lett and Dr. Edmund Cautley. Honorary Secretary for Foreign Correspondence: Dr. H. R. Spencer. Council: Mr. D. Armour, Sir Robert Armstrong-Jones, Dr. F. F. H. Bateman, Sir John Broadbent, Mr. L. V. Cargill, Mr. H. W. Carson, Dr. E. A. Cockayne, Mr. Edred M. Corner, Dr. J. Fawcett, Dr. W. J. Fenton, Dr. B. E. Goff, Mr. Owen Lankester, Mr. J. D. Malcolm, Dr. F. W. Mott, F.R.S., Mr. C. J. Ogle, Mr. G. C. Parnell, Mr. D'Arcy Power, Dr. D. Lloyd Roberts, Mr. C. Ryall, and Mr. R. Jocelyn Swan.

INSANITY IN IRELAND.—An Irish correspondent writes: The report for 1915 of the Inspectors of Lunatics in Ireland, recently issued, is remarkable in that for the first time since 1865 there has been no increase in the number of insane under care in Ireland. There has, in fact, been a decrease of 77, the total number on Jan. 1st, 1916, being 25,103. Moreover, the decrease is to some extent due to a lessened admission rate, the decrease, however, being entirely among males. There was an actual increase among females. Although this is the first actual decrease recorded for many years, the rate of increase had for the past five years been considerably retarded. Thus the average annual increase from 1904 to 1914 was 218, but from 1909 to 1914 it was only 104. In proportion to the total population there were, in 1915, 573 insane per 100,000. It is noted that in 1·32 per cent. of the total admissions to asylums during the year the war was assigned either as the principal or a contributory cause of the insanity. Moreover, this cause appeared to affect women more than men.[1] During the year there were in the district asylums two deaths from suicide, two from misadventure, and three from injuries inflicted by fellow-patients. From the notes of the inspectors on the several asylums visited it is clear that in many of them there is much room for improvement.

DONATIONS AND BEQUESTS.—The King has sent a donation of £200 to King Edward VII. Hospital, Windsor, towards the extinction of a debt of £1925, and a lady has offered to give £1000 provided the balance of the debt is subscribed before the end of May.—By will the late Miss Sarah Jane Waddell, of Bridgwater, Somerset, bequeathed £500 each to the Bridgwater Nursing Association, the Bridgwater Hospital, the Devonshire Hospital, Buxton, and £100 each to the Queen's Hospital, Birmingham, Dr. Barnardo's Homes, and the Charity Organisation Society.—The late Mr. Samuel Bayley Verney Asser, of Westwood-place, Windlesham, Surrey, has left £500 for such hospitals in the City and County of London as the executors may select.—Miss Anna Pigeon, of South Side, Clapham Common, has left £300 each to the Clapham Dispensary and the Royal Surgical Aid Society.—The late Mrs. Harriet Stock Bradley, of Leamington Spa, has bequeathed £1000 to the Midland Home for Incurables, Leamington, and part of the residue of her estate to the Walsall and District Hospital and the Leamington and Warneford Hospital.—The late Mr. William Walmsley Simpson, of Winkley, Whalley, Blackburn, has left by will £1000 to the Blackburn Infirmary and £350 to the Oswaldtwistle Nursing Association.—After certain small bequests, the residue of the estate of the late Mrs. R. M. Acock, of Croydon, valued at £10,000, has been left to Guy's Hospital, Croydon General Hospital, the Cancer Hospital, Fulham, and the Hospital for Consumption, Brompton.—The late Mr. Charles E. Godfrey, of Southsea, has left by will 1000 shares in Chas. Godfrey & Co. in trust for the Royal Portsmouth Hospital.—Mr. R. F. Bolitho has given £1500 to the West Cornwall Infirmary, Penzance, to endow a bed to the memory of his late sister, Miss Sage Ley Bolitho.—The late Mr. T. R. Butcher, of Bath, has bequeathed £8000 to the British Red Cross Society.—By the will of the late Mr. Charles James Atkinson, of Bath, the British Home for Incurables, Streatham, will receive £1000, and the Royal United Hospital, Bath, and the Mineral Water Hospital, Bath, £500 each.

THE LATE DR. T. E. UNDERHILL.—We regret to record the death of Thomas Edgar Underhill, M.D., C.M. Edin., F.R.C.S. Edin., aged 62. He had practised for the last 27 years at Barnt Green in Worcestershire, having previously for four years practised at Bromsgrove, where he had succeeded the late Dr. Prosser. Dr. Underhill belonged to a well-known medical family, his father and uncle having been among the best-known practitioners in South Staffordshire, where their work and name are still continued. After taking his degree at Edinburgh in 1876, he joined his father in practice at Tipton, Staffordshire, where he remained for 10 years, holding at that time the post of surgeon to the Guest Hospital at Dudley. On moving to Bromsgrove he became medical officer to the school and surgeon to the local Volunteer Battalion of the Worcestershire Regiment, retiring with the rank of surgeon-major after 16 years' service. He also took an active part in local affairs, being vice-chairman of the School Board and bailiff of the Bromsgrove Court Leet. The activities of a large practice did not prevent him taking part in other public work. He was President of the Midland Medical Society, and latterly worked in connexion with the British Red Cross, being medical officer to the "Beaconwood" Convalescent Hospital for Wounded Soldiers. Dr. Underhill leaves a widow. Five of his sons are serving in H.M.'s Forces. He will be greatly missed by a wide circle of friends and patients.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Secret Session.

AT the conclusion of questions on Thursday, May 10th, and Friday, May 11th, the House of Commons sat in secret session.

Venereal Disease Bill.

The Venereal Disease Bill has passed through report in the House of Commons and been read a third time. In the course of a short debate on the motion for the third reading, which took place on Tuesday, May 15th, Mr. HAYES FISHER (Parliamentary Secretary to the Local Government Board) repeated his statement that there was no evidence that venereal disease was on the increase in this country, but the report of the Royal Commission had thrown a very powerful searchlight on the problem, and had shown the necessity for dealing with the matter by legislation. He hoped the Bill would do something towards providing a remedy for the disease, and would gradually diminish the number of those suffering from it. Some other speeches presented views which had previously been expressed in the proceedings on second reading and in Committee. Sir WILLIAM COLLINS expressed the hope that the Bill would accomplish something useful, but he criticised some of the provisions. The third reading was agreed to without a division.

HOUSE OF COMMONS.

WEDNESDAY, MAY 9TH.

The Rum Ration.

Answering Mr. L. HASLAM, Mr. MACPHERSON (Under Secretary for War) said: Rum is issued at the front at the discretion of the General Officer Commanding on the recommendation of the medical officer, and it is not proposed to interfere with this discretion. The method of distribution must obviously depend on the circumstances of each particular occasion.

THURSDAY, MAY 10TH.

Medical Re-examinations.

Mr. MONTAGUE BARLOW asked the Under Secretary for War with regard to the Military Service (Review of Exceptions) Act whether he would give instructions that in every case where a discharged man was required to present himself for examination under the Act his papers, and in particular his full medical history, should be before the board who held the examination.—Mr. MACPHERSON wrote in reply: This is already provided for by the existing recruiting regu-

lations, and steps are being taken to remind recruiting officers of their responsibility in ensuring that this regulation is strictly adhered to.

Body Shields for Soldiers.

Mr. MACPHERSON informed Mr. SNOWDEN that the question of the provision of body shields for soldiers had been considered, but no decision had been reached.

Spotted Fever at Chisledon Camp.

Mr. SNOWDEN asked the Under Secretary for War whether there was an outbreak of spotted fever at Chisledon Camp, Swindon, and whether any deaths had taken place from this cause.—Mr. MACPHERSON replied: I am informed that since April 1st last 12 cases have occurred in this camp, and of these three have died.

MONDAY, MAY 14TH.

Prevention of Contagion from Venereal Disease.

Sir ERNEST LAMB asked the Under Secretary for War whether any steps were being taken to prevent venereal disease being communicated to men sleeping in blankets that had previously been used by persons suffering from such complaint.—Mr. MACPHERSON replied: Yes, sir. Under the regulations blankets which may have been exposed to infection are soaked in cresol solution before being washed. I have no reason to suppose that this precaution is being neglected.

Medical Attendance on Soldiers' Widows.

Major CHAPPLE asked the Pensions Minister what provision was to be made for the medical treatment of widows and orphans of sailors and soldiers during and after the war.—Mr. BARNES answered: The National Health Insurance Commissioners are now considering at my request how the medical treatment of widows and orphans of sailors and soldiers killed in the present war can be best provided. My honourable friend is doubtless aware that the whole question of medical service will be further dealt with in connexion with the proposal to establish a Ministry of Health.

Supply of Artificial Limbs.

Answering Major CHAPPLE, Mr. BARNES said: The total number of artificial limbs supplied from the beginning of the war up to the end of last month was 8805. The total public expenditure during this period on the supply and renewal of artificial limbs and other surgical appliances was £127,293.

TUESDAY, MAY 15TH.

Medical Men in Combatant Units.

Answering Mr. WATT, Mr. MACPHERSON said: Steps have been taken to withdraw medical practitioners who are officers of the fighting forces. All medical practitioners who are known to be non-commissioned officers and men are invariably offered appointments as officers in the Royal Army Medical Corps if fitted to hold His Majesty's commissions.

WEDNESDAY, MAY 16TH.

Volunteer Field Ambulances.

Sir W. COLLINS asked the Under Secretary for War whether the proposals for the formation of volunteer field ambulances which were under consideration with a view to an early settlement on April 3rd had now been completed; and what were the arrangements which had been made for an ambulance service or for regimental medical officers in connexion with the Volunteers.—Mr. MACPHERSON wrote in reply: The formation of field ambulances for Home Service on a Volunteer basis has been approved and offers of service have been invited from certain counties. If the result proves satisfactory the scheme will, I hope, be extended. The appointment of medical officers is proceeding, but it is not free from difficulty owing to the demand for medical officers for service overseas and for full-time service in this country, which has necessitated the imposing of certain restrictions as to age upon candidates for Volunteer appointments.

BOOKS, ETC., RECEIVED.

ARNOLD, EDWARD, London.
Introduction to Special School Work. By Marion F. Bridle, L.L.A. With Foreword by G. A. Auden, M.A., M.D., M.R.C.P. 3s. 6d. net.

SALISBURY GENERAL INFIRMARY.—House Surgeon, unmarried. Salary £150 per annum, with board, &c.
SHEFFIELD ROYAL HOSPITAL.—Casualty Officer. Salary £130 per annum Assistant House Surgeon. Salary £120 per annum, with board, &c.
SHEFFIELD ROYAL INFIRMARY.—House Physician. Salary £120 per annum, with board, &c.
WIGAN, ROYAL ALBERT EDWARD INFIRMARY AND DISPENSARY.—Medical Officer to take charge of Out-patient Department. Salary £250 per annum, with board, &c.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Enniscorthy (Wexford) and at Redruth (Cornwall).

Births, Marriages, and Deaths.

BIRTHS.

CARMICHAEL.—On May 10th, at Atholl-crescent, Edinburgh, the wife of Lieutenant Norman Scott Carmichael, R.A.M.C., of a daughter.
COOK.—On May 12th, to Evelyn Russell and Joseph Basil Cook, M.D., D.P.H., R.A.M.C., of the Infirmary, Isleworth—a daughter.
FAIRLIE.—On May 12th, at Mecklenburgh square, W.C., the wife of William M. Fairlie, M.D., of a daughter.
MCDOUALL.—On May 8th, at Red Bank, Hornsey-lane, Highgate, N., the wife of J. C. S. McDouall, West African Medical Staff, of a daughter.
MAIDMENT.—On May 8th, at Harleston, Norfolk, the wife of Frederick N. H. Maidment, M.B., F.R.C.S. Edin., of a son.
POULTON.—On May 7th, at Wykeham Cottage, Woldingham, Surrey, to Elfrida, wife of E. P. Poulton, M.D., F.R.C.P.—a son.
SETH-SMITH.—On May 11th, at Tower House, Bildeston, Suffolk, the wife of Douglas Seth Smith, M.R.C.S., L.R.C.P.—a daughter.

MARRIAGES.

FRASER—CHARD.—On May 15th, at Chichester, by the Rev. J. B. Sherrin, assisted by the Prebendary Rickard, vicar of the parish, Major Alexander Edward Gordon Fraser, R.A.M.C., only son of the late Donald Alexander Fraser, M.D., of Totnes, Devon, to Dorothy Louise Josephine, elder daughter of the late R. A. S. Chard, of Magnolia, West Tarring, Worthing.
HOPKINS—MILES.—On May 12th, at St. Mary's, Prittlewell, Lionel Gordon Hopkins, M.D., to Dorothy Bessie Miles.
KEYNES—DARWIN.—On May 12th, at St. Bartolph's, Cambridge, Captain G. L. Keynes, M.A., R.A.M.C., to Margaret Elizabeth, younger daughter of the late Professor Sir George Darwin, K.C.B.

DEATHS.

FAIRWEATHER.—On April 29th, at Forest Hill, Beaumont, Jersey, Surgeon-General James Fairweather, M.D., F.R.C.S., Indian Medical Service (retired), aged 89.
FOWLER.—On May 3rd, at Essington House, Hereford, John Bucknill Fowler, M.R.C.S. Eng., and late of Kobe, Japan, aged 55.
RAE.—On April 15th, reported missing, believed drowned, James Rae, M.A., M.D., Lieutenant, R.A.M.C., who was on board the torpedoed troopship *Arcadian*.
RYLEY.—On May 4th, Charles Ryley, Major, R.A.M.C.
UNDERHILL.—On May 8th, at Dunedin Barntgreen, Worcestershire, T. Edgar Underhill, M.D., F.R.C.S. Edin., F.R.S. Edin., aged 62.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

TOBACCO.

To the Editor of THE LANCET.

SIR,—As there is at the present time much interest in the subject of tobacco, in consequence of increased taxation, the following statistics of its production may be useful to your readers. In the United States, in 1901, the acreage under tobacco was 1,039,199, the number of pounds produced 818,953,373, and the value in dollars 58,283,108. Ten years later the following were the figures: 1,013,000 acres, 905,109,000 lb., $85,210,000. The Americans estimate that the total production by tobacco-growing countries is roughly 2053 million pounds, of which it is claimed practically 1100 million pounds are produced by the United States and the remainder as follows: Cuba, 45 millions; Mexico, 35 millions; Santo Domingo, 33 millions; Argentina, 31 millions; Brazil, 75 millions; Hungary, 160 millions; France, 37 millions; Germany, 64 millions; Russia, 201 millions; Turkey, 50 millions, but including Asiatic Turkey 100 millions; Java, 84 millions; Sumatra, 45 millions; and Japan, 92 millions.

An English estimate is that the total production amounts to 2,756,000,000 lb., produced chiefly by the following countries: United States, 1,113,400,000 lb.; India, 450,000,000 lb.; Russia, 200,000,000 lb.; Austria-Hungary, 184,000 000 lb.; Netherlands' East Indies, 128,600,000 lb.; Japan, 93,000,000 lb. The value of the tobacco imported by the United Kingdom is placed at about £6,350,000, before the war, but the value of the tobacco exported was £2,600,000. The import for 1915 is placed at £8,550,000, and the export at £3,790,000. The consumption of tobacco in France, according to French figures, is 39,500,000 kilogrammes (about 86,900,000 lb.) In 1911 the Union of South Africa produced 14,961,199 lb. In Canada in 1910 the production was 17,604,917 lb. from 19,194 acres. In Ireland from 1887 to 1904 experiments were carried on in County Meath and in 1900 and 1901 in several other counties. In 1904 20 acres were planted. The results proved satisfactory, and tobacco is now grown in Meath, Louth, Wexford, King's County, Kilkenny, and Cork, about 150 acres altogether. In England a small quantity was grown a few years ago in south-west Norfolk. Sixty years ago 20 per cent. would have had to be added to the weights given for adulteration, such as dock, rhubarb, coltsfoot, chicory, endive, oak, elm, and even maize and sunflower leaves. These are bare facts, and I do not propose to draw any deductions from them, but they undoubtedly have a medical bearing as well as a commercial interest.

I am, Sir, yours faithfully,

May 8th, 1917. PETUN.

HERB-GROWING IN THE WEST OF ENGLAND.

A LARGELY attended public meeting was recently held at Totnes (Devon) in connexion with the National Herb-Growing Association. The organiser for Devon (Mr. C. Walkey) reported that the society was founded in 1915, and had now over 2000 members. Collections of herbs had been arranged over an area of 250,000 acres in Somerset, including all Exmoor. Drying sheds were to be erected at Torquay and Taunton. The society would require large quantities of foxglove seeds and dandelions, as well as of belladonna roots. The association had received one order for £2000 worth of medicinal herbs, and it was estimated that the trade in these plants was worth not less than £200,000 a year.

NORTHERN TERRITORIES OF THE GOLD COAST.

ACCORDING to the report on the Northern Territories for 1915, recently received at the Colonial Office, the health of the European population, consisting almost exclusively of Government officials, was fairly good, and there was no death. The health of the native officials was also fairly good. The prevalent disease was malaria.

The Census completed in 1911 gave an estimated population of 361,806 to the Northern Territories, with a computed area of 31,100 square miles—an average of 11·6 persons to the square mile. In spite of the heavy infant mortality it is considered that the population at the present day is greatly in excess of that shown by the Census, as there is reason to believe that in the North-Eastern Province not more than two-thirds of the inhabitants were enumerated. No serious outbreak in epidemic disease occurred during the year. Anthrax was reported to have broken out at the village of Zongiri in the Bawku district, where eight natives died, but the medical officer who visited the village found that it had not spread, and that there were no further cases of infection. Leprosy is not on the increase, and, while uncommon in the Southern and North-Western Provinces, is of more frequent occurrence in the North-Eastern Provinces. The natives look upon it as "a visitation of Allah," but say that it shows no signs of spreading and are generally averse to compulsory isolation. The medical officer at Salaga states that the

death-rate in that district for the year was 33·25 per 1000. It is considered that much of the disease among the native population is caused by the poor water supply, to improve which efforts are now being made.

There are four Government hospitals in the Southern Province, three in the North Western Province, and four in the North-Eastern Province. The attendance of out-patients at these hospitals increases yearly, but the natives object to the restrictions placed on them as in-patients, and only those suffering from the worst complaints can be persuaded to remain in hospital for any length of time. 2226 out-patients and 115 in-patients were treated at the Tamale Hospital during the year, 972 and 14 at Saliga, 473 and 22 at Bole, 217 and 8 at Lorha, 589 and 22 at Gambaga, and 319 and nil at Navarro respectively.

THE USE OF MAIZE IN BREAD.

To the Editor of THE LANCET.

SIR,—My experience among my patients is that the mixed flours agree well if the addition of barley or oatmeal is made, but if maize is mixed, within a few days consumers complain of colic, sometimes of a severe character. I have suggested to patients who have consulted me in these circumstances that they discontinue eating the particular flour they are consuming and purchase either wholemeal or a flour which they are certain only contains barley or oats as an addition—not maize. In every case where this has been done the pain has ceased. This result of eating flour and maize was to be expected, and is well known to anyone who has resided long in the East, where the adulteration of wheaten flour with maize is common. As it is necessary for every worker to keep himself or herself as fit as possible, would it not be advisable to have each sack branded with the particular kind of admixture, so that all purchasers could buy the one which agreed with them best?

I am, Sir, yours faithfully,

May 7th, 1917. ANGLO-INDIAN.

MEDALS FOR SERVICE IN THE ARMY AND NAVY.

LONG lists of honours call repeated attention to medals and decorations. A few years ago a guide to the Department of Coins and Medals in the British Museum was printed by order of the trustees, and was intended for those who while taking an intelligent interest in the subject were not inclined to devote much time or attention to any particular class of medals or coins. The following excerpt is interesting:—

> The exhibition of English medals is completed by a selection of military and naval decorations. The custom of presenting these decorations is of very recent date, and it may be said only to have been established during the reign of Queen Victoria. As already mentioned, it is supposed that some of the Armada medals were intended for decorations, as they still bear chains for suspension. During the Civil War it is also supposed that the numerous royalist and parliamentarian badges were intended to be worn by the followers of both sides; and we have distinct evidence that during the Commonwealth decorations were ordered both for the Navy and the Army. During the whole of the eighteenth century decorations were only occasionally granted, and then in most cases singly; and the famous victories of the Nile and Trafalgar received no official recognition. It is very doubtful whether the Culloden medal was ever granted, as there is no evidence of an order to that effect; and besides it is excessively rare, only a few specimens in gold, silver, and copper being known. During the Peninsular War some special decorations were issued to the officers of both services, but the East India Company acted in a much more liberal spirit and awarded medals to men of all ranks who were in its service for several of the more important campaigns. The first medal for general distribution issued by authority in this century was that given for the battle of Waterloo. It was conferred by order of the Prince Regent upon every officer, non-commissioned officer, and private present at that battle, but no general acknowledgment was made for all the brilliant engagements in the Peninsular War till 1847, when a medal was issued "for military services" between the years 1793-1814. At the same time a corresponding medal "for naval services" was ordered to be struck for all naval engagements. Since that date medals have been awarded for every campaign, as well as others for "distinguished service," for "meritorious service," for "long service," special acts of bravery, &c.

Three useful books may be mentioned which afford further information:—"War Medals and their History," by W. Augustus Stewart (London: Stanley Paul and Co. Price 12*s.* 6*d.*); "Naval and Military Medals," by Lieut.-Commander Taprell Dorling (London: Geo. Philip and Sons. Price 2*s.*); and "British and Foreign Orders, War Medals and Decorations," by A. A. Payne, L.R.C.P., M.R.C.S. (Published in 1911. Price 31*s.* 6*d.*). Gale and Polden's books published at Aldershot, on medals, buttons, and ribbons, are well known.

J. B. C.—Appointments to venereal treatment centres are made by the authorities of the hospitals to which the clinics are affiliated but it is probable that the arrangements will be modified after the first year of working or at the conclusion of the war, when some of these appointments, especially in the provinces, may be directly in the gift of the Local Government Board. All appointments are now part-time, but some may become whole-time ones, and if the Ministry of Health comes into being there will probably be regular organisation.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, May 21st.

ODONTOLOGY (Hon. Secretaries—F. R. Smyth, F. N. Doubleday, J. Howard Mummery): at 5.30 P.M., at the Royal College of Surgeons, Lincoln's Inn Fields.

Annual General Meeting.—Election of Officers and Council for 1917-1918.

Exhibition of Specimens, &c.:

Professor Arthur Keith, F.R.S., and Mr. J. F. Colyer will demonstrate specimens recently added to the Museum.

Tuesday, May 22nd.

MEDICINE (Hon. Secretaries—Charles R. Box, W. Cecil Bosanquet): at 5.30 P.M.

Annual General Meeting.—Election of Officers and Council for 1917-1918.

Thursday, May 24th.

BALNEOLOGY AND CLIMATOLOGY (Hon. Secretaries—Chas. W. Buckley, J. Campbell McClure): at 5.30 P.M.

Annual General Meeting.—Election of Officers and Council for 1917-1918.

Report of Council.

Friday, May 25th.

STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—A. S. Blundell Bankart, E. A. Cockayne, C. P. Lapage): at 4.30 P.M.

Annual General Meeting.—Election of Officers and Council for 1917-1918.

Cases will be shown.

EPIDEMIOLOGY AND STATE MEDICINE (Hon. Secretaries—William Butler, Major Greenwood, jun.): at 8.30 P.M.

Annual General Meeting.—Election of Officers and Council for 1917-1918.

Paper:

Miss Muriel Robertson: Recent Researches into the Etiology of Typhus.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

THURSDAY.—3 P.M., Prof. W. Bateson: The Chromosome Theory of Heredity and the Alternatives. (Lecture II.)

FRIDAY.—5.30 P.M., Mr. J. Barcroft: Breathlessness.

ROYAL INSTITUTE OF PUBLIC HEALTH, Lecture Hall of the Institute, 37, Russell-square, W.C. 1.

Course of Lectures and Discussions on Public Health Problems under War and After-war Conditions:—

WEDNESDAY.—4 P.M., Lecture VI.:—Sir C. Arthur Pearson, Bart.: The Re-education and Training of Disabled Combatants. Followed by a discussion.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, May 16th, 1917.

Date.	Rain-fall.	Solar Radio in Vacuo.	Maximum Temp. Shade.	Min. Tem.	Wet Bulb.	Dry Bulb.	Remarks.
May 10	...	101	65	46	51	54	Cloudy

,, 16	...	81	54	47	46	49	Overcast

Other information which we have been accustomed to give in these "Readings" is withheld for the period of the war.

The following journals, magazines, &c. have been received:—Revista Clinica, Veterinary Review, Journal of State Medicine, Revue de Chirurgie, Medical Review, Midland Medical Journal, Revista de Medicina, Annaes Paulistas de Medicina e Cirurgia, Boletin de Cirurgia.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.*

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C. 2.

MANAGER'S NOTICES.

ALTERATION IN THE PRICE OF "THE LANCET."

INCREASED war expenses and cost of production necessitate an increase of the price of THE LANCET. Commencing with the new year, the price was raised to 8*d*. The rates of subscription remain as revised in October.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C. 2, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given on page 6.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied.

Communications, Letters, &c., have been received from—

A.—Mr. W. Aston, Coventry; Mr. J. E. Adams, Lond.; Messrs. Scott Armstrong and Co., Lond.; Messrs. Allen and Hanburys, Lond.; Messrs. W. Abbott, Lond.; Messrs. Arnold and Sons, Lond.; Ancoats Hospital, Manchester, Sec. of; Mrs. Appleyard, Bradford.; Dr. Manuel na Rocha Amorim, Rio Man, Entre os Rios.

B.—Messrs. S. H. Benson, Lond.; British Medical Association, Lond., Deputy Medical Sec. of; Miss A. E. Blair, Markinch; British Drug Houses, Lond.; Bootle Borough Hospital, Hon. Sec. of; Board of Agriculture and Fisheries, Lond.; Messrs. W. H. Bailey and Son, Lond.; Mrs. E. Black, Campsie Glen; Miss A. M. Annual Oration
ON
THE CAMPAIGN AGAINST SYPHILIS.

Delivered before the Medical Society of London, May 14th, 1917,

BY SIR WILLIAM OSLER, BART., M.D., F.R.S.,
REGIUS PROFESSOR OF MEDICINE, OXFORD.

MR. PRESIDENT AND GENTLEMEN,—With the flotsam and jetsam of the sale-room there came to my library the other day a book for the times, with the title "A Discourse of Constancy ..... written in Latin by Justus Lipsius. Containing Comfortable Consolations, for all that are afflicted in Body, or Mind. London. 1654." To have known of the "Discourse" through two admirable articles by Basil Anderton, of Newcastle,[1] gave an added welcome to Humphrey Moseley's 12mo. "in the original state."

In the dialogue the two friends discuss the miseries of the age, which had made the Low Countries almost as desolate as they are to-day, and the great Louvain Professor a homeless wanderer. To the despairing Lipsius his friend urged that "equal calamities and far greater had already fallen on the race," and that after all it was the lot of man, his destiny, and that cities and people owe their ruin "by Commission of Providence." As a tonic to their constancy they rehearse through many chapters the wonderful slaughters, the strange cruelties, the plagues and famines and rapines; and the conclusion reached was that Good comes out of Evil, and that the righteous are never forsaken. Having accepted this comfortable consolation, hard for us to read anywhere except on the title-page of the book, our neo-Stoical friends went to dinner!

THE CONQUEST OF THE GREAT INFECTIONS.

The past three years have seen the slaughter of man by man on a scale heretofore unknown except in the lively imagination of the Chronicler of the Kings of Israel. On the illustrated title-page of the little book, Fate and Necessity beam from the sky dispelling the clouds and mist, and the light of Providence shines on the figure of Constantia. To us in these dark days comes a consolation denied to Lipsius and his friend. They did not realise as we do, that it is Apollo, not Mars, who slays most in war, that nature in the form of disease is more fatal to man than man with his weapons. The needless deaths of Peace far exceed those of the most disastrous wars. More people died of plague in two years in India than have been killed on both sides since the great war began. In 1915, while nine of our soldiers abroad died every hour to save their country 12 babies died at home in the same time, to the scandal of their country.

The knowledge of nature's laws has enabled men to devise really magnificent ways of wholesale butchery; yet with a delicious inconsistency the same knowledge has taught him the science of her ceaseless warfare through disease, and has enabled him to win the greatest victory in the history of humanity. Even in war time man displays just as much hostility to a hostile nature as he does to the enemy in the field. Bitter experience has shown him that disease is more fatal than powder and shot. The new knowledge has enabled him for the first time to reverse the ratio between bacilli and bullets. Full details are not to hand for the Allied Forces, but we know that the destructive pestilences have played a minor, not as heretofore the major, rôle. And it has been the same in the German armies in which the deaths from disease have been about 1 to 15 killed and died of wounds.

The story of the conquest of the great infections is the brightest single chapter in the history of science. The humanitarian aspect appeals to our better feelings, and hopes for the betterment of the race have been centred about health and homes and habits. There is a fly in the amber of course, and the vision is blurred (narrowed, indeed, to darkness!) as one looked in two directions—towards cancer and towards venereal disease. In choosing a subject for my address I could not let the opportunity slip of lending the weight of this ancient and honourable society to anything I might say upon the great awakening that has taken place with regard to syphilis and gonorrhœa. Among infections they stand alone. Against all others man wages a keen warfare. They present the remarkable and subtle combination of man and nature in an incessant and successful propaganda against the health of the nation. The report by Dr. R. W. Johnstone to the Local Government Board, 1913, and the report of the Royal Commission embrace every aspect of the question.

STATISTICAL DATA.

I propose to touch upon only two points—the importance of the enemy and the possibility of a successful campaign. I had the inestimable advantage of early professional association with a hero-worshipper. Dr. Palmer Howard, my teacher and for ten years at Montreal my revered colleague, was a man of keen intellectual attachment. Wide-awake when the dawn appeared, he saw with remarkable clearness the immense possibilities of preventive medicine under the guidance of such men as Chadwick, Budd, Simon, Farr, Ward Richardson, Buchanan, and Russell. When not talking of Bright and Addison, of Stokes and Graves, he was lauding these men, their ways, and their works. Important literary events were the arrival of Dr. Farr's Report and the Report of the medical officer of the Local Government Board, as they furnished ammunition for the year, and it was my privilege, if not always my pleasure, to dig out statistics of the various diseases or to abstract some special article. This, you may think somewhat irrelevant, statement is preliminary to an excursion I am about to ask you to make with me, not over unpathed waters, but through the familiar pages of the Registrar-General's Report—the just-issued volume for the year 1915. Custom has not made stale the awe experienced in the contemplation of its long rows of figures, the mystery of the position of the dots, and of such new expressions as standardised rates. And let me add a warning. No author of my acquaintance has been so uniformly unhappy as myself in dealing with statistics. And I have tried so hard! But there is scarcely a percentage in my Text-book that has not been challenged, and corrected, from various sources more than once. Like Lucian, then, in introducing his Vera historia, it may be well to solicit at the outset my hearers' incredulity.

The first thing to arrest attention in Sir Bernard Mallet's big Blue-book is the absence of all reference to venereal disease in the "Review of the Vital Statistics for the Year 1915," by Dr. T. H. C. Stevenson. Of 18 causes of death specially discussed, all but three belong to the infections, of which tuberculosis, pneumonia, and cancer[2] head the list—not a word about syphilis! For the report of 1912 Dr. Stevenson prepared a special discussion for the Royal Commission on Venereal Disease, and the difficulties of the whole subject, from the statistical standpoint, were exposed. The truth is, syphilis has been, and remains, the despair of the statistician. Trustworthy data are not forthcoming. Even in death a stigma is associated with it, and the returns are everywhere but under the special caption of the disease itself. Among the 11 causes of infant mortality during the first year syphilis is not mentioned, though on p. xxii. it is twice alluded to casually—the only place in which the word occurs in the 46 pages of the review! This is no reflection on Dr. Stevenson who works with material furnished by the profession.

Where, then, do venereal diseases appear? At p. 142 (International List No. 37) syphilis is stated to have been responsible for 1885 deaths at all ages, and other venereal disease for 61. Not a very heavy bill, and of the 1885 deaths, 1162 were under a year, 1277 under five years. Of the ten best killers among the infections (exclusive of the motley group of diarrhœal diseases of children) syphilis comes last. In order of potency they are (I give the round numbers), tuberculosis, 54,000; pneumonias, 49,000; cancer, 40,000; measles, 16,000; influenza, 10,000; whooping-cough, 8000; diphtheria, 6000; scarlet fever, 2400; cerebro-spinal fever, 2000.

REDUCTION OF TYPHOID FEVER.

But, Mr. President, I cannot pass these dry figures without a digression. To find syphilis among the ten great

[1] A Stoic in his Garden, and Justus Lipsius. The Library, 1915 and 1916.

[2] I put cancer with the infections to use its mortality rates.

infections may cause surprise, but this is nothing to the astonishment at the absence of what has been in so-called civilised countries the very David among infections, typhoid fever—a paltry 1400 deaths! a rate of 35 per million. For 40 years physicians everywhere have consulted these reports for the statistics of this disease as the sanitary index of the most sanitary country in the world. Where and how was this great victory won? Where do you suppose? In a Government office—of all places! At the Local Government Board—of all places! and by a group of Government officials—of all men! by Simon, and his successors! Staff work, team-work, organised administration, have solved one of the greatest of the problems of public health.

To realise the magnitude of the victory one must have lived and moved and worked year by year in typhoid-stricken countries—helpless and hopeless without proper sanitary laws, or without the power to enforce them. To have succeeded within the memory of some who hear me in reducing the mortality of typhoid fever from between 700 and 800 per million living to the low figure 35 per million is one of the decisive battles of humanity. Conditions in this country have become so healthy that even with hundreds of thousands of recruits at the most susceptible age concentrated in camps the death-rate from typhoid disease has been the lowest in our history—and there is the added triumph of an enteric-free army in France. Inoculation has done much; but the conquest of enteric fever in this country was won by honest sanitation, carefully directed from a centre by experts, and by Government experts.

Mr. President, here, if ever, we may say with Simonides, "The State is a man's teacher," and for the benefit of the timid Ionian individualist we may add Plutarch's comment—that this lesson is only learned through many a bitter struggle and experiences. The immediate purpose of this digression will appear later in my address. Let us now return to the report.

GONORRHŒA AND RACE CONSERVATION.

Content at this stage the superficial reader will have a very erroneous idea of the position of venereal disease in the nation's life; but before going deeper into its pages let me recall a few pathological and clinical details. Among the infections gonorrhœa and syphilis stand out as the great race poisons. No other germs act in precisely the same way. The gonococcus is not a great destroyer of life; the figures given for 1915 convey the truth, only some 61 deaths. This tallies with clinical experience, as the fatal complications are very rare. But the gonococcus is the greatest known preventer of life—in fact, one of its cruel properties is to sterilise a very considerable proportion of its hosts. To realise the ravages of gonorrhœa, do not consult the Blue-books or the text-books, but study the reports of the gynæcological clinics and hospitals for diseases of women. As high as 25 per cent. of the major operations may be for gonorrhœa complications, which are among the commonest sources of chronic ill-health. Conservative estimates place the percentage of sterility in women due to gonorrhœa at 50. A large majority of these women are innocent victims of infection, often innocent infection, by husbands who thought themselves free from all traces of what they regarded as a harmless indiscretion of youth, and who could have been cured under a proper system of control treatment. Then the complicating epididymitis in the male is a common cause of sterility. One recalls the dictum of Noegerrath—the founder of our modern knowledge of gonorrhœa in the female—90 per cent. sterile women have husbands who have had gonorrhœa.

From the standpoint of race conservation gonorrhœa is a disease of the very first rank, and costs the country annually thousands of lives. With 30 to 40 per cent. of all the cases of congenital blindness, with the chronic pelvic mischief in women, and with the unhappiness of sterile marriages—with these and many minor ailments scored up against it, we may say that while not a killer, as a misery producer Neisser's coccus is king among the germs.

SYPHILIS.

The spirochæte of syphilis is easily the most notable among germs. A protozoon—it is the only protozoon, indeed, it is the only germ of world-wide dominion, irrespective of race or clime. From its well worked out biology, just two points suffice for our present purpose. The first, in some ways the most important single feature in its history, is the frequency of the transmission from parent to child. Congenital tuberculosis—how rare! Congenital pneumonia—unknown!—in fact, a killing transmission in the great infections is very rare. In syphilis it stands out less as a biological peculiarity than as a fact of supreme importance in the national health. The spirochæte may kill the child in utero, a few days after birth, or within the first two years of life, or the blighted survivor may be subject to innumerable maladies.

Stillbirths.

The stillborn are at last to be numbered. Until now they have remained the "hidden untimely births," to use the language of Job. Sir Arthur Newsholme estimates them at close upon 100,000.[3] What percentage of these deaths are spirochætal we do not know. This we do know, that syphilis is perhaps the most common cause of abortion, and that in examinations which have been made in large maternity hospitals more than 25 per cent. of the stillborn have been found infected. In this stage of big figures we can afford to be liberal, so let us reject the 80, or even the 50, per cent. of some estimates and let us put the "untimely hidden births" due to syphilis at 25 per cent. and tally them at, say, 20,000 for the year 1915.

Have we any data to justify these figures? I have looked through a great deal of literature, and was not a little pleased to find from my old hospital by far the most satisfactory information. Let me state that the obstetrical department of the Johns Hopkins Hospital was begun in a very quiet way. We put a good man in charge, Dr. Whitridge Williams, who has had first-class assistants, whole-time men, and a method of teaching which has enabled him to get a great deal of work out of his students. The result has been the output of valuable knowledge and the collection of a body of experience which bears directly upon the question before us. Of the first 10,000 cases in the clinic there were 705 fœtal deaths—i.e., from the seventh month on—7·05 per cent. In all cases the placenta was examined as well as the fœtus. "By far and away the most common etiological factor in the producing death in the fœtus is syphilis," responsible for 26·4 per cent. in the series. This, too, is a low estimate, as at least 53 of the 127 macerated fœtuses were probably syphilitic, though this could not be determined microscopically. I purposely refrain from quoting the statistics, also of 10,000 cases, of the Sloan Maternity, New York, from which the syphilitic are excluded. The small but very thoroughly worked out details of 500 cases by Dr. Slemons, of Yale Medical School, give 26 per cent. An investigation is in progress in London for the Local Government Board, and I am allowed to quote the figures to date, which give only 44 positive cases in 300—a much lower percentage than I have found elsewhere. A 20 per cent. estimate would, I think, be reasonable.

Infantile Mortality.

In 1915, of 800,000 children born, 90,000 died within the first year, the lowest number yet recorded. Add this heavy loss to the intra-uterine deaths, and it makes stock-raising for the human animal a very poor business. I have no time to discuss (but I may offer congratulations on) the efforts to lower this early death-rate by Mr. Broadbent, of Huddersfield, and by his colleagues in the great child-saving work they are doing for the nation. The reports on the physical welfare of mothers and children by Dr. E. W. Hope and Dr. Janet Campbell, just issued by the Carnegie United Kingdom Trust, will prove a boon and a blessing to sanitary workers.

Of what did these 90,000 children die? First let us note that about one-fifth of these died within the first week and a fourth within the first month. Ten causes are mentioned: whooping-cough; other common infections; diarrhœa and enteritis; premature birth; congenital defects; atrophy, debility and marasmus; developmental and wasting diseases; tuberculous diseases; convulsions; bronchitis and pneumonia; and then other causes. Again, the interest in this list centres in what is not there! Shades of Fracastorius! Syphilis is not even mentioned! When I was a pathologist and physician to an infants' home, we did not have—nor did we need!—Schaudinn or Wassermann or Noguchi to tell us of what 95 per cent. of infants died during the first month. Jonathan Hutchinson and Parrot and Diday and Fournier had told us that. The Registrar-General cannot go behind

[3] Report on Child Mortality, 1916, p. 8.

his returns, but it is worthy of comment that in Dr. Stevenson's discussion on the causes of infant mortality syphilis is only mentioned twice (p. xxii.), and that casually. When we turn to the total deaths from syphilis then we do get light, as among the 1885 deaths 1162 were under 1 year, 1277 under 5 years, but these figures are far below the mark. Careful work is in progress to determine the number of deaths within the first year from syphilis, and we shall not be far wrong in placing the figure at between 15,000 and 20,000. Dr. Helen Y. Campbell, in charge of the Bradford Infants' Clinic, reports for 1915 34·30 per cent. with the clinical features of syphilis among the 207 deaths in 3010 infants under one year.

WIDESPREAD MANIFESTATIONS OF THE SPIROCHÆTE.

The second point in the biology of the spirochæte is a peculiarity it shares with many other parasites of resting dormant in the body for years. As a rule such germs, even while retaining their virulence, do little or no damage. Not so the spirochæte, whose capacity to work evil is not to be measured by years. Since Schaudinn's great discovery there is a sharper point to Sigmund's oft-repeated aphorism, "Syphilis is the worm that never dieth." *Venus impura* is a hard mistress. Venus of the long arm she should be called, as 10, 20, 30, even 40 years from the date of infection the book bills are rendered, and she wrings the uttermost farthing out of her poor victims. One plain outcome of all recent work is that the untreated or the half-treated syphilitic is a bad life. No insurance company to-day will take a man who has a Wassermann reaction. So widespread are the manifestations of the spirochæte in the body that there is truth in the paradox I was in the habit of telling my students, Study one disease, study syphilis thoroughly and you take a knowledge of all others on the way—general medicine, nearly all surgery, and certainly all the specialties.

But I see an incredulous look on some faces, and I hear the whispered comment—'tis heard often enough! "Where is all this syphilis? It does not come my way." Yes it does. The syphilis we see but do not recognise everywhere awaits diagnosis, so protean are its manifestations. My colleague at the Johns Hopkins Hospital, Lewellys Barker, in a recent paper enumerates 19.[4] A good test of the importance of a disease is to take the 37 volumes of the two series of the Index Catalogue of the Surgeon-General's Library, Washington, in which is indexed practically all medical literature between 1880 and 1917. In Vol. XVII. of the second series issued in 1912 are 207 double-columned pages of reference, against 117 pages in Vol. XIV. of the first series in 1893. No other single disease except tuberculosis has so much space devoted to it.

Syphilis illustrates the truth of the axiom that "Men do not die of the diseases that afflict them." Look up and down the columns on pp. 138–167 of the Report, and except in the figures I have already given there is no reference to syphilis, and if from the 1885 deaths you take out 1277 before the fifth year, there is left the apparently comforting assurance of only 608 deaths among adults for the year 1915. Nothing could be more misleading.

The two-century-old conviction that syphilis was responsible for a great many internal disorders (Morgagni, 1761, and Lancisi, 1728) did not really bear fruit until the seventh and eighth decades of the last century. Fournier started the ball rolling; but it was the discussion on Erb's paper, "Syphilis and Tabes," at the 1881 London Congress that roused the profession. To the distinguished Heidelberg clinician, still more to the great syphilographer, Fournier, and to that model physician in mind and method, William R. Gowers, we owe the demonstration of the important part played by syphilis in the etiology of the chronic diseases of the nervous system. I remember the discussion as if it were yesterday, and I have re-read it with no little astonishment. And yet as the actual demonstration of to-day was lacking the clearest eyes saw but through a glass darkly and we must sympathise with an opposition which was able to bring so large a body of negative evidence against the new view. The evening after the discussion an interesting incident happened at Dr. Bristowe's house. Bouchard, Erb, and one or two others talked over the subject. Bristowe, who was a waverer, emphasised the point that many physicians had locomotor ataxia who certainly had not had syphilis. Turning to me he said: "Now our mutual friend X has surely not had it—he would have told me!" I felt sorry to have to say that I had seen our mutual friend on the continent under treatment with secondary symptoms!

The improved technique by which the spirochæte is demonstrated in the tissues and the serum reactions have opened a new chapter in our knowledge of the prevalence of the disease. The profession has read it with amazement, the sanitary authorities with bewilderment, but best of all the public is actually reading the chapter in the open!

EXAMINATION OF REGISTRAR-GENERAL'S MORTALITY RETURNS.

Let us see now what the Registrar-General can tell us about the book-bills of the Cyprian. Germs show singular preferences for different parts of the body—the tubercle bacillus for the lungs and lymph glands, the *Plasmodium malariæ* for the blood, the lepra bacillus for the skin, and the *Spirochæta pallida* for the nervous system and the blood-vessels. Of the 562,000 deaths in 1915 about 58,000 were due to diseases of the nervous system. Two of these need not detain us. Locomotor ataxia and general paralysis of the insane *are* syphilis and account for 735 and 2263 deaths respectively. Now that is as much as we can say positively about the lists on pp. 146 and 148 of the Report, but let us take the other diseases in order.

A certain number of cases of meningitis are syphilitic, but they cannot be picked out from Class C—returned as "Other forms," numbering more than one-half of the total deaths from this disease. We may leave this out altogether. After locomotor ataxia comes "Other diseases of the spinal cord," 2846 deaths, a larger proportion of them in the fourth to the sixth decades. Any neurologist would say that a reasonable estimate would take at least one-half of these—say, 1500. By far the largest single cause is cerebral hæmorrhage—apoplexy—25,423, a majority of the deaths occurring after 50, beyond which age it is the privilege of any man to rupture a blood-vessel in his brain without suspicion. 3713 of these deaths were between the ages of 25 and 50, of which 3000 could be claimed as due to syphilis. "Softening of the brain" should long ago have gone into the limbo of unused terms with "rising of the lights," but there are 1472 returns under that caption; who could deny us 500 of these? The "Paralyses without specified cause," 2983 cases, is a hopeless section, but as more than two-thirds were hemiplegia we could be given at least 500. That a certain proportion of other forms of mental alienation, 1100 deaths, were cases of G.P.I. is very probable. Judging from the studies of Leonard Finlay[5] and of Fraser and Watson,[6] epilepsy, spastic diplegias, and mental deficiency are common results of congenital syphilis. The extraordinary amount of latent neuro-syphilis in the community is well brought out by the studies of Southard and his colleagues at the Boston Psychopathic Hospital. From epilepsy, infantile convulsions, and "other diseases of the nervous system," which mount up to about 15,000, we could claim a couple of thousand at least. This gives us a total from this section of about 10,000 deaths in which syphilis is a probable cause of death.

The spirochæte attacks the vascular system in preference to all other parts, and many of the deaths noted as apoplexy and meningitis, &c., are really from blood-vessel lesions. Aneurysm, the first important internal disease to be attributed to syphilis, and the aortitis on which it depends are usually spirochætal. Between the twenty-fifth and the fifty-fifth years the cases are always spirochætal; in the young they may be embolic and in the aged atheromatous. Of the 1141 deaths we could put down 1000 to syphilis. There is a terrible bill opposite organic disease of the heart, 56,000 deaths. About 17,000 of these are between the ages of 30 and 55, and a majority of these are in men. Unfortunately, valvular disease and the myocardial cases are not differentiated from the others, nor the aortic from the mitral. For reasons to be referred to later we shall be safe in taking one-third of the cases between 30 and 55—say, 5000 at least—and we may take an equal number from the 10,000 dead of diseases of the arteries, atheroma and aneurysm. A low estimate would put the cardio-vascular deaths due to syphilis at above 10,000.

It is unnecessary to bring in the comparatively small number contributed by other organs, the liver, lungs,

[4] Medical News, Feb. 26th, 1916.

[5] Glasgow Med. Jour., 1914.

[6] Journal of Mental Science, 1913.

larynx, kidneys. We have enough to put the grand total of the ravages of the *Spirochæta pallida* above 60,000, and to move syphilis from the tenth place in the Registrar-General's Report to which it belongs—*at the top, an easy first among the infections*. Many years ago in the "Life and Death of Mr. Badman," I came across Bunyan's phrase the "Captain of the Men of Death," which "caught on" in the literature. In his day it may have been true of consumption; it is so no longer; the headship in temperate climates belongs undoubtedly to syphilis.

POST-MORTEM EVIDENCE.

It was not without reason, some of you may now think, that I entreated my hearers' incredulity. There is a hazy uncertainty about these figures, I admit, but we shall find they are understated, not overstated. So impressed have clinicians and pathologists been with the absence of clear-cut evidence that in all parts of the world investigations are in progress dealing with the incidence of syphilis in ordinary hospital work. I cannot begin to quote all the papers, but I may refer to a few just to make you feel less incredulous about the character of my claims.

Dr. Warthin,[7] one of the best known of American pathologists, whose technique is only equalled by his patience and thoroughness, investigated the tissues in a series of consecutive post-mortems with the most scrupulous care to determine the existence of the spirochæte. One-third of the autopsies in adults showed its presence somewhere in the organs. Of these 41 cases only 11 were known to have had syphilis, 5 had active lesions in the nervous system, and 25 had shown no clinical changes suggestive of syphilis. In 36 there were syphilitic lesions in the heart (spirochætes demonstrated), 32 in the aorta, 31 in the testicles, 4 in the liver, and 6 in the adrenals. He concludes that interstitial myocarditis, aortitis, and fibrous orchitis form a triad distinctively spirochætal. The material from which this study was made represents an average intake of a hospital supplied largely from the country and from smaller towns of the State of Michigan. It would be interesting to repeat in one of the large London hospitals a similar study in 500 bodies, though the prolonged and tedious character of the work makes it almost impossible unless a special staff (after the war) could be appointed. It is the type of work that carries conviction, as the parasites are demonstrated in the lesions.

THE WASSERMANN REACTION.

The other method of inquiry does not carry the same weight. Not that the Wassermann reaction is not a satisfactory test of the presence of syphilis, but the technique is delicate and beset with difficulties that may vitiate the results. I will only refer, then, to studies made under the control of men I know, and with as great care as possible to perfection of the technique. C. H. Browning's paper[8] gives many details from English and Scotch sources.

My native country has a Conservation Commission which deals with everything from babies to beavers. I do not know the circumstances under which the Commission called for a report on the prevalence of venereal diseases, but they asked the members of the staff of the new Toronto General Hospital to undertake the work, and their report just issued (Jan. 17th, 1917) deals with all aspects of the problem. The point of interest here is that from 12 to 14 per cent. of patients admitted to the hospital show serological reactions characteristic of syphilis. In 60 per cent. of these persons the disease was not suspected. That the observations were made by Dr. Detweiler in the laboratory of Professor J. J. Mackenzie is a sufficient guarantee of the character of technique carried out.

The Brigham Hospital, Boston, is a new research hospital on the most advanced lines. Of 4000 patients examined by Walker and Haller,[9] 600 had been infected—15 per cent. Here again the latent cases far outnumber the active. In Baltimore Dr. George Walker, a well-known specialist, examined 1080 patients, 10 per cent. of whom gave the reaction. Of 327 prostitutes, 67 per cent. were infected.[10] Dr. John H. Musser, jun., reports that the examination of cases at the University Hospital, Philadelphia, gave 14 per cent. with the specific reactions for syphilis.

[7] American Journal of the Medical Sciences, 1916.
[8] Brit. Med. Jour., 1914, 1.
[9] Journal of American Medical Association, 1916, 1.
[10] Ibid., lxxvi., 1738.

I know there are those who look askance at the results of the Wassermann reaction which has not, and does not claim, mathematical accuracy, and it is a test on which much depends in the personal skill and honesty of the pathologist. These figures, from sources well known to me personally, may be trusted as far as one can such slippery articles. Modern research everywhere leads to three conclusions: (1) that there is an immense body of latent syphilis in the community; (2) that a very large number of persons have not been thoroughly treated; and (3) that to the enormous groups of cerebro-spinal and cardio-vascular deaths syphilis is an all-important contributor.

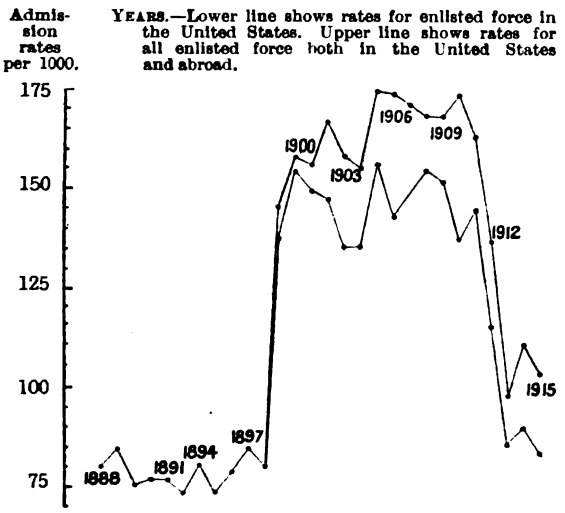
GROWTH OF CAMPAIGN AGAINST VENEREAL DISEASES.

The discovery of the spirochæte in 1905 gave an enormous impetus to the study of syphilis, while the improved treatment announced by Ehrlich in 1910 aroused hopes that at last—with the cause known and the cure assured—we had in our hands weapons for an effective fight. The public and its incorporated activities, the State, had persistently ignored its existence. Centuries of silence had made venereal disease taboo. Press and pulpit alike ignored the unsavoury subject. I doubt if the word syphilis occurs in the index of the *Times* until 1910, when a brief announcement of Ehrlich's discovery was made. Venereal diseases are rarely mentioned until the recent Commission, though, of course, a great deal of discussion took place upon the Contagious Diseases Acts History repeats itself. Imperial Rome is said to have been one huge brothel, in which sexual diseases were rife, though whether syphilis was one of them we do not know. The bibliophile Jacob (Paul Lecroix, who is also Pierre Dufour of the great work on prostitution) calls attention[11] to the hesitancy with which the Latin writers, medical and lay, refer to the *morbus indecens*, or, indeed, to any sexual disorder. To the rapid increase of venereal disease in them he attributes the appointment of State physicians by Nero.[12]

The beginning of the twentieth century saw us in a condition of hopeless apathy. Within a decade what a changed attitude in profession and public! You, Mr. President, started the former by the issue of your six-volume "System of Syphilis," which has proved such a useful armoury. Dr. Johnstone's report was an "eye-opener." The Royal Commission appointed in 1913 gave practical expression to a realisation of the importance of the problem by the public. Best of all, Lord Sydenham's report has not been sterile, as is so often the case with Royal Commissions. The rapidity with which it fertilised the House of Commons is unparalleled in the history of even that prolific lady. An outcome, too, of the work of the Commission was the founding in 1914 of the National Council for Combating Venereal Diseases, the primary function of which is educational. Under the wise guidance of Sir Thomas Barlow the Council has provided accurate and enlightened information to the public, and has

[11] Recherches Historiques sur les Maladies de Venus, Bruxelles, 1883.

[12] The question of the existence of syphilis in Graeco-Roman times has been re-opened with the proof of the presence of the disease in Europe before the discovery of America. I have asked Mr. Warde Fowler, the well-known authority in Roman social life, what he thinks of the bibliophile Jacob's statement. His reply is worth quoting:—"In my judgment the question depends on the evidence of Celsus entirely; all the rest which Jacob adduces is vague and indirect, and apt to give way when you probe it. For example, he makes a great point of slave doctors kept in big establishments, who would keep unpleasant diseases secret, and so on. I have looked up the evidence about these, and there is nothing more in it than that in a few very big establishments it was convenient to have a doctor on the spot, as in a big ship. The economy of those big households or farms was self-sufficing, in this as in other ways. And it was far from universal even in large farms, for Varro expressly says that farmers preferred to use the doctors of the neighbourhood. Again, he quotes St. Augustine for the Syrian luxury that came to Rome in the second century B.C., and jumps to the conclusion that all kinds of evil diseases came with it. That may have been so, but it does not come out of Augustine's words; and I am pretty sure that if Augustine had wanted to say so, he would have said it without any scruple. But, on the other hand, supposing that the passage quoted from Celsus distinctly points to syphilis or something like it, the fact that there is no mention of such things in Roman literature would not be enough to damage Celsus's evidence. What survives of Roman literature is mostly clean and in good tone, and one would not expect to find any such allusion in it. The absence of any allusion in certain poems of Catullus, and in the great passage about love at the end of the fourth book of Lucretius, might suggest that one shou'd be careful about interpreting Celsus, but would by no means be decisive. (I have just been over the Lucretius passage, and can find no trace of allusion to a morbus; and L. was very plain-spoken in such matters.) So I think that you must go by Celsus alone. Apart from him I should say there is no evidence of any weight, positive or negative." The difficulty with Celsus is a matter of interpretation. The lesions described are not necessarily sexual.



been a rallying centre for the various professional bodies interested in the subject. The work of the Eugenic Education Society under Major Darwin has been most helpful.

The outset of the great war has stimulated, not retarded, the plan of campaign. Since that memorable scene which shook the gods in Olympus with inextinguishable laughter Venus and Mars have been inseparable. War means an enormous increase in the number of infections. The last quoted figures for the British Army at home are (Hansard, April 23rd): 71,000 cases of gonorrhœa, 21,000 cases of syphilis, and 6000 cases of soft chancre. In the Canadian Army to March 31st, 1917, there have been 18,335 cases of venereal disease—figures which have stirred public opinion in the Dominions to the boiling point.

LEGISLATIVE ACTION.

Stricter prophylaxis should reduce these figures. I have had from Colonel Bradley, U.S.A., and Major Lyster, U.S.A., now stationed in England, the full details of the methods now carried out so successfully in the United States Army.

The annexed chart speaks for itself:—

1888-98.—During this decade the Army was stationed throughout the United States principally at small posts. No compulsory physical inspection; no systematic propaganda to reduce venereal disease. The rates represent practically those patients unable to do duty. Cases not treated or those doing duty were usually not recorded.
1898.—Spanish War. Militia called into service.
1898-99.—Great change in Army; marked expansion. Old soldiers disappear; volunteers come in. Young recruits sent to Cuba, Porto Rico, Philippines.
1899-1901.—Philippine Insurrection. Troops in Cuba, Porto Rico, China.
1901-09.—High rates prevail in United States and abroad.
1909-11.—Principles of preventive medicine applied; prophylaxis urged.
1911.—Syphilis increases. Wassermann test used in diagnosis.
1912.—Systematic measures. Fortnightly physical inspections and prophylaxis enforced by G.O., May 31st. Pay stopped, G.O. 31.
1914-15.—Concentration on Mexican border.

Various stimuli, public and private, have had at last the desired effect. The Government felt that opinion in the country was strong enough to act on the advice of the Commission and hand over the venereal problem to the public health authorities represented by the Local Government Board. The most sensible single bit of evidence given to the Commission was expressed by the Hon. Miss Brodrick, a trained nurse, that we should deal with the disease "as if it were small-pox or scarlet fever, simply as a disease quite apart from the moral side." This is what the Government has done. Recognising the existence of the disease as a great menace to public health, legislation has been enacted to fight the enemy on a settled plan at many centres under the control of the Local Government Board. It is a new departure to deal with an individual disease in this way.

What a change a single word may effect! Tuberculosis, the white plague, is really a more hopeful disease to fight than syphilis. Though it has the same strong allies, poverty and drink, there is absent the complicating problem of prostitution. The word "may" instead of "shall" in the Tuberculosis Act gave us an ineffective guerilla warfare of local bodies for a Kitchener and a general staff. The Government made no mistake this time—*shall* is the word, and all over the country the clinics are in course of formation. Nurtured upon the Reports of the Local Government Board, I dwelt with a purpose on the successful campaign which it had waged against typhoid fever. In that great warfare Sir John Simon was chief of staff, and the battle was won by able lieutenants who directed the actual fighting in various parts of the country. Read the story in his writings, and you will wonder how it ever could have been accomplished, against the opposition of Dogberrys inside and outside the House. Had the country listened to Sir John Simon half a century ago, when he advocated the "urgent need of control of the public health by a responsible Minister of State," our arrears in infant mortality and housing would not now be so heavy. Still, let us be grateful to him and to his successors for all the good work that has been done.

ESTABLISHMENT OF VENEREAL CLINICS.

No more hopeful legislation has ever been enacted than the establishment of these venereal clinics, with which the country will be equipped, though not fully, for the battle. But let the people and their representatives realise that they are dealing with the subtlest foe of humanity and the greatest sanitary problem which confronts civilisation. A general staff, controlling the campaign, will work from the Local Government Board (or before long, let us hope, from a Ministry of Health[13]) with laboratory, statistical, and social service departments, a publicity bureau and a library. The centres will be units working with a single object, and the doctors, nurses, and social workers will be members of a great national army.

Already the Commission—for it is its work—has done what the profession has not been able to do in these long years—opened the doors of the general hospitals to these victims. The governors and trustees have lined up at last with the good Samaritan. There are many institutions in which an up-to-date scientific clinic with laboratories will be a great boon. The profession welcomes the scheme from the educational side, as there will be within easy reach opportunities for the study of all aspects of both disorders, and from the practical side they will be able to bring their patients freely for special treatment, for special consultation, and for the laboratory tests which are so essential. There will, I hope, be at each centre lectures and demonstrations as have been organised in Liverpool. A sympathetic and loyal feeling on the part of the practitioners in each district is really essential to the success of the work.

Between the clinical and the laboratory side there will be enough at each clinic to occupy a large part of the time of a male and female doctor, who will, I trust, become the skilled advisers of the profession and of the public in each district. It should be our business to make these positions sufficiently attractive to catch the very best, and I am sure the hospital authorities will welcome them warmly as members on the staff. In large cities they might well be whole-time positions, though I should prefer to allow their colleagues and the public to have the benefit of their ever-increasing experience. A great missionary field will be opened for women doctors, who should do the work among their own sex at the clinics.

EDUCATION OF THE PUBLIC.

Nowadays, in the hospitals the individual is studied and cared for, not solely his or her disease. Social workers of the right sort with the right spirit, the helpful sympathetic spirit which—

> "Gently scans your brother man,
> Still gentler sister woman,"

will do much to make the clinics known and appreciated. The National Council could very well supervise this work which should be done by carefully selected volunteers. The clinic should be the centre in each district of an active educational propaganda which should be stimulated and planned by the general staff, and not left to the timid discretion of the local authorities. By meetings, literature, placards—in every legitimate way—a knowledge of the dangers of venereal disease should be distributed, and the importance of early and thorough treatment insisted upon. The public lavatories, the toilet-rooms of restaurants,

[13] The Waldorf Astor Report just issued, "The Health of the People: a New National Policy," should give a great stimulus to the unification of the many departments at present dealing with public health.

railway stations, hotels, and factories should be utilised in a crusade against advertising venereal quacks. The stage should be used actively, and such a play as Brieux's "Damaged Goods," while strong meat for the *young*, enforces on young men the lesson of the terrible risks better than the chapters in *Proverbs* or than any number of leaflets.

In every possible way the sympathetic coöperation of the public is to be sought. Get people to realise that it is a great communicable disease two-thirds of the victims of which are innocent, and much will be done to break down the present barriers of ignorance and false sentiment. For any legislation to be successful the people must be prepared. The problem bristles with difficulties, but the primary duty is to gain the confidence of the public and respect their feelings so far as they are consistent with the welfare of the State.

UNQUALIFIED TREATMENT.—NOTIFICATION.—COMPULSORY TREATMENT.

We are committed, then, to a campaign of education, and an elaborate scheme of treatment. Two circumstances make it probable that these measures—and a good beginning, let us grant—will not suffice in themselves to reach the enemy.

So deep is the stigma associated with the disease that patients avoid hospitals—even their family doctors—preferring quacks and others who promise a speedy cure. Legislation is in progress to prevent unauthorised treatment of the disease. The active sympathy should be sought of the 5000 men calling themselves herbalists, referred to by Mr. Hayes Fisher in the House. (Hansard, April 23rd, 1917.) I am sure the profession has no wish to interfere seriously with a calling which ministers to a thirst for "simples" so Gargantuan. These men have families and could be interested in public health; many of them are good botanists and of above the average intelligence. They know that syphilis and gonorrhœa are quite beyond the reach of herbs, and that even guaiacum—the holy wood—no longer avails.

To be successful in any fight the primary essential is to know where your enemy is placed. The Commission did not feel able to recommend confidential notification, nor does the new Act enforce it. Perhaps they were wise and knew their business better than some of us who advocate it. Realising as fully as anyone the strong arguments against notification, the gravity of the situation outweighs with me all private considerations, and I feel sure that within a year we shall be ready for the change. It works well, we are told, in Scandinavian countries, and it will be interesting to have the results from those Australian dominions in which it has been introduced.

Another point really more serious is also associated with notification. Both syphilis and gonorrhœa require protracted treatment. It is the partially or badly treated cases that come to us 10 to 20 years later with aneurysm or nervous breakdown. The primary symptoms are often so slight that it is impossible to get patients to continue a course of medication lasting a year or even more. Here is where the clinics will be on trial, and we shall watch their experience anxiously. I see reports from a Boston hospital at which 28 per cent. of the patients did not return, and to a New York venereal clinic 29 per cent. of the syphilitics came but once. To be successful in this fight we must have control of the patients—the treatment must be compulsory. It is so in the Army, from which the men with syphilis and gonorrhœa are not to be allowed to return to private life until a reasonable guarantee is given in each case of cure. If the House of Commons in any way represents outside opinion the public is a long way from appreciating the appalling risks they run. Though on the street to-day, the spirochæte may be in your home to-morrow. The very reasonable proposals of Captain Guest, Mr. Rawlinson, and Sir H. Greenwood (Hansard, April 30th), that sanitary and curative measures should be adopted in the case of persons, men and women, convicted of certain definite offences, was met by cries of ruthlessness and Prussianism. The probation officers and workers of the London Diocesan Police-court Mission know what they are talking about when they urge compulsory detention and treatment. Practised with Mars, it is no sex inequality to do the same with Venus, but the Government is committed, for a time at least, to a policy of persuasion, feeling that notification and compulsory treatment are too far in advance of public opinion. Mr. John Burns (Hansard, April 30th) thinks that the Local Government Board has the power to deal with the question of notification. I doubt if it could enforce the treatment of syphilis any more than it does in the case of tuberculosis.

THE OUTLOOK.

To many the venereal situation looks dark and hopeless. It is not. For the first time in history the outlook is bright, despite the fact of an inevitable increase of cases during and after the war. Three things have happened to justify this hope.

The public is at least awake to the necessity of an educational campaign, in which the appalling dangers of the disease shall be brought home plainly. Other means than those heretofore must be brought to bear in a full and free enlightenment upon the subject. Such literature as Corbett-Smith's "Problem of the Nations" and the various publications of the National Council are having an enormous influence. That the preaching of chastity appears a ghastly failure, in the face of the record of 800,000 fresh cases annually in this Christian kingdom (Melville White's estimate), is no reason why the earnest appeal for personal purity should not take the first place in the educational campaign. Where the Apostles had to confess defeat their successors need not feel discouraged, and had they not laboured so hard for so long the percentage of the poxed in the community might have been doubled. The reproach is not upon Christianity but upon earthen vessels too frail to hold it. Venereal disease has been called a bi-sexual problem. Patrol beside St. Martin's Church at this hour and you would be inclined to deny it; but remember, for the aggressive harlotage that still disgraces our streets man is primarily responsible. The blame, but not always the burden, is upon him. The pity of it is that the strong offences' cross is borne, not always by the offender, how much soever he may sorrow, but by innocent women and children who form more than one-half of the victims.

That the State has at last intervened is another ground for hope. In the matter of health you may trust the people. Once get democracy to realise that it is badly diseased and it displays a Job-like regard for its skin. Has not Tammany, a very synonym for corruption, given New York City the most progressive, up-to-date system of sanitation in the world? You will have gathered, Mr. President, that I am a strong advocate of strong central control in these matters. My inspiration does not come from Hegel or his bastard modern disciples, but from the fountain-head, the great teacher who tried in vain to bring the Athenians back to "thoughts of order, to disinterestedness in their functions, to that self-concentration of soul in one's own part, that loyal concession of their proper parts to others on which such order depends."[14] Plato tells us "States are as the men are; they grow out of human characters." How chastened has been the strong Ionian element in British life! The war has brought to the individual a Dorian realisation of duty never before witnessed. All that a man hath—all that he holds dearest are drawn into a new ideal of service to the State. It will not be so hard after this schooling to accept an ever-increasing control of the disease by a Ministry of Health, with notification and compulsory treatment.

Most hopeful of all is the changed heart of the people. At last the sinner is to receive Christian treatment. Above the mantelpiece of his library hung what the founder of my old school, the Rev. W. A. Johnson (Trinity College School, near Toronto), used to call the Magna Charta of humanity. In the centre of the most dramatic scene in the Gospels stood the woman taken in adultery. About her thronged the Scribes and Pharisees, with eyes turned from her to the Christ, stooping as he wrote with his finger on the ground the watch-words of the New Dispensation—"He that is without sin among you, let him first cast a stone at her." I should like to see a copy of this picture in every one of the new clinics in testimony that we have at last reached the full meaning of the priceless message, "Neither do I condemn thee; go, sin no more."

Fighting in this spirit, the soldiers of our "New Model" will put up an irresistible barrage against the most formidable enemy of the race—an enemy entrenched behind the strongest of human passions, and the deepest of social prejudices.

A BLOOD CHANGE IN GAS POISONING.

BY JAMES MILLER, M.D. EDIN., F.R.C.P. EDIN.,
CAPTAIN, R.A.M.C. (T.); PATHOLOGIST, 2ND SCOTTISH GENERAL HOSPITAL.

IN conjunction with my colleague, Captain Harry Rainy, I published a note on a new sign in Gas Poisoning in THE LANCET of Jan. 6th, dealing with some fourteen cases of the condition admitted to No. 2 Scottish General Hospital during the month of September last. Since that date the investigation has been carried out in my laboratory upon cases in Craigleith Hospital and the auxiliary hospitals in the Edinburgh area.

TABLE I.—*General Survey of the Cases, Excluding the 14 Already Recorded.*

No.	Polymorphs.	Lymphocytes.	Mononuclears.	Eosinophils.	Mast.	Period between gassing and examination.	Immediate symptoms.	Symptoms at time of examination.
15	36·2	55·4	2·3	5·08	0·4	1 m.	Twice gassed, unconscious second time.	Vomiting, dyspepsia, pains in head.
16	75·7	21·7	1·2	1·2	—	2 ,,	Unconscious.	Cough, tightness in chest.
17	49·3	45·6	3·0	2·0	—	—	—	—
18	54·5	36·3	4·0	4·5	0·6	—	—	—
19	56·2	37·0	1·9	3·9	0·9	1 m.	Choking sensation.	No symptoms.
20	53·8	38·6	4·3	2·1	1·2	6 ,,	Slight case.	,, ,,
21	40·3	54·8	1·8	2·4	0·6	13 ,,	,, ,,	Gastric pain, vomiting, losing weight.
22	58·5	37·4	2·5	1·1	0·2	12 ,,	Lost power of legs, but did not go sick.	Shortness of breath.
23	57·5	35·2	6·7	0·3	—	17 ,,	Slight case.	Chronic otitis media, no present symptoms.
24	59·9	37·9	1·1	0·5	0·3	1 ,,	Could not eat food for several days; stretcher case.	No symptoms. Suffering from scabies; discharged fit.
25	47·2	48·3	1·6	2·4	0·2	3 ,,	Became unconscious 4-5 hrs. after attack.	Languid, breathless, has sick spells.
26	32·1	63·7	2·8	0·9	0·3	3 ,,	Became unconscious in 1½ hrs. after attack.	Headache, cough, breathlessness.
27	50·5	43·2	2·5	3·5	0·5	12 ,,	Unconscious 4 days.	Has frequent attacks like pneumonia which last 3-4 days and subside.
28	52·4	43·7	1·5	1·8	0·3	3 ,,	Cough and breathlessness.	Cough persists, but is much improved.
29	70·3	26·9	1·1	1·4	—	3 ,,	Cough, vomiting, and unconscious.	Dyspnœa and pain in chest.
30	53·2	41·9	0·9	3·8	—	2 ,,	,, ,,	,, ,,
31	49·4	49·4	0·9	0·3	—	3 ,,	Slight cough, copious catarrh.	Cough and spit.
32	56·4	41·7	0·4	1·3	—	3 ,,	Vomiting, severe headache.	Severe headache.
33	35·5	56·2	3·0	5·0	0·5	1 ,,	Vomited; stretcher case.	Dyspnœa and pain in chest.
34	47·0	49·0	1·08	1·9	0·2	3 ,,	,, ,,	,, ,,
35	50·4	44·6	1·7	3·2	—	12 ,,	No symptoms.	No symptoms.
36	68·0	30·0	2·0	—	—	2 ,,	Vomited.	Tight feeling in chest.
37	37·8	54·8	2·6	3·5	1·1	12 ,,	Cough and vomiting.	Wheezing and cough
38	56·3	39·3	1·7	2·7	—	4 ,,	Not unconscious; vomiting not severe.	Bronchitis.
39	44·0	54·3	0·3	1·3	—	1½ ,,	Unconscious 4 hours; very severe case.	Breathlessness; tightness in chest; giddiness.
40	66·7	35·3	2·0	2·0	—	11 ,,	Unconscious 2 hours; back to duty in 6 days.	Complains of shortness of breath.
41	50·0	45·0	3·0	2·0	—	6 ,,	Did not feel much at time. A few days after, cough and breathlessness	Bronchitis.
42	59·4	34·9	2·9	1·8	1·0	20 y.	In bed with bronchitis for 5 weeks. Indigestion and bronchitis for 6 months thereafter.	None, but liable to bronchitis.
43	56·6	35·2	6·7	1·5	—	15 ,,	Pain, choking sensation, bronchitis lasting 3 weeks.	Almost complete loss of sense of smell.
44	47·7	47·5	4·0	0·4	0·4	2 m.	Slight.	Breathlessness and cough.

M, months; Y, years.

I gladly take this opportunity of thanking Major David Wallace, C.M.G., Red Cross Commissioner for the district, Dr. Graham Brown, and Miss C. M. C. MacNeil, M.B., of Seafield Military Hospital, Leith, and my colleagues in No. 2 Scottish General Hospital, for facilities in the work, and for notes of cases. I would specially mention Captain D. J. Glen, who has been of great assistance in finding out cases as they came into hospital. For the laborious work of making the blood counts I have to thank my assistants, Miss Jean McLean, M.D., and Mr. Malcolm Smith. The differential counts have in every instance been made upon at least 300 leucocytes, and they have been controlled by several observers and by repeated examination.

Investigation of Blood Changes.

The further investigation of the matter has merely confirmed the preliminary work as regards the main thesis, while modifying the conclusions in one or two respects.

Table I. gives a general survey of the cases, excluding the original 14, with differential count, period elapsed since gassing, the immediate symptoms, and the symptoms at the time of examination. The statement in the original note that this change takes some time to develop, probably three to four months, has to be modified to this extent, that in severe cases the sign appears within a month or six weeks of the gassing, possibly sooner. Cases 33 and 39 show this to be the case. Our original statement was based upon Case 16, which eventually proved to be a much milder case of gassing than the statement of the man led us to believe, the man having since returned to duty.

In order to ascertain whether the relative lymphocytosis was due to an actual increase in the number of lymphocytes or to a diminution in the polymorphonuclear leucocytes, Table II. has been drawn.

TABLE II.

No.	—	Leuc. per c.mm.	Percentage. P.M.	Percentage. L.	Total. P.M.	Total. L.
	Normal Minimum.	5,500	70	20	3,850	1,100
	Normal Average.	7,000			4,900	1,400
	Normal Maximum.	9,000			6,300	1,800
1	Severe case.	5,000	50	40	3,500	2,930
3	Persistent symptoms.	5,968	47	44	2,820	2,676
4	,, ,,	6,570	33	60	2,168	3,942
6	,, ,,	6,500	51	45	3,315	2,925
7	Slight case.	7,812	58	35	4,530	2,734
9	Severe case.	6,562	39	51	2,593	3,360
10	Very slight case.	8,124	62	30	5,036	2,437
11	,, ,,	7,184	72	23	5,047	1,638
16	Severe case.	9,686	75	21	7,264	2,034
12	,, ,,	5,000	35	58	1,750	2,900
13	Severe case (1st examination).	8,122	47	47	3,816	3,816
39	Severe case.	11,562	50	46	5,781	5,300
15	Severe case (2nd examination).	17,000	37	58	6,401	10,034
13	,, ,, ,,	15,000	44	46	6,600	6,900

Table II. gives a series of cases taken at random in which a leucocyte count was made in addition to the differential count. From the two data—number of leucocytes per c.mm. and percentage of the two main types found—the actual number of lymphocytes and polymorphonuclear leucocytes has been given in figures. The first lines of the table give the average in normal cases at what may be taken as the physiological limits and the mean.[1] This table shows that in all cases in which the sign is marked—i.e., in the cases in Table II., with the exception of Nos. 10, 11, and 16, which were slight, there is an absolute increase in the number of lymphocytes. In certain cases there is some diminution in the number of polymorphonuclear leucocytes, which tends to accentuate the sign, but the lymphocytosis is, nevertheless, an absolute one. Moreover, in Cases 13 and 15, which show a fairly well-marked leucocytosis, there is still a lymphocytosis. These cases are given in detail below.

Table III. classifies the cases according to the degree of lymphocytosis.

It will be seen that all with a count of 50 per cent. or more of lymphocytes are severe cases, with the exception of No. 21, which was a slight case of gassing, but the symptoms have persisted to the present time—i.e., 13 months after the gassing. Of those with a lymphocyte count of 40 per cent. or over, all, with the exception of two, Nos. 31 and 35, are severe cases or cases with persistent symptoms. Too much stress cannot, of course, be laid on these percentages, but we have found that they are wonderfully constant on repeated examination and by different observers.

[1] Gulland and Goodall: The Blood, second edition, p. 78.

TABLE III.—*Cases with High Lymphocyte Count.*

(A.) *Count of over 50 per cent.*

No.	Lympho-cytes.	Interval in months.	Symptoms.
8	56·3	12	Severe case, unconscious 4 hours.
9	51·7	11	Fairly severe, dazed, cough still.
12	58·2	17	Severe case, unconscious.
21	54·8	13	Slight persistent gastric symptoms.
37	54·8	12	Fairly severe, cough and wheezing still.
4	60·0	5	Severe case, symptoms still.
15	55·4	1	Severe case, persistent symptoms.
26	63·7	3	Severe case, unconscious.
33	56·2	1	Severe case, vomiting.
39	54·3	1½	Severe case, unconscious.

(B.) *Count of over 40 per cent.*

3	44·6	12	Marked case, eye symptoms still.
6	45·2	12	Fairly severe, eye symptoms still.
13	47·6	12	Severe case, unconscious.
27	43·2	12	Severe case, still symptoms.
35	44·6	12	Slight case, no present symptoms.
1	40·8	3	Severe case.
2	40·0	3	Marked symptoms.
14	40·0	(2)	Partly unconscious, symptoms still.
25	48·3	3	Unconscious.
28	43·7	3	Slight case.
30	41 9	2	Unconscious.
31	49·4	3	Slight.
32	41·7	3	Vomited, headaches.
34	49·0	3	Vomited, stretcher case.
41	45·0	6	Fairly severe case, symptoms still.
44	47·5	2	Slight case, persistent symptoms.

A classification of the cases according to the period which has elapsed since the gassing (Table IV.) does not yield any very definite information beyond the fact that the sign is a wonderfully persistent one, and has not disappeared in any instance in my experience.

In this relation I was fortunate in being able to examine the blood of two schoolmasters (Cases 42 and 43) who had been gassed with chlorine, the one 15 and the other 20 years previously. Both suffered severely at the time and symptoms persisted, in the one for some weeks and in the other for many months. The counts in each instance give a slight relative increase of lymphocytes, but they are probably not outside the limits of error.

TABLE IV.

9 and over 9 months.

No.	Months elapsed.	Symptoms.	P.M.	Lymph.
3	12	Marked case with eye symptoms.	47·6	44·6
5	12	Slight case.	59·2	33·4
6	12	Fairly severe with eye symptoms.	51·1	45·2
8	12	Severe, unconscious for 4 hours.	37·5	56 3
9	11	Fairly severe, dazed, cough still.	39·9	51·7
10	12	Slight case, no present symptoms.	62·3	30·2
11	9	" " " "	72·1	23·4
12	17	Severe case, unconscious.	35·3	58·2
13	12	Severe case, unconscious, but no symptoms now.	47·9	47·6
21	13	Slight case.	40·3	54·8
22	12	Did not go sick, still breathless.	58·5	37·4
23	17	Slight case, no present symptoms.	57·5	35·2
27	12	Severe case, still complains.	50·5	43·2
35	12	Slight case, no present symptoms.	50·4	44·6
37	12	Fairly severe, cough and wheezing still.	37·8	54·8
40	11	Fairly severe, symptoms still present.	66·7	35·3
		6 or under 6 months.		
1	3	Nausea, severe gassing.	50·2	40·8
2	3	Marked symptoms, symptoms still.	53·1	40·0
4	5	Severe, symptoms still.	33·5	60·0
7	2	Very slight case.	58·5	35·0
14	2	Half unconscious, slight symptoms still.	50·0	40·0
15	1	Twice gassed, unconscious, symptoms still.	36·2	55·4
16	2	Unconscious.	75·7	21·7
19	1	Choking sensation.	56·2	37·0
20	6	Slight case.	53·8	38·6
24	1	Stretcher case.	59 9	37·9
25	3	Unconscious.	47·2	48·3
26	3	"	32·1	63·7
28	3	Slight cough, breathlessness.	52·4	43·7
29	3	Unconscious.	70·3	26·9
30	2	"	53·2	41·9
31	3	Slight case.	49·4	49·4
32	3	Vomiting and headache.	56·4	41·7
33	1	Vomiting, stretcher case.	35·5	56·2
34	3	Vomited, stretcher case.	47·0	49·0
36	2	Slight case.	68·0	30·0
38	4	Vomiting, persistent bronchitis.	56·3	39·3
39	1½	Severe case.	44·0	54·3
41	6	Fairly severe, persistent bronchitis.	50·0	45·0
44	2	Slight case, persistent bronchitis.	47·7	47·5

As regards the type of gassing (i.e., whether cloud or shell) it was not always possible to get a decided answer.

Of the cases in which a definite statement was obtained 16 were cases of cloud-gassing and 16 cases of shell-gassing. As regards the further question of the chemical nature of the gas nothing decided can be stated. Sometimes the men described the smell and first sensations produced by the gas, but usually, as might be imagined, their minds were not very clear on this point.

The type of gassing and the chemical nature of the gas do not, however, appear to make any difference as regards the blood change. Of the 10 cases in which the lymphocyte count is over 50 per cent. 4 were definitely cases of cloud-gas poisoning and 4 were cases of shell-gassing. In the other 2 the nature of the gassing was uncertain.

In 8 cases the statement was volunteered that the gas was of British origin. In 24 it was either certainly or probably German.

Classification: Cases with Counts Approximating to Normal.

On investigating the cases a little more closely they may be classified into groups. In the first place, a group the counts of which approximate more or less closely to the normal, which are, in other words, either normal or within the limits of error. Of these six—viz., Nos. 5, 10, 11, 19, 22, and 23—are definitely slight cases in which the gassing was a secondary consideration. Taking No. 22 as an example:—

No. 22.—Man gassed on Sept. 25th, 1915, through lifting his helmet for a couple of seconds only. He lost the power of his legs for some ten minutes, but did not vomit. He has always suffered from bronchitis and asthma, but has been worse since the gassing. He did not go sick until some time afterwards, but he has since been dismissed from the Army on account of his asthma. This is a case in which a condition previously present was aggravated by gassing, but clearly the actual gassing was not severe.

There is another series of cases in which counts approximately normal were obtained but in which the gassing was moderately severe. These require a rather more careful scrutiny. Such are Nos. 16, 24, 29, 36, 38, and 40.

No. 16.—Man gassed in July, 1916. His statement is that he was rendered unconscious, and he complained when admitted to hospital of cough and tightness in the chest. He was sent to a convalescent home soon after, where he was punished for breaking bounds, and he has since rejoined his unit and has received promotion. It is clear that he cannot have been a severe case of gas poisoning.

No. 24.—Man gassed with cloud gas in August, 1916, through not having his helmet on. He was not rendered unconscious, but had to be carried back on a stretcher. He could not eat food for several days. He suffered from cough. His symptoms had practically disappeared before admission to hospital. A note from the medical officer of the convalescent home to which he was sent states that he had neither gastric nor pulmonary symptoms when discharged. He has since rejoined his unit.

No. 29.—Man gassed with shell gas at end of July, 1916. He had no helmet on and suffered from vomiting and breathlessness at once. These symptoms continued. Fourteen hours later he became unconscious and remained so all day. He continued to suffer from cough with expectoration, and when admitted to hospital complained of breathlessness on exertion and pain in chest. No heart lesion found on auscultation. Although showing an almost normal blood count on Oct. 25th, the count a month later was as follows: Polymorphs, 58·7; lymphocytes, 39·3. The man was suffering from psoriasis. This man volunteered the statement that the gas smelt like ammonia.

No. 38.—Man gassed at same time as No. 29. He states that the gas which was shell had a sickly sweet odour. He vomited immediately, but had no cough or breathlessness and did not become unconscious. He was able to put on his helmet. He continued in action all night and felt better in the morning. His age is 41, and he has suffered from cough for many years. His present attack of bronchitis began two months after the gassing. He is evidently a case of chronic bronchitis of long duration.

No. 40.—Man gassed in December, 1915. He is uncertain whether it was shell or cloud gas, but it had a "pleasant smell." It made his eyes water and caused severe coughing. He felt "intoxicated" and became unconscious, remaining in this condition for about two hours. He vomited freely in the dressing station. He returned to duty after six days. He has always been subject to asthma and bronchitis, but since being gassed he has been very short-winded. His medical officer has no doubt that he exaggerated the story of the gassing, as he makes the most of all his ailments. His present attack of bronchitis does not appear to have been connected with the gassing. A second examination of blood, a month after the first, resulted as follows: Polymorphs, 57·5; lymphocytes, 33·5.

No. 36.—Man gassed with shell gas on August 21st, 1916. He vomited, but did not become unconscious. He complains of having a large amount of spit every morning; also of tight feeling in chest and pain in left side. He looks very well and nothing can be made out on examination. The film, which was sent from a distance, was bad. No great reliance can, therefore, be placed on the result, but as the man has returned to duty the case is obviously a slight one. The medical officer of the convalescent home regarded the man as making the most of his condition.

It will be seen that of the above-mentioned cases three are much less-marked cases of gas poisoning than the story of the patient would indicate, all having returned to duty within three months of the gassing. Other two are cases of chronic bronchitis which happened to be gassed, but a considerable interval elapsed between the gassing and "going sick." No. 29, the only remaining one of the series, is

apparently a clear case of pretty severe gas poisoning without marked blood change. A complication in this case, however, is a skin condition—psoriasis.

Grouping of Cases according to Chief Symptoms.

The remaining cases may be classified into groups according to the nature of the chief symptoms. The larger proportion show at some period more or less marked symptoms associated with the respiratory passages. In another series of cases the symptoms are mainly gastric. Not infrequently both types are to be met with together. Still another series is those in which nervous symptoms predominate.

In a small group of two cases, Nos. 3 and 6, gassed at the same time (September, 1915, British gas) the chief symptom was obstinate conjunctivitis. This was associated with tremors. It is possible that the nature of the gas has something to do with the peculiarity of the symptoms. It is a striking evidence of the profound effect which gassing has upon the tissues of the body that a year after the gassing the conjunctiva should exhibit such marked inflammatory change.

Nervous phenomena are exhibited by a large number of cases sometimes in the form of what may be called neurasthenia, as in Nos. 15 and 27. Headache is severe and persistent in some—e.g., Nos. 15 and 32. Tremors were present in Cases 3, 4, and 6.

Gastric symptoms are among the most obstinate in some cases. Two of these, Nos. 13 and 15, are worth recording as they are associated with a high leucocyte count.

No. 13.—Gassed (British) in September, 1915. He lost consciousness some hours afterwards, and remained unconscious for four days. For several days afterwards he suffered from intense nausea and vomiting, and these persist in some degree up to the present time. He was sent home, and after a month returned to the Front, and remained there from November, 1915, till July, 1916. He remained fairly well until May, when he began to suffer from pains, particularly in the shoulder and chest, like a knife going through him. He was again sent home, and has been twice in Craigleith Hospital, with intervals at convalescent homes. He has constant nausea and disinclination for food and occasionally vomits. The pains in the chest and limbs also persist to the present time. His blood shows a persistent moderate leucocytosis (15,000). His differential count on last examination was: polymorphs 44, lymphocytes 46. There is thus an absolute increase in the polymorphs as well as in the lymphocytes, although it is more marked in the case of the lymphocytes. (See Table II.)

No. 15 is a very similar case who was gassed on two separate occasions—once (on July 30th, 1916) slightly, owing to sleeping through a gas attack in his dug-out; on another occasion (August 3rd) while trying to extricate an officer from his dug-out after the explosion of a shell. On the latter occasion he was rendered unconscious. His case is complicated by neurasthenia following shell shock. He suffers from persistent pains in the head and dyspepsia with frequent vomiting. His blood shows a moderate leucocytosis, 17,000. His differential count on the first occasion was: polymorphs 36·2, lymphocytes 55·4; on the second occasion, three months later, 37·3 and 58·3 respectively. The man is still in hospital and shows little sign of improvement.

The question arises as to what the leucocytosis is due to in these cases. Gastritis is undoubtedly the most prominent symptom, and it is reasonable to suppose that subacute inflammation of the gastric mucous membrane might account for it. The interesting point is that the lymphocytes are more markedly stimulated than the polymorphs.

Cases with respiratory symptoms.—The cases with marked and persistent respiratory symptoms are most numerous. The common complaints are pain in the chest, cough, and breathlessness. Such cases are Nos. 9, 25, 26, 31, 33, 37, 39, and 41.

No. 9.—Gassed (British) October, 1915. He was exposed for 20 minutes, but only complained of feeling dazed. He suffered from cough for three months, and in September, 1916, complained chiefly of breathlessness. On auscultation crepitations could be heard in both lungs. His was the case which first drew attention to the blood alteration. His count, confirmed on several occasions, was: polymorphs 39 per cent., lymphocytes 51 per cent. His leucocyte count was 6562 per c.mm.

No. 31.—Gassed on July 25th, 1916 (shell). He was partly buried by the explosion and stunned. He had breathlessness from the first, also vomiting. He was conscious at the time of a sweet, rather pleasant odour. At the time of examination (Oct. 20th) he had a slight cough and somewhat copious catarrhal expectoration. He had a scorbutic skin condition. The percentage of polymorphs and lymphocytes was the same—viz., 49·4.

No. 37.—Gassed on Sept. 25th, 1915 (British, burst cylinder). He was rendered unconscious by the shell which burst the cylinder, so that he had a good dose of the gas. When he recovered consciousness he started coughing and vomiting. He complains (Oct. 16th, 1916) of pain in the right side of chest. He is troubled with wheezing and coughing. His medical man, not being able to make out much in the way of physical signs, regards the man as a humbug. His count is: polymorphs 37·8 per cent., lymphocytes 54·8 per cent.

No. 39.—Gassed on Oct. 15th, 1916 (shell). He noticed a sweetish odour which caught his breath. He was unconscious for four hours. Oxygen was administered for four days. His most prominent symptoms are breathlessness, pain and tightness in the chest, and giddiness. He complains also of impaired digestion. His count was: polymorphs 44 per cent., lymphocytes 54·3 per cent. His leucocytes numbered 11,562.

No. 41.—Gassed May, 1916 (shell). He did not feel much at the time. A few days afterwards he developed cough and breathlessness. He is still suffering from bronchitis. His count is: polymorphs 50 per cent., lymphocytes 45 per cent.

Type of Lymphocytosis.—Cause of Blood Change.

The type of leucocyte which is increased is the small lymphocyte with relatively large deeply staining nucleus and relatively little protoplasm. In a few cases there was a fair sprinkling of larger lymphocytes with a broader rim of protoplasm and a larger nucleus. No other type of blood cell appeared to be influenced in any constant fashion.

The last point which arises is the question of the cause of the blood change. A relative or absolute lymphocytosis is met with as an accompaniment of a large number of pathological conditions. Of the list mentioned in Gulland and Goodall only two—viz., chronic catarrh of the small intestine (relative lymphocytosis) and whooping-cough—seem to have any relation to conditions met with in gas poisoning. Undoubtedly gastric catarrh is a prominent symptom in a large proportion of these cases.

The blood change would appear to have no relation to the nature of the gas employed. Apparently, therefore, it is due to some change set up which is common to all types of gas poisoning. It may be that it is the chronic catarrh of respiratory or alimentary mucous membranes which explains it, but we are still in the early stages of our knowledge of the effects of gas poisoning on the body. They are undoubtedly very profound and persistent. No mention is made of any blood change in the official Memorandum on Gas Poisoning in Warfare, but that pamphlet deals only with the immediate effects of the various gases. We know, however, that catarrh of respiratory and gastric mucous membranes is present in the early stages and tends to persist. Lymphocytosis is met with in tuberculosis, syphilis, and other subacute and chronic infections. From analogy, therefore, one would judge that the chronic catarrh is a factor in the production of the change. In two cases with marked gastric symptoms there was a moderate leucocytosis with a persistent high lymphocyte count.

Recently I had the opportunity of examining the blood of an officer who was accidentally gassed in this country with chlorine. The accident happened on Jan. 24th, 1917, and the blood was examined on the 27th. The red cells numbered 5½ millions, the hæmoglobin was 98 per cent., and the white cells were 5,900 per c.mm. Beyond a slight leucopenia, there was therefore no change. The differential count was normal: polymorphs 68·5, and lymphocytes 25·5.

Little can be gathered from the examination of a single case, but what evidence there is goes to show that the gassing results in a destruction of leucocytes, but that at such an early stage there is no stimulation of any one type of leucocyte. The case was a very slight one, the patient returning to duty within a week of the gassing.

Summary and Conclusions.

1. In cases of gas poisoning in which symptoms persist, there is an increase in the number of lymphocytes, relative and absolute, in the circulating blood. In slight cases this may not be beyond the normal limits or in excess of what may be met with from other causes. In any marked case, however, the change is sufficiently striking to be of some importance in cases where the medical officer is in doubt as to the reliance to be placed upon the statements of men complaining of having been gassed.

2. The blood change is elicited by a differential count of the leucocytes, and it may be taken that a count in which the percentage of lymphocytes approaches that of the polymorphonuclear leucocytes, indicates that the patient is still suffering from the effects of the gassing—i.e., provided there is no other complicating disease present which might produce a similar change. A slight relative lymphocytosis is not an uncommon finding in men from overseas or in anyone, so that no great reliance can be placed upon the sign unless it is marked—i.e., unless the percentage of lymphocytes approaches closely that of the polymorphonuclear cells.

3. The cell which is increased is the ordinary small lymphocyte of the blood. There may be in some cases a diminution in the number of polymorphonuclear leucocytes which will, of course, accentuate the sign, but the increase of lymphocytes is an absolute one. Moreover, it appears in cases with a high leucocyte count.

4. The change is one which develops early, probably within a month of the gassing, and continues for a long time; in cases with persistent symptoms for at least 18 months.

5. The change appears to be independent of the kind of gas, and it is shown by patients exhibiting many varieties of symptoms.

6. It is not clear what the change is due to, but from analogy with other conditions exhibiting a lymphocytosis it is probable that chronic inflammatory change in respiratory and gastric mucous membranes is at least a factor.

Note.—Since writing the above I have had a further series of cases gassed during the early months of 1917. The same blood change is shown in marked degree. One of the cases after three months gives the following differential count: polymorphs 29·5, lymphocytes 66·6, mononuclears 2·0, eosinophils 1·9. These cases have shown more marked nervous phenomena—viz., sleeplessness and night terrors.

Edinburgh.

TRENCH FEVER.

IS THIS CONDITION A SPIROCHÆTOSIS?

BY H. MORELAND McCREA, M.D. R.U.I.,
CONSULTING PHYSICIAN, CITY OF LONDON MILITARY HOSPITAL.

With a Note on the Technique of Wassermann Reaction by

W. E. CARNEGIE DICKSON, M.D., B.Sc., F.R.C.P. EDIN.,
DIRECTOR OF THE PATHOLOGICAL DEPARTMENT OF THE ROYAL HOSPITAL FOR CHEST DISEASES; PATHOLOGIST TO FULHAM MILITARY HOSPITAL; LATE LECTURER ON PATHOLOGICAL BACTERIOLOGY TO THE UNIVERSITY OF EDINBURGH.

A CONSIDERABLE number of articles have recently appeared in the leading medical journals of the different countries at war on the subject of trench fever, together with theories as to its origin. A certain number of workers have discovered a spirochæte in the blood, and suggest that it is the source of infection. Riemer[1] has gone a step further and has succeeded in growing spirochætes by anaerobic blood culture, but he is in doubt as to whether he has discovered the cause of the disease.

A considerable number of trench fever cases have passed through my hands in the medical wards of the City of London Military Hospital, and it has been my custom to classify them as acute and chronic.

Acute cases do not arrive in this country until the acute symptoms have passed off. The patients give a history of the, now well known, characteristic symptoms of this disease—namely, a fever of 5 to 8 days' duration, of sudden onset, with or without shivering and acute pains in the lower limbs, particularly in the shafts of the tibiæ. On admission to hospital on arrival from abroad they show practically no symptoms, and do not complain of pain. In some cases, after a few days, generally 6 to 10 days after the temperature falls to normal, a relapse occurs which lasts 2 to 3 days with a return of pain in the limbs. Recovery is rapid and the patient may, or may not, have a second relapse. Should there be a second relapse, it is generally after an interval of about a fortnight, and the severity of the attack is much less than that of the first. In this way the disease dies out.

I have not investigated the origin of this type. The condition is relieved, if not cured, by the administration of salicylates, and the stay of the patient in hospital is of comparatively short duration.

Chronic cases.—A totally different state of affairs obtains in the second class of cases—namely, the chronic type. The patient is admitted convalescing from a recent attack of trench fever diagnosed in some cases as such, in others as P.U.O., and in others as myalgia. The last two terms cover a multitude of diseases found in men on active service, but the cases referred to in this article are only those in which the patients give a history of an attack of fever with the characteristic symptoms of trench fever. On admission the one symptom is pain in the shafts of the tibiæ with extreme tenderness in these regions. There is no evident thickening of the bone or periosteum and no sign of any skin involvement. The temperature ranges about the normal line, but is never above 100° F. When first these cases were admitted it was found that no medicine would relieve the condition except morphine, and the pains were frequently so severe as to necessitate its use. Salicylates and iodides gave no relief.

The condition resembled a syphilitic infection of the periosteum so closely that the question arose as to whether the Wassermann reaction was likely to be present. This was tested by Dr. Carnegie Dickson. (See below.) In the vast majority of cases he found that the Wassermann reaction was positive. The cases did not give a high index, but always a figure high enough for the reaction to be considered as positive. The patients' histories were carefully investigated, but in only 4 out of 63 cases could any history of syphilis be obtained. Possibly more could have given a positive history of syphilis, as soldiers, for obvious reasons, do not readily admit having had this complaint.

Intravenous injection of galyl was administered on the lines laid down for syphilitic cases—that is, injections of galyl followed in three days' time by intra-muscular injections of grey oil, once a week for ten weeks. As a result of treatment the patient's general condition distinctly improved, but the pains did not disappear with that rapidity for which one could have hoped. Many cases had a decided increase of pain during the night following the intravenous injections, and then for several days were comparatively comfortable. The very severe cases did not show any permanent improvement and were finally boarded out of the Army. During the course of treatment two of these developed very severe posterior nerve root pains, similar to those occurring in syphilitic conditions. However, more than half of the cases returned to duty with the Army. This may seem a small percentage of recoveries, but it should be pointed out that all the cases treated in the above manner were of a very severe type and had resisted all other forms of treatment. It is important to note that after a few intravenous injections the Wassermann test reacted negatively.

There is not the time at present to work out minutely the details of these cases, but is not the above additional evidence in favour of the spirochætal origin of the disease? We know that a positive reaction is found in other spirochætal diseases as well as syphilis, as in yaws, for example. Granted a spirochæte has been cultured from the blood of these patients, and the blood of a certain type of cases—namely, the long-standing ones—gives a positive Wassermann reaction, the natural deduction is that the disease is a spirochætosis.

As regards the acute type of the disease, it would be well worth while investigating the reaction, but it is possible that these cases are of too short duration to give a reaction.

It is recognised that the matter requires much more scientific study, and it is hoped that the above short notes in a few cases—about 60—may lead those who have the opportunity to make further investigations on these lines.

Note of Technique of Wassermann Reaction, by W. E. CARNEGIE DICKSON.

The technique employed in testing the Wassermann reactions in the foregoing cases was that elaborated by Professor Robert Muir, of Glasgow, somewhat extended, a series of 12 tubes being used for each case. In these the constants were the antigen (alcoholic extract of human heart, previously standardised), 0·1 c.c. slowly emulsified in 0·6 c.c. normal saline, and 0·05 c.c. patient's heated serum. The variant was fresh guinea-pig's serum from 0·01 to 0·3 c.c., the minimum hæmolytic dose of complement being separately estimated with each set of tests, so that the reaction could be calculated and stated in numbers of hæmolytic doses of complement. The hæmolytic system consisted of 1 c.c. 3 per cent. washed sheep's corpuscles sensitised with five times the M.H.D. of rabbit's H.I.B.

These cases were tested with my other routine cases along with the sera of known negative and syphilitic controls. The patient's sera were also tested alone without antigen, and the complement-deviating capacity of the antigen itself was also tested on each occasion. Five M.H.D.'s of complement was the usual "syphilitic margin" in these reactions, a strong positive serum running to 15, 20, 30, or more M.H.D.'s, and a negative either not absorbing any excess or only perhaps a half to one M.H.D. of complement.

THE SURGICAL USES OF OZONE.

BY GEORGE STOKER, C.M.G., M.R.C.P. IREL., M.R.C.S.,
MAJOR, ROYAL ARMY MEDICAL CORPS.

IN THE LANCET of Oct. 21st, 1916, a tabulated statement was given of 20 cases treated by ozone at the Queen Alexandra Military Hospital. Further cases are now recorded in the accompanying table.

Instructions for using ozone.—1. The accumulator should not be let down below 3½ volts; if it is, the ozone (if any) produced will not be strong enough to produce satisfactory results. The accumulators should be tested daily with a voltmeter, *and should be recharged every second day.*

2. The coil should be examined daily to see if it is sparking properly and the binding screws of the "trembler" screwed up tight.

3. The production of ozone should be tested before each patient is treated. This is done by holding a piece of white blotting paper saturated with the test: Starch, 1·25 per cent.; pot. iod., 0·25 per cent.; water, 98·50 per cent.; before the nozzle of the ozone tube. A deep blue colour should be produced in two seconds.

4. After using the flexible tubes they should be carefully wiped and steeped in *boiling* water for two minutes and then placed in cold water till they are again required. Ozone should be passed through the tubes to cleanse them thoroughly inside.

5. Boiled water *only* should be used for dressing and cleansing the wounds, sinuses, &c. Solutions such as lysol, carbolic acid, saline, &c., destroy the ozone by offering a field for chemical action.

6. It is emphasised that ozone will disclose the presence of (*a*) dead bone; (*b*) foreign bodies; (*c*) septic deposits; and it is useless to suppose ozone can effect healing till these conditions have been dealt with by the surgeon. The sudden appearance of fœtid pus is indicative of the existence of one of these conditions, and ozone should be continued to purify the discharge before any surgical operative steps are taken.

7. The usual changes that take place in the discharges are as follows: (1) Increase of pus; (2) decrease and disappearance of pus, which (3) is replaced by clear serum, which (4) eventually becomes reddish in colour.

8. It is reasonable to allow one week of treatment for every month of previous duration without healing, before healing can be expected.

9. The length of time for which the ozone is to be used depends on the size of the surface to be treated. The maximum time is about 15 minutes.

Table of Further Cases of Wounds, Sinuses, and Cavities Treated by Ozone.

M, months; W, weeks; D, days; Ap, applications; U.T., still under treatment; N.R., no result; Dec. Tr., declined treatment; R, removed.

No.	Nature of disability.	Previous duration.	Duration of treatment.	Result.
21	Twice plated for fracture of femur. "Plate" acted as "foreign body."	—	—	N.R.
22	Wound on instep, bell-mouthed sinus extending from dorsum to sole foot, 3 in. deep.	8 m.	3 m.	Healed.
23	Sinus in stump 2 in. deep.	10 ,,	7 w.	,,
24	Abscess cavity 3 in. deep, opening 4 by 3 in.	10 ,,	3 m.	,,
25	Ulcer on front of leg, 1¼ in. long, 1 in. deep.	18 ,,	3 ,,	,,
26	X ray burn, ulcer 10 by 4 in.	12 ,,	—	—
27	Large surgical wound, 10 in. long, 2½ in. deep, with inner opening leading to cavity in bone 2½ in. deep.	15 ,,	3 m.	Healed.
28	Sinus on left side of lower jaw, 1½ in deep.	4 ,,	5 w.	,,
29	Sinus extending from horizontal ramus of lower jaw 4 in. long.	1 ,,	5 ,,	,,
30	Compound comminuted fracture of upper third of left femur, causing sinus 3 in. deep.	17 ,,	6 ,,	,,
31	Fracture of upper part of thigh, leaving sinus 2½ in. deep, opening into cavity in bone, ¾ by 1½ in.	13 ,,	3 ,,	,,
32	Large wound on right side of face, 3 by 4½ in. with deeper opening extending into mouth.	3 w.	1 m.	,,
33	Sinus and cavity in tibia 1½ in. deep.	10 m.	15 d.	,,
34	G.S.W. leaving sinus in front of thigh 2½ in. deep.	10 ,,	—	,,
35	Sinus from inner angle of stump. Sinus from middle of stump 2 in.	10 ,,	3 w.	,,
36	Sinus 3½ in. deep below point of shoulder.	14 m.	—	U.T.
37	Sinus passing through middle part of thigh penetrating femur.	14 ,,	3 w.	Healed.
38	Sinus at point of chin, 1½ in. deep.	1 ,,	8 d.	,,
39	G.S.W. L. thigh, operation for dead bone, leaving large surgical wound 4 by 4 in. One sinus in femur 1 in. in diameter, 1 sinus in soft tissues 1 in. in diameter, both 2 in. deep.	17 ,,	—	,,
40	Suppuration after enucleation of eye.	18 ,,	4 w.	,,
41	Sinus 3 in. long extending from outer angle of flap.	10 ,,	5 d.	,,
42	Suppuration of socket after enucleation of eye.	6 ,,	5 w.	,,
43	Sinus at inner aspect of stump 2 in. deep, running into a cavity 2 by 3 in.	23 ,,	12 ,,	,,
44	Compound comminuted fracture of forearm, incised wound with sinus leading down to ulna 1½ in. deep.	4 ,,	3 ,,	,,
45	Ulcer on left chin.	2 ,,	6 d.	,,
46	Surgical wound 10 by 4 in. for removing of plate from femur, with 2 sinuses.	1 y.	2 m.	,,
47	Suppuration in socket after removal of eye.	6 w.	4 d.	,,
48	Ulcer on cheek with actinomycosis.	4 m.	17 ,,	,,
49	G.S.W. detaching all structures from brim of pelvis, leaving large cavity 4½ in. deep, communicating with bladder.	16 m.	—	Conval.
50	G.S.W. r. leg, 3 sinuses 1½ in., ¾ and 1 in. in depth.	10 ,,	—	Healed.
51	Sinus in stump, 1½ in. deep.	11 ,,	12 d.	,,
52	Compound fracture of ulna, flexor tendons gangrenous, had to be cut away.	13 ,,	1 m.	,,
53	Suppurating cavity in groin, 1 by 2½ in.	2 ,,	1 m.	,,
54	Sinus in foot, 1½ in. deep.	2 ,,	9 d.	,,
55	Excision of elbow-joint, leaving sinus 1¼ in. deep.	12 ,,	—	,,
56	Sinus in stump 3½ in. deep.	23 ,,	9 d.	,,
57	Two sinuses in upper part of thigh, outer sinus 2½ in. deep, inner sinus 3½ in. deep.	12 ,,	—	,,
58	G.S.W. sinus inner side of arm, leading down to bone, 3½ in. deep.	2 y.	—	U.T.
59	G.S.W. r. arm, suppuration and sinus 1¼ in. deep.	14 m.	—	U.T.
60	Sinus in thigh 2½ in. deep.	9 ,,	6 w.	Healed.
61	Sinus in buttock 2½ in. deep, shell piece came away.	3 ,,	6 d.	,,
62	Sinus in left humerus 1 in. deep.	23 ,,	5 ,,	,,
63	Surface wound after operation, a bell-mouthed sinus through forearm.	12 ,,	24 ,,	,,
64	Wound from operation 1 by 3 in. and sinus down to humerus.	15 w.	6 w.	,,
65	Bell-mouthed sinus over left external malleolus.	13 m.	2 m.	,,
66	Empyema left side, profuse discharge of pus.	9 ,,	—	N.R.
67	Bell-mouthed sinus in forearm.	5 ,,	1 m.	Healed.
68	Deep furrow in tibia 1 by 3 in. leading down to cavity in bone.	22 ,,	—	U.T.
69	Suppuration in right lacrymal sac.	18 ,,	21 ap.	N.R.
70	G.S.W. penetrating wound through calf.	6 w.	17 d.	Healed.
71	Sinus and subcutaneous space right side of back of neck.	3 ,,	10 ap.	,,
72	Ulcer on external malleous (right).	7 m.	3 m.	,,
73	3 sinuses in left thigh.	14 w.	17 d.	2 out of 3 sinuses healed.
74	Empyema left side, profuse discharge, very fœtid. Cavity in lung.	2 m.	2 m.	Healed.
75	Two sinuses in right thigh: (1) 2½ in. deep; (2) 2 in deep.	2 y.	—	Dec. Tr.
76	Sinus through arm double bell-mouthed.	4 m.	—	N.R.
77	Sinus and cavity in lower jaw.	1 ,,	19 d.	Healed.
78	Sinus in stump 2½ in. deep.	5 ,,	—	R.
79	Sinus in os calcis (right) 1½ in. deep.	9 w.	9 d.	Healed.

Remarks.

Case 22.—Withdrawn from treatment for operation for 3 weeks.

Case 26.—Ulcer healed rapidly until half original size, when patient left hospital of own accord.

Case 31.—Ozone disclosed cavity in femur containing piece of shell ½ by ¼ in. which came out without operation.

Case 32.—Wound extremely unwholesome and fœtid but smell disappeared within 5 days of using ozone.

Case 36.—Ozone disclosed and X rays confirmed existence of several pieces of metal in and about sinus and on shoulder blade. Returned for operation.

Case 39.—Sinuses healed 1 month.

Case 41.—Examination showed streptococci before ozone. They completely disappeared after second application.

Case 44.—This case is awaiting plating of forearm.

Case 49.—Returned after operation Jan. 9th, operation Nov. 1st.

Case 50.—Ozone disclosed dead bone, which came away.

Case 55.—Transferred to Oxford at own request.

Case 58.—Returned after operation, Dec. 13th.

Case 59.—Returned after operation, Nov. 30th.

Case 67.—Transferred to Aldershot.

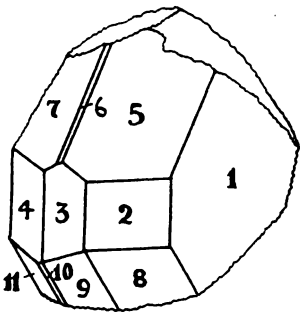
Case 69.—Returned for operation; lacrymal sac removed.

Case 72.—Returned for treatment after operation Dec. 18th.

Case 75.—Left of his own wish.

CRYSTALLO-CHEMICAL ANALYSIS AND ITS USE IN MEDICINE.

By T. V. BARKER,



UNIVERSITY LECTURER IN CHEMICAL CRYSTALLOGRAPHY AND FELLOW OF BRASENOSE COLLEGE, OXFORD.

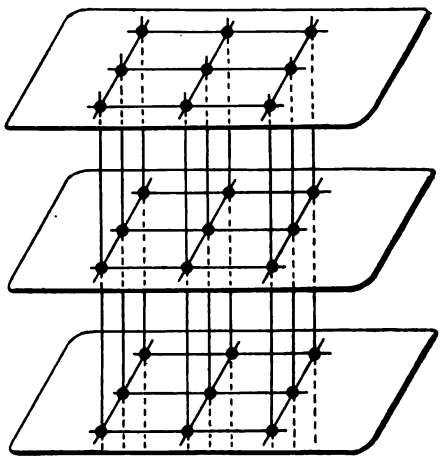
ON April 3rd I received a package from Dr. P. Govaerts (of the "Ambulance Océan," La Panne) containing a crystal of unknown composition and of intestinal origin, with the query: What is it? The crystal is shown in Fig. 1; it is seen to exhibit a moderately facetted development at the front end, the back portion being rounded. After an examination lasting 65 minutes it was possible to state that the crystal is "salol" (phenyl-salicylate). The correctness of this "diagnosis" was subsequently confirmed by a melting-point determination made on a tiny splinter weighing less than 0·0001 gramme (m.p. 43° C.), and by the specific optical properties of the resolidified fragment when examined under the polarising microscope.

Description of Crystallo-Chemical Analysis.

What was the method employed? A little reflection will negative the supposition that the substance had been subjected to chemical analysis. The crystal weighed (and still weighs) 0·229 gramme. The most expert chemist could scarcely hope to effect a complete analysis with this small amount of material. A little test-tubing might, it is true, have revealed the presence of a compound of salicylic acid; an organic combustion would have fixed the percentage of carbon and hydrogen, and so on. "Good luck," combined with a highly developed chemical instinct, might have been crowned with success. But suppose the crystal had been smaller; if its linear dimensions (9 × 7·5 × 4·5 mm.) had been one-tenth of what they happen to be, its weight would then have been of the order 0·0002 gramme. Any attempt at chemical analysis in such a case would be ridiculous. Identification, however, would have remained as sure as before, for the method adopted merely presupposes two conditions: first, that the crystal facets are smooth and light-reflecting; secondly, that the substance under investigation *happens* to have been previously examined by a competent crystallographer and its characteristic facial development put on record. Some 200,000 crystalline substances are known, of which about 10,000 have been properly investigated by the crystallographer; salol is one of the fortunate ten-thousand.

FIG. 1.

"Crystallo-chemical analysis"—the method of identifying well-crystallised products—we owe to the genius of Evgrav Stepanovich Fedorov, professor of crystallography in the School of Mines, Petrograd. Its immense possibilities are so obvious that the following brief description may be of interest to readers of THE LANCET.[1]



The specific nature of crystalline form was established a century ago. With the exception of a comparatively small number of substances which crystallise in the form of the cube or in forms having a simple relationship to the cube (crystals of the "cubic system"—common salt is an example), each definite chemical substance has its own *characteristic form*, whereby we mean that the plane faces are mutually inclined at specific angles. These angles can be measured in degrees and minutes by the help of the "goniometer." Measurement is especially rapid and exact with the latest form of instrument—the Fedorov theodolite goniometer. Thus, in salol—the angles between the pairs of faces numbered 1 and 5, 8 and 9 are respectively 60° 38′ and 13° 39′, and so on. The accurate measurement of a sufficient number of angles occupied half an hour. Twenty different angles were measured.

Now, suppose we assume that 20 angles have been measured on each of the 10,000 substances investigated by crystallographers, how are we going to sort out these 200,000 angles in the crystallographic literature in order to find a substance (if any) presenting that group of angular values which we have just obtained from the crystal under investigation? It is clear that any scheme of classification would be hopeless; there are too many variants to be classified, hampered as we are by a totally inadequate environment of space having merely three dimensions. If the number of variants (20) could be brought down to a respectable number, say three or five, the classification problem becomes feasible. Fedorov has devised a systematic and unambiguous method of reducing the number of variants. "Reducing" is not quite the right word; as we shall see later "integrating" is better.

Crystal Structure.

Crystal structure is a thing apart from all other structures; it is the very antithesis of "organised" structures associated with life. The latter macroscopically and microscopically reveal an intense differentiation of parts and functions. But the former reveals no such complexities, for all physical methods of exploration at our disposal (including, by the way, the recently discovered and very powerful X ray methods of research) converge to one conclusion—that down to molecular dimensions each part of a crystal is identical with, and similarly surrounded by, every other part. Let us draw on some sheets of paper two systems of equally spaced parallel lines so that they interlace at regularly recurring points or (alternatively let us potter about with some pieces of garden trellis-work) and arrange these sheets (or pieces of trellis) in parallel layers, taking care that successive sheets occupy similar positions—e.g., by drawing the upright system of lines included in Fig. 2. The points of intersection of the three sets of lines may be taken to represent the position of the structural particles (the lines are merely scaffolding—a figment of the imagination). Each crystalline substance has its characteristic array of particles, the chemical composition and constitution of the particle (molecule?) determining the exact arrangement. The arrangement typified by Fig. 2 is termed a "space-lattice." A glance at the figure is sufficient to show that it is nothing more or less than the spacial reduplication of a parallelepipedal cell, having particles at its corners. *Each crystal substance has a specific cell.*

FIG. 2.

Crystallisation is the union of free-to-move liquid or gaseous particles into a perfect, solid organisation. Crystal growth is a process of regular deposition from outside. Why such a growing crystal should take up a definite plane-polyhedral form, instead of forming rounded aggregates, is a question which invites speculation, but yields nothing profitable. In any case there is a simple mathematical relationship between the various faces on the most richly facetted crystal (the law of Haüy); there is an equally simple relationship between the external faces and the internal interlacing planes, or, in other words, between the faces and the form of the structural cell (the "law" or "principle" of Bravais). The nature of these laws need not be gone into. It will suffice to state that Fedorov deduces the

[1] For further information consult T. V. Barker, *Chemical News*, 1912, cvi., p. 199; Chemical Society's Annual Reports, 1913, x., p. 243; 1914, xi., p. 248; Times Russian Supplement, Feb. 26th, 1916, p. 11. I have in preparation a full treatise on the subject.

geometrical form of the cell from the facial development. All the faces are taken into account in this deduction. The process, then, is one of integration. The 20 (or more) angles on a crystal can now be rejected: *they are replaced by the angles of the cell.* These angles can be fairly easily classified in a book of three dimensions.

During the last ten years the whole of existing crystallographic literature has been brought under review by Fedorov and his work has been checked by his pupils, MM. Artemiev, Sokolov, and Barker. The chaotic mass of measurements and observations extending over a hundred years has been classified and incorporated into a one-volume "Index of the Crystal Kingdom," which will be published by the Petrograd Academy of Science. Proof-sheets of this monumental work are in my possession; without them the identification of salol could never have been effected.

Steps in the Process of Identification.

The steps involved in the identification of the salol crystal may now be briefly indicated. The measurement had occupied 30 minutes. The next five minutes were spent in plotting the results on a "stereographic map," which facilitates the study of the various angles (on this map the relative position of each crystal face is marked by angles of latitude and longitude originally read off from the goniometer). Twenty minutes were occupied in analysing the map, whereby three likely structural cells presented themselves as worthy of consideration. The following alternative lines of action were now possible: either to carry out certain graphical methods of calculation with a view to a final selection of that one of the three cells which satisfies most completely the Bravais principle, or to refer directly to the Index to see whether any of the three cells were included. The latter method was adopted as being easier. The third cell one had in view was, indeed, in the Index. On p. 691 there are no less than three substances having the cell in question—namely, salol, $HOC_6H_4CO_2C_6H_5$; potassium niobate, $K_{16}Nb_{14}O_{43}32H_2O$; and methyl di-isopropyl-sulphine hexachloroplatinate $[CH_3(C_3H_7)_2S]_2PtCl_6$.

We have evidently to probe the matter further. It need scarcely be stated that the intestinal origin of the crystal carried no weight in the decision as far as the writer is concerned. Integration of the crystal development had been extraordinarily effective; it had narrowed down the inquiry to three, crystallographically known, substances. But if there are three already known, why should there not be thirty unknown? In order to go further we have to abandon integration for differentiation; in other words, we have to go into details. The details are in the Index. On making a comparison of the list of faces developed on the three substances under consideration, there was a complete correspondence term for term with salol; not so with the remaining pair of substances. As a matter of fact, most crystalline substances enjoy little peculiarities. In salol the faces numbered 6, 9, 10 are not what one would expect to see developed from the standpoint of the Bravais principle: they are developed on all crystals grown in the laboratory; they were present on this crystal formed in the intestine. Again, the statement that there are three substances with identical cells is only true if we carry the angular measurements to an accuracy of ½° (30 minutes of arc), which is the limit of accuracy in graphical operations (unless they are carried out with such care as would involve a time better spent in exact trigonometrical calculations). The measurements of the crystal agree with those of "authentic" salol to a few minutes of arc. With regard to the more meticulous question whether the crystal is really some unknown (crystallographically, that is) substance, the reader may be assured that crystallographic experience is against this possibility. As has already been mentioned, confirmation of the truth of the purely crystallographic diagnosis was sought and obtained by a melting-point determination and by an examination of the optical properties, although such confirmation was hardly necessary.

The Future of Crystallography.

Although most precious results have frequently been obtained from the study of crystals (as witness, for example, Pasteur's capital discovery of the two forms of tartaric acid, the real basis of bio-chemistry), it must be admitted that the history of crystallography has not been a particularly happy one. Logically regarded, crystallography is a not unimportant branch of physical chemistry; it has, however, never been properly recognised by authorities, and consequently it has been doomed to a more or less precarious existence. The great development in recent years of the borderland between physics and chemistry must in any case gradually lead to a better appreciation of the "poetry of science," as crystallography has been so well termed; but the above account of one of its branches should make it clear that the science embraces a sphere of useful application in nearly all branches of knowledge, including those dealing with life-processes. How can this valuable adjunct be best turned to profit? It is obviously undesirable that a specialist in chemistry, physics, or medicine should attempt to become an expert in crystallography; if he is worth his salt his time is much better spent in exercising the arts towards which he has a personal inclination. He can, however, be of the utmost assistance to crystallography, and indirectly to his own subject, if he would only facilitate a more liberal recognition of its claims to be regarded as a worthy branch of inquiry. He can also be reasonably expected to coöperate in extending the usefulness of crystallo-chemical analysis. No substance can be identified unless it has been previously subjected to crystallographic investigation. It is evidently beyond the powers of the relatively small numbers of crystallographers to cope with substances as fast as they are turned out by synthetic chemists. Even if it were possible it would still be undesirable, inasmuch as the great majority of such compounds have their origin in a certain "superfluity of naughtiness" rather than in any real reasoning belief that the substance is likely to lead to the advancement of science and humanity; and the inclusion, in future editions of the Index, of a mass of *caput mortuum* would merely diminish its usefulness. It is therefore to be hoped that the chemist (in the wide sense of the term) will not take advantage of the ignorance of the enthusiastic crystallographer (who is, as a rule, only too willing to measure anything for the sheer love of æsthetics), but will confine his requests to such substances as are likely to have a direct influence on the development of science.

In conclusion, I wish to express my thanks to Sir William Osler and Professor W. H. Perkin for their genial interest.

Organic Chemical Laboratory and Mineralogical Department, University Museum, Oxford.

SPONTANEOUS RUPTURE OF THE SPLEEN.

WITH AN ACCOUNT OF A CASE DUE TO MALARIA AND ONE OF NECROTIC INFARCT WITH INTRAPERITONEAL HÆMORRHAGE SIMULATING SPONTANEOUS RUPTURE.

BY G. GREY TURNER, M.S. DURH., F.R.C.S. ENG.,
MAJOR, R.A.M.C. (T.F.).

AN experience of nine months' work in Mesopotamia has made me familiar with many complications of disease which may demand surgical interference. This has been especially so in the enteric infections and in those of the dysenteric group, but even in malaria the enlarged and softened spleen may give way, resulting in hæmorrhage into the peritoneal cavity, as pointed out in an annotation in THE LANCET of July 22nd, 1916. Although there were no symptoms in the first case to suggest surgical interference, it is easy to picture circumstances in which such interference might be necessary, as in the second case, which was, however, not strictly an example of spontaneous rupture. Incidentally, I should like to remark that both of the cases show the great importance of post-mortem examinations.

CASE 1.—*Spontaneous rupture of malarial spleen.*—Patient, seaman aged 35, an unusually big, strong man, admitted to British General Hospital at Basrah on June 17th, 1916. Ten days previously he had "reported sick" on account of pains in stomach, vomiting, and constipation, and had been treated with quinine for "fever." On admission he was a little anæmic and expression very anxious. Temperature 101·4° F., pulse 88, of very poor tension; tongue very much coated, and dry. Abdomen was flat, neither rigid nor tender; spleen easily felt below costal margin. Nothing abnormal discovered in chest. Malarial parasites found in blood; also mononuclear leucocytosis. On morning after admission temperature 102·4°, but no other change in condition; bowels had been well moved. By the evening he looked much worse, had vomited several times, and complained of difficulty in breathing, but there was nothing to suggest any abdominal development. On the 19th it was reported that during the night patient had become restless and delirious, and in early hours of morning had developed generalised convulsions, most marked in

arms and lower jaw, the teeth being constantly champed. Some cyanosis; pulse quick and feeble. Death occurred at 10 A.M. No response to quinine, either when given by the mouth or by intramuscular injection.

Post-mortem.—I made a necropsy five hours after death. Abdomen contained moderate amount of unclotted blood, fairly uniformly distributed over whole peritoneal cavity. In spleen pouch was a considerable amount of clot and a smaller quantity over right lobe of liver and in pelvis. The spleen itself was twice normal size, and on outer surface near upper pole were two small lacerations each about ¼ inch long and with pouting margins, as though produced by bursting of the structure. These punctiform ruptures were evidently the source of hæmorrhage, which was most abundant around spleen; no other cause could be found. There were no adhesions which might have been torn, thus giving rise to bleeding, and no signs of injury to overlying ribs or parietes such as might perhaps have been caused by patient falling out of bed, nor was there any evidence of embolism or thrombosis. The intestines did not show any of the lesions of typhoid or dysentery. Lungs congested, but no consolidation; heart and kidneys normal. The head was not examined.

In this case, so far as I was able to ascertain, there was no acute attack of abdominal pain, and though from the first the patient was obviously very ill, there was nothing to suggest any peritoneal lesion while the man was under my care.

Vomiting is quite common in malaria, and, I think, especially so in the type we met with in Basrah about that time. I certainly thought that he might be suffering from an enteric group infection, but that was more from a consideration of his general symptoms than from any local abdominal signs. I do not think that the accident of spleen rupture had much to do with the death of this patient, for his symptoms were exactly like many others in which a fatal malaria was of the cerebral type. Under ordinary circumstances spleen blood clots easily, and from my experience of hæmorrhage generally I was led to conclude that the blood coagulation-time is diminished under the climatic conditions prevailing during the hot weather in Mesopotamia. I believe that recovery without interference not infrequently occurs even in traumatic cases and would certainly have followed in this case had there been nothing else to account for death. I do not think that spontaneous rupture of the malarial spleen can be at all common, for though this disease was rife both at Basrah and Amarah beyond this case, in which it was proved, and one other in a Sepoy, in which it was suspected, the patient recovering, I have not come across another instance, nor have I heard of any in talking over the matter with my brother officers, though an enlarged and friable spleen was the commonest of the disclosures of the post-mortem room.

CASE 2.—*Enteric group infection with intraperitoneal hæmorrhage regarded as being due to spontaneous rupture of spleen and subsequently proved to be in association with infarction of that organ.*—Patient, aged 30, driver in R.F.A., admitted to British General Hospital at Amarah. I was asked to see him about 7.30 P.M., Sept. 6th, 1916, as a possible case of ruptured typhoid ulcer. The man had been very ill for five weeks with what was diagnosed as a fever of enteric group, and for previous two days temperature had been going up, attributed to a concomitant malaria. About noon of the day I saw him he first complained of abdominal pain and twice vomited, while his pulse became quick and feeble, but I could not elicit any history of a definite sudden onset. He had been given a dose of morphia, and as its effect passed off the pain recurred.

On subsequent inquiry I ascertained that this man was admitted to the hospital on August 12th with fever of 14 days' duration. He was very ill and was at once placed on "dangerous list." Temperature was of irregular type, as high as 102° F., and only occasionally touching normal. Pulse varied between 76 and 90; very poor in tension. Tongue dry and furred; bowels fairly regular. At that time spleen was not felt, but a little later its edge was detected two inches below costal margin. The blood, examined on several occasions, was always found negative for malaria; Widal test inconclusive. Patient continued in an unsatisfactory state and with irregular pyrexia, but little other change until Sept. 1st, when he complained of pain in left side of chest; patch of pneumonia found at left base. This did not appear to give him much additional distress, but temperature gradually rose, and on evening of Sept. 5th reached 103°, and on the 6th occurred the attack for which I operated.

When I first saw him the man looked exceedingly ill and was obviously in the later stages of some wasting disease. He was anæmic and slightly cyanosed and lay partly propped up in bed sweating profusely, with feeble pulse of 132 and temperature of 101°. He only made complaint of pain in abdomen, and especially in lower part. On examination I found belly a little distended; it did not move well on respiration and surface was blistered as result of hot applications. Some rigidity, but not marked, and mostly in the flanks and iliac regions. It was especially noticeable that, while splenic dullness was considerably increased, normal liver dullness was replaced by a resonant note and there was no dullness in flanks.

I could only agree with the diagnosis of probable rupture of a typhoid ulcer. Under local anæsthesia I made a small subumbilical incision in mid-line. As soon as peritoneum was opened free blood escaped and a piece of omentum that presented had some blood clot entangled in its meshes, but there was no gas. The lower ileum was free from any sign of ulceration or inflammation; mesenteric glands slightly enlarged. As there was no evidence of peritonitis or fat-necrosis I recognised that I was probably dealing with an example of spontaneous rupture of spleen. Patient was anæsthetised with ether and incision prolonged. Quite a large amount of free blood escaped, though not nearly so much as in most cases of traumatic rupture. On passing my hand up to splenic area I found a considerable amount of soft blood clot, and about the middle of its outer convex surface I felt what I took to be a rent about 1½ inches long, and running forwards towards anterior border. It was occupied by firm blood clot, and though evidently the source of hæmorrhage it was presumably not then bleeding. There were no adhesions. Nothing further was done beyond rapidly closing incision. Although patient was very ill, and caused Captain A. H. Haddon, who gave the anæsthetic, some anxiety, he really stood the operation quite well and became conscious during administration of subcutaneous infusion of saline.

At this stage I feel that I ought to explain why I did not expose the spleen or attempt to interfere with the rupture directly. The temptation to inspect the lesion was very strong, but patient was exceedingly ill and it would have necessitated either a prolongation of incision to epigastrium or a second independent incision below left costal margin. Having exposed the spleen, I would either have had to remove it or trust to suture or perhaps gauze-packing. Further, from previous experience I knew quite well that a moderate rupture of the spleen could be well trusted to take care of itself, measures having been taken to tide the patient over the catastrophe of the immediate blood loss, and I thought that the condition of the patient demanded these temporising methods. In the light of subsequent events I regret that I felt compelled to adopt this course, for I believe that the best interests of the patient would really have been served by running what then appeared the very much greater risk incurred in an effort to expose the spleen.

Films made from blood in peritoneum were examined for malaria, but the parasites were not found. Unfortunately no attempt was made to inoculate culture-media.

On the day after operation patient was fairly well and had almost completely recovered from the shock. Temperature 100° and pulse 122 and of better tension; there had been no vomiting. On Sept. 11th he had some loose motions, containing blood, and on the 12th the left leg was found to be swollen and œdematous; no albumin in urine and condition probably due to femoral thrombosis. By the 13th the tongue, which had been very dirty, was cleaning up; wound dressed and found healed; abdomen moved freely; no tenderness. On this day I noticed two hæmorrhagic patches on back of either hand about size of a sixpence; they appeared evidence of mild scurvy; gums absolutely healthy and no other confirmatory signs. Between the 13th and 21st condition varied considerably, and for some days he was very ill, with temperature between 100° and 101° and pulse about 110. I suspected a pelvic abscess, but this was not confirmed by rectal examination. On Sept. 16th he was exceptionally ill and temperature again suggested malaria, but plasmodium not found; he had several loose motions. In spite of negative blood examination he was given 15 grains of hydrochloride of quinine by intramuscular injection and next day seemed better, but improvement only evanescent. About this time dullness of left base increased, and I withdrew a small quantity of blood-stained fluid. Breathing gradually became more embarrassed, and I have no doubt that in later stages the fluid in left pleura increased very rapidly. About Sept. 29th he vomited; no complaint of abdominal pain; tongue clean and moist. A small subcutaneous hæmorrhage was noticed on left arm and for first time a thin red line along margins of gums. From this time progress was steadily downhill. Breathing became more and more rapid; some cyanosis. He took food badly, was delirious at night, and rapidly lost flesh. Death on Oct. 4th, just four weeks after operation.

Post-mortem.—I made a necropsy three and a half hours after death. Abdominal scar was stretched and of deep purple colour; when epidermis covering it was divided, deeper parts were found completely occupied by recent blood clot and without least evidence of union. Catgut sutures absorbed; no naked-eye evidence of sepsis.[1] The small intestine area and right side of abdomen presented appearances associated with aseptic absorption of free blood in peritoneum. Some soft shaggy vascularised adhesions were present over dome of liver and among coils of small intestines. Great omentum tucked up, or shrunken, so as to lie along lower border of colon. Both splenic flexure and fundus of stomach with left lobe of liver were adherent to one another and to parietes, obscuring splenic region. There was a collection of fluid in left extremity of lesser sac, and on separating adhesions to parietes, the latter was opened into, allowing about half a pint of very offensive, thin, pink-coloured fluid to escape. The cavity was the much diminished lesser sac, and in addition to the fluid there was some blood clot and the wall was covered by an attempt at granulation tissue. Right half of sac, including foramen of Winslow, obliterated. Spleen surrounded by small amount of same sort of fluid as occupied lesser sac. Organ very friable and presented two areas almost completely separated and recognised as necrotic infarcts. The larger area was a wedge-shaped mass of tissue, about 1½ inches in longest diameter (transverse to long axis of organ), and 1 inch in shorter. It lay so loosely attached to its bed that it fell out by its own weight when specimen was turned over. It was of a dirty yellow colour and had a ragged surface without any sign of repair, in fact it looked exactly what it represented—a mass of necrotic spleen tissue. The bed in which it had lain resembled the crater of a volcano, and was largely advanced towards repair, its surface being quite smooth as though

[1] This, I take it, was an example of "disunion," a phenomenon almost peculiar to scurvy. When the wound was dressed at the end of a week, it was found to be perfectly healed and on the sixteenth day it looked as though completely consolidated. Had it been in the ununited condition found post mortem, for any length of time before death, I should have expected it to have given way with prolapse of intestine. In addition to hæmorrhagic patches on back of hands and small hæmorrhage on left arm previously mentioned, there were also some petechiæ on skin of abdominal wall and on the limbs. In reflecting the structures from front of chest I also came across a small localised hæmorrhage in substance of pectoral muscle. Evidences of a mild type of scurvy were quite common in patients in the last stages of diseases like enteric and dysentery, in which feeding on sterilised foods for long periods had been necessary, and I always looked upon the condition as of similar origin to the scurvy rickets of young children (Barlow's disease).

covered by a layer of endothelium. The other infarct, at apex of spleen, was exactly similar though only half the size. Condition of splenic artery and vein was not carefully investigated. In left pleural cavity was about two pints of thin hæmorrhagic fluid, without any naked-eye evidence of infection. Anterior border of corresponding lung was loosely adherent to parietal pleura, while base was firmly glued to upper surface of diaphragm. On separating latter from the lung two large areas of purulent lymph were exposed, and there was a most offensive odour recalling that in gangrene of lung. Substance of lower lobe carnefied, but no real consolidation; infective process was limited to pleural surface, having evidently extended up through diaphragm. Right lung and pleural cavity normal. Little blood-stained fluid in pericardium; two hæmorrhagic areas on surface of heart. The organ itself was enlarged, principally due to increase in size of right side, which was crammed full of blood-clot. At extreme apex of right ventricle was a small mass of tissue about size of walnut, oval in shape and pinkish in colour, and entangled in bundles of heart muscle. Its central part was broken down into a little cavity containing creamy pus. No endocarditis, but heart muscle pale and flabby. Liver slightly nutmeg and fatty, but no infected areas, though tip of left lobe had formed part of wall of cavity containing infarct situated at upper pole of spleen. The lower four or five feet of ileum and greater part of colon were examined, but without discovering any trace of ulceration, recent or remote. Mesenteric glands only very moderately enlarged. No gross pathological changes in kidneys. Specimens of pus were examined from: (*a*) mass in right ventricle; (*b*) fluid around spleen; and (*c*) that in lesser sac. They all gave the coli reactions, probably indicating a general *Bacillus coli* infection.

I presume that in this case the course of events was thrombosis of some branches of the splenic vessels, followed by infarction, mild infection, and separation of the infarcted areas. It was probably when the latter process began that the hæmorrhage into the peritoneum occurred.

I am indebted to Colonel W. H. Starr for permission to use the notes of the first case, and to Lieutenant-Colonel J. R. Bond for a similar privilege with regard to the second, and to both for their interest and encouragement.

PRIMARY SUTURE AND UNION OF OPERATION WOUNDS OF THE URINARY BLADDER.

BY A. RALPH THOMPSON, CH.M. MANCH., F.R.C.S. ENG.,
SURGEON IN CHARGE OF THE GENITO-URINARY DEPARTMENT, GUY'S HOSPITAL.

MUCH ingenuity has been exercised for some time now in devising more or less adequate schemes for dealing with an open suprapubic wound of the bladder. The wounds which result from operations of such a nature as suprapubic prostatectomy occur, of necessity, most frequently in middle-aged or old people. In those cases of suprapubic operation in which some apparatus is fitted in order to prevent the running of urine and chemical fluids over the adjacent parts the skin is very liable to become exposed to the dangers of sepsis and trauma. On the other hand, in those cases in which no such measures are adopted the constant wetting of the dressing and consequent evaporation are liable to give the patient cold and retard his recovery.

Owing to the constant care exercised by my dressers at Guy's Hospital during the past four years I have been enabled to perform a number of operations, such as suprapubic prostatectomy, removal of a vesical growth, and retrograde catheterism, with primary suture of the bladder wall and superficial tissues.

Primary union occurring in bladder wounds of an operative nature offers such tremendous advantages over other methods of dealing with bladder wounds, that I am inclined to think it should be aimed at more frequently than it is. Cases of enlarged prostate and growth of the bladder which demand operation are put off frequently, in my experience, by both patients and their medical attendants, because they dread the inconvenience, labour, trouble, and danger involved by an open wound of the bladder. If, then, this difficulty of the open wound in a bladder can be in a reasonable number of cases overcome, we may expect to see enlarged prostates more frequently removed, and growth of the bladder extirpated, not so much for the purpose of averting a distressing and painful death, as is too commonly the case at present, as for rendering life pleasant and happy.

Method.

The method adopted for securing primary union in the wound following upon a suprapubic vesical operation in my cases is as follows.

After the actual disease is removed, such as an enlarged prostate or a vesical growth, steps are taken to control and prevent hæmorrhage. This is frequently quite trifling in amount, but is occasionally severe. The bladder is filled with gauze sponges which are saturated with hot boracic lotion at a temperature of 120° F. After a little time the sponges are removed and liquor hamamelidis B.P. at a similar temperature is poured into the bladder and allowed to remain there. The quantity used is about 3 ounces. A coudé catheter is then inserted into the bladder viâ the urethra, especial care being now taken that the wound shall not be contaminated, the wound being covered with cyanide gauze. The point of the catheter is laid carefully in the bladder, about one-third up the vertical height of the bladder, and the position of the catheter at this level is carefully noted in its relations to the meatus for future use, as a catheter may slip even when tied apparently securely, and it is important that it should not do so unknown to the surgeon or his assistants. The bladder wound is then exposed, and sutures are applied as follows.

The two ends of the incision in the bladder are secured with Lane's forceps, and the edges slightly everted; fine catgut sutures are then placed through the muscle wall of the bladder, as close to the mucous membrane as possible, but not through it. Each suture is tied immediately after it is passed, but not cut until all are tied, as tension upon them helps to steady the bladder.

Some difficulty is usually experienced in inserting and securing the lower sutures, but this must be done as perfectly as possible. About six or seven sutures are thus inserted, tied, and cut. The sutured part is carefully palpated in order that any holes left by suturing may be discovered and closed. The fibrous and outer muscular coats of the bladder are now secured with thicker catgut sutures, inserted in the manner of Lembert, and carefully tied, especial care being taken, as before, with the lower part of the wound. The number of sutures is, as before, six or seven.

A small gauze wick is placed in the cave of Retzius, after this space has been carefully washed with boracic lotion. If the peritoneum has been retracted upwards it is brought back into its original position on the front of the bladder, or even "encouraged" down a little lower. I think it helps the incision in the bladder wall to heal more readily. The abdominal wall is then sewn up with two rows of catgut sutures, the deeper row being placed through the rectus and pyramidalis muscles and anterior layer of the rectal sheath on each side, and the more superficial row through the superficial fascia and skin. Care should be taken to place at least one superficial suture through the skin and subjacent tissue below the wick of gauze laid in the cave of Retzius, as the edges of skin are thus much more likely to unite when the gauze is removed than when the gauze has no suture below it. I believe this to be an important point. The usual gauze dressings are then applied and the catheter is secured in the urethra.

After-treatment of wound.—The patient is returned to bed and the after-treatment is begun at once. (I always now have a spinal anæsthetic given in these cases, so that any immediate treatment necessary is more easily performed than when the patient is unconscious.) The dresser of the case washes out the bladder with normal hot sodium citrate solution; this prevents any blood from clotting. The irrigation is done with the help of a special apparatus, which I always use for the irrigation of the bladder, and which consists of two funnels, each holding four ounces of fluid, connected by long indiarubber tubes to a Y glass tube which in turn is connected up with the catheter by a short length of rubber tubing. There is in connexion with the two long tubes a double spring clip, so arranged that pressure opens one indiarubber tube and at the same time closes the other, or *vice versâ;* and thus first the clear irrigating fluid only mixes in very small quantity with the fluid from the bladder; and, secondly, the amount of fluid from the bladder can be easily compared with the amount injected. Care is taken that only four ounces of fluid are introduced, and drawn off, at each irrigation. Between the intervals of irrigation the catheter is connected with a drainage-tube having as long a drop as possible. These irrigations are continued at gradually lengthening intervals until the washings are free from blood, which usually happens within three days. For the next two or three days boric acid lotion is substituted for the sodium citrate solution, which has done its work in preventing clotting of the blood in the bladder. The gauze wick is removed upon the second day. The catheter is removed at the end of a week or 10 days, and the patient allowed up at the end of 14 days without a catheter. The sutures are removed after 14 days.

Results.

The results of this method of treating operation wounds of the bladder are detailed in the accompanying table of 13 cases. Even where a small fistula formed, it was quite small and rapidly healed, and in the case which was, relatively speaking, a failure, I do not regret having attempted primary union, as the open wound healed up remarkably quickly—I fancy much more quickly than if primary union had not been attempted.

Summary of Cases of Primary Union after Operation upon Urinary Bladder.

Total number of cases ...	13	Partial success	2
Average age of patients...	58	Success	10
Failure...	1	Deaths...	0

These cases have been reported by me as, although they are too few to form general conclusions from, they do show that much of the trouble incident to an open bladder wound may be overcome by obtaining primary union. I do not at present attempt primary union in cases in which (1) there is marked cystitis, (2) there is considerable renal insufficiency, (3) bleeding cannot be sufficiently arrested at the time of operation, or (4) too much unavoidable damage to the bladder wall has been done.

The good result indicated in the table is due chiefly to the assiduous after-care of my dressers, who, however, realise that, after the first two or three days, there is infinitely less trouble involved than when the wound is left open. Moreover, one is greatly assisted in these cases by the temporary partial suppression of renal activity which takes place, as I think, immediately after a major operation upon the bladder, and which may last for as long as 24 hours. If, however, the success of these operations, as indicated below, is in future practice justified, then it may be said that bladder surgery has advanced a considerable step forward, and been robbed of half its terrors.

Group I., Stricture of Urethra.

CASE 1.—Male, 67. ? Enlarged prostate. (Dr. L. G. Reynolds, Balham.) Suprapubic cystotomy. General anæsthetic. Primary suture of bladder and abdominal wall. Primary union. Discharged well from hospital three weeks after operation. Cystoscoped five weeks after operation. Greyish-white slough seen at fundus of bladder. Small urinary fistula formed, which healed up in ten days' time. Partial success.

CASE 2.—Male, 41. Impassable stricture. (Sir A. Fripp.) Suprapubic cystotomy. Retrograde catheterism. Internal urethrotomy. General anæsthetic. Primary suture of bladder and abdominal wall. Discharged within four weeks of operation. Union perfect. No. 14 English catheter is being passed without difficulty. Success.

Group II., Suprapubic Exploration of Bladder.

CASE 1.—Male, 35. ? Vesical neoplasm; none found. Suprapubic cystotomy. Primary suture and union of wound. Deep part of wound closed firmly. Slight retraction of skin edges. Delayed union of skin, but no urinary fistula. Partial success.

Group III., Growth of Bladder.

CASE 1.—Male, 37. Papilloma of bladder. Suprapubic cystotomy. Removal of growth. Primary suture and union. Discharged well at end of third week from operation. Success.

CASE 2.—Male, 69. Large papilloma at base of bladder. (Sir A. Fripp.) Suprapubic cystotomy. Removal of growth. Diathermy of base of bladder by Dr. C. E. Iredell. Primary suture and union of wound. Hæmatoma formed in perineum; this in part broke down, and small, quite temporary, perineal sinus formed. Success.

CASE 3.—Male, 57. Papilloma of bladder. Suprapubic cystotomy. Spinal anæsthesia. Removal of growth. Much bleeding and clotting of blood. Bladder wound reopened and left open eighth day. Recovery. Failure.

Group IV., Uncomplicated Enlarged Prostate.

CASE 1.—Male, 56. (Major Wallace Kemp, R.A.M.C. T., Kensington.) Enlarged prostate. Suprapubic cystotomy; general anæsthetic. Removal of prostate. Primary suture and union. No complications. Success.

CASE 2.—Male, 70. Very much enlarged prostate. Suprapubic cystotomy. Spinal anæsthetic. Removal of prostate. Primary suture and union. No complications except slight orchitis. Success.

CASE 3.—Male, 65. Enlarged prostate. Suprapubic cystotomy. Spinal anæsthetic. Removal of prostate. Primary suture and union. No complications. Success.

CASE 4.—Male, 64. (Mr. H. J. B. Cane, Belvedere.) Enlarged prostate. Suprapubic cystotomy; spinal anæsthetic. Removal of prostate. Primary suture and union. No complications. Success.

CASE 5.—Male, 65. (Mr. H. Cardin, Ingatestone.) Enlarged prostate. Suprapubic cystotomy; spinal anæsthetic. Removal of prostate. Primary suture and union. No complications. Success.

CASE 6.—Male, 66. (Dr. J. Steed, Staunton.) Patient very fat man. Enlarged prostate. Suprapubic cystotomy; spinal anæsthesia. Removal of prostate. Primary suture and union. No complications. Success.

Group V., Enlarged Prostate with Vesical Calculus.

CASE 1.—Male, 64. (Mr. Cane, Belvedere.) Enlarged prostate. Suprapubic cystotomy; spinal anæsthetic. Removal of prostate and three large stones. Primary suture and union. No complications. Success.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

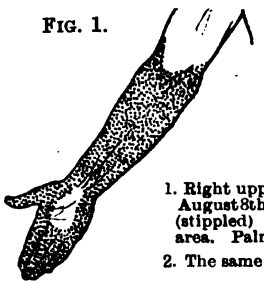
A CASE OF SYPHILITIC PERIPHERAL NEURITIS.

BY HAROLD E. THORN, M.B., B.S. LOND., M.R.C.S. ENG.,
TEMPORARY SURGEON, ROYAL NAVY.

THE following case is of some interest as far as the accurate diagnosis is concerned.

The patient, a signalman, aged 25, in H.M.S.——, in the Eastern Mediterranean Squadron, joined this ship on July 21st, 1916, from Malta. Six days later I saw him, and he gave me the following history. He had had primary and secondary syphilis in March, 1916, having been infected at Malta, and had been treated in Bighi Hospital, Malta, with two injections of galyl, one in April and the other in May. He had no mercury, but thought that he had had potassium iodide for a few days. He was examined generally on July 27th, and no signs of syphilis were found. Mercury in the form of cream (1½ gr.) was injected into the buttock and this treatment was continued weekly until Oct. 12th. Only eight days after the first injection (August 4th) the patient complained of weakness in the right arm and hand. On examination a typical right main-en-griffe was found; the right hypothenar eminence was definitely wasted and there was cutaneous anæsthesia over areas corresponding to part of the distribution of the sixth and eighth cervical and first dorsal nerves to the right forearm and hand. Massage and passive movements were ordered to be applied to the right arm daily and he was given light duty. A few terra-cotta spots were found on the trunk; these were not very definite and nothing further developed in that region. No salivation, diarrhœa, or vomiting was present. No sign or history of alcoholism or injury could be found, and as regards the former the man had not been ashore, so was exceedingly unlikely to have had excess of alcohol. No swelling in the neck or axilla could be detected; there was no blue line on the gums or other sign of plumbism; no history suggested diphtheria, influenza, tubercle, enteric, or malaria, nor was dengue, Malta fever, beri-beri, or leprosy apparent. On August 7th and 8th the patient was further examined and besides the signs found on the 4th the following details were noted: Weakness of the extensors of the right wrist; anæsthesia over the right forearm and hand, analgesia being the most extensive (see Figs. 1 and 2); touch and temperature not lost

FIG. 1.



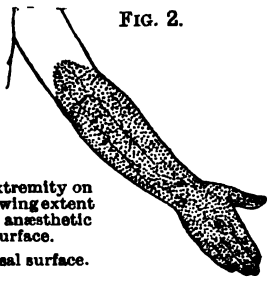


FIG. 2.

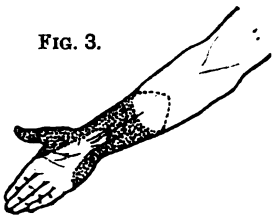

1. Right upper extremity on August 8th, showing extent (stippled) of anæsthetic area. Palmar surface.
2. The same: dorsal surface.

quite so extensively; relative hot and cold sensation unimpaired over rest of arm; circumference of right forearm a quarter of an inch smaller than left at its largest diameter, half an inch smaller at the middle. (The patient is right-handed.) The right supinator jerk was absent; the left present Both knee-jerks were present and the rest of the central nervous system was normal. No spinal disease could be detected. The patient complained of pain, and there was a discharge from the right ear; acute otitis media was found on that side. He stated that he had had recurrent similar attacks in the same ear throughout his life. Examination of the urine showed it to be neutral; specific gravity 1014; no albumin or sugar. On August 19th the membrana tympani of the right ear had healed completely after treatment locally by syringing with izal, ½ drachm to the pint, and the application of boric powder. Power in the right hand was slightly better. On the 22nd a note was made that sensation was improving. 31st: Sensation over ulnar and median nerve distribution improving. Sensation remained impaired over the dorsal area supplied by the radial (see Fig. 3). Sept. 21st: Analgesia

remained only over the radial nerve distribution; some wasting of forearm still apparent. Oct. 6th: Sensation had become normal and the muscles were improving. From Oct. 12th to Nov. 16th injections of mercury were discontinued. On Oct. 19th the right arm was practically normal and massage was discontinued. The patient was able to write perfectly well. Since then he has not had any trouble with the right arm. Injections of mercury were restarted on Nov. 16th and given weekly until Dec. 22nd. Now he is having fortnightly injections. Owing to the movements of the ship no Wassermann reactions were obtainable.

FIG. 3.

Right upper extremity on August 31st, showing diminution in extent (stippled) of anæsthetic area. Palmar surface. The dotted line indicates the upper limit on the dorsal surface.

From these observations there does not appear to me to be any doubt that the cause was syphilis; the only question about the diagnosis is whether there was peripheral neuritis due to syphilis or whether the lesion was situated anywhere else. The fact that complete recovery ensued upon mercuric treatment appears to confirm the impression that the lesion was in the peripheral nerves. The absence of pain makes pachymeningitis improbable, but this is also unusual in syphilitic neuritis. Hyperæsthesia was never present, which is unusual for neuritis of this origin. Presumably no central nerve cell lesion was present, as complete recovery would not then have occurred. The anæsthetic areas did not correspond accurately to any definite nerve roots, but nearly to peripheral nerve distributions; the palmar cutaneous branch of the median was apparently never affected.

A CASE OF FULMINATING MENINGOCOCCUS SEPTICÆMIA.

BY FREDERICK C. PYBUS, M.S.DURH., F.R.C.S. ENG.,
SURGEON TO THE HOSPITAL FOR SICK CHILDREN AND ASSISTANT SURGEON TO THE ROYAL VICTORIA INFIRMARY, NEWCASTLE-ON-TYNE.

IT would appear from the following case that death within 13 hours from meningococcal septicæmia is a calamity against which therapeutic agencies seem futile.

The patient, a girl aged 3 years, admitted to hospital as an abdominal emergency case and as such seen by me, was apparently in good health when, at about 11 A.M. on Dec. 19th, 1916, she was seized with abdominal pain and vomiting. The pain was sufficiently severe to make her cry out. The bowels were opened normally at about 2 P.M.

On admission to the Royal Victoria Infirmary, Newcastle, at 6 P.M., the child appeared very ill. Temperature 97·4° F.; pulse almost uncountable. She was slightly cyanosed and complained of abdominal pain. The house surgeon reported the case to me at about 8 P.M., stating that the child was gravely ill, that he thought he could feel a mass in the right hypochondrium, and although no blood had been passed he thought it might be a case of intussusception. I thought for a child to be so ill in such a time a massive internal strangulation would be a more probable diagnosis. I saw the patient at 9 P.M. and found her unconscious. The skin was burning hot and the temperature was found to be 103°, the pulse being uncountable. Cyanosis was present and the pupils were dilated. The abdomen presented no abnormal signs, except that the liver edge was readily palpable. On further examination petechiæ and small hæmorrhagic patches were found on the lower extremities. No signs of meningitis were present. I considered the case to be one of intense septicæmia, probably due to the meningococcus. The patient died three hours later.

Owing to the absence of Professor Stuart McDonald, the post-mortem examination was made by Mr. H. M. Johnston, the resident medical officer, and myself. The brain and spinal cord presented no signs of meningitis. The chest organs were normal. The abdominal organs were normal, with the exception that the liver appeared to be abnormally red in colour and that petechiæ were visible in the mucous membrane of the stomach and intestines. Cultures were made from the ventricular cerebro-spinal fluid and from the heart blood. The culture from the former was contaminated, but the heart blood gave a pure culture of the meningococcus.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF ELECTRO-THERAPEUTICS.

Dosage in Radium-therapy.

A MEETING of this section was held on May 18th, under the presidency of Dr. G. HARRISON ORTON.

Dr. J. C. MOTTRAM and Mr. SIDNEY RUSS contributed a paper on "A Study in Dosage in Radium Therapy."

The patient, a woman, aged 56, was the subject of carcinoma of the breast, very slow-growing, with a large number of subcutaneous nodules on both sides of the trunk, a total of 80, which made it possible for some to be treated in various ways, while others were left as controls. The primary growth in the breast was near the nipple, in the superficial tissues. The primary growth was treated with X rays, but without benefit; the skin over the growth ulcerated, involving the nipple. The ulcer became covered with a dry crust, in which condition it remained until the present treatment by radium was commenced. Three mgm. of radium were applied over an area of 45 sq. cm., screened through 1 mm. of lead and two layers of lint. Shortly after its removal a transient erythema was noticed, and subsequently the crust covering the ulcer fell off, showing the skin beneath healed. The carcinomatous mass had not disappeared, and that was the present condition of the growth. Some of the nodules which had been under experimental treatment disappeared. There had been no glandular involvement nor metastasis in other organs.

This condition, called by some "disseminated scirrhus," was supposed to spread by the lymphatics. The changes in the skin observed formed a progressive series. The earliest change was an erythema, which occurred in almost every case. In many cases a slight scaliness was seen, but the radium produced no other change. In a few nodules there was transient œdema, and in some the application was followed by erythema and pigmentation, the latter persisting for months. The effect of radium on the nodules varied from complete disappearance to no appreciable change. In some there was caused a stoppage of growth, either temporary or permanent. It was not possible to measure the nodules from week to week, owing to their varying depth; the only criterion which could be employed was the time at which a nodule disappeared. The two main aspects of a study of dosage in radium were those on surface condition and the effects on subcutaneous nodules and the skin covering them. A question which the observers set out to answer was: Supposing the skin were made to absorb the same amount of beta ray energy as gamma ray energy, were the biological effects equal? To answer that they adjusted the radiation so that the first millimetre of skin absorbed as much beta energy as it absorbed gamma energy. This meant a pouring on to the skin of a large quantity of gamma energy owing to its absorption being so much less. As tissue became penetrated beta energy fell off very rapidly, so that at about a centimetre depth the available energy was only 1 per cent. to 2 per cent. of the original intensity. The gamma energy at that depth was about ten times as much; these rays also produced more profound changes in the skin than did the beta rays. The series of symptoms observed with varying doses of both kinds of irradiation, and embodied in a table, included erythema, scaliness, pigmentation, exudate, &c. These observations were all made with a dose of 7 mgm. When the dose was much diminished—namely, to 1/80th—and the time of application correspondingly increased, some of the more definite changes previously noted did not occur: only erythema and scaliness, sometimes pigmentation, but not exudate, and the disappearance of the nodule. A sequential study concerned the effects observed through various screenings.

SECTION OF OTOLOGY.

Cases and Specimens.—Diseases of the Ear and Recruiting.

A MEETING of this section was held on May 18th, under the presidency of Mr. H. J. MARRIAGE.

Dr. DAN MCKENZIE gave an account of 250 specimens of temporal bone which had been handed to him by Mr. A. L. Whitehead, of Leeds, and which he had examined in order to obtain measurements of the Fallopian canal. The results he presented in tabular form, arranged according to the age and sex of the patients. He obtained from the specimens

some thirty interesting facts. 35 per cent. of the bones were, clinically, of the infantile type. The information thus obtained had an important bearing on the performance of the radical mastoid operation. 50 per cent. of the specimens from people over 50 years of age showed dehiscence, probably due to the osteoporosis which occurred with advancing years.

Mr. J. F. O'MALLEY showed a remarkable case of cerebro-spinal fluid escaping from the ear during a period of 12 months. The patient, a man aged 27, had a mastoid operation performed 10½ years ago. After six years a polypus formed and was removed. During the ensuing two years polypi were removed twice, and again 18 months ago. Soon after the last of these operations the ear began to drip, and was worse at night. When Mr. O'Malley saw the patient the right external meatus, from which the dripping took place, was blocked by a smooth cyst-like swelling. This was found to be the scar-tissue lining of the mastoid cavity, raised by the cerebro-spinal fluid from the bony facial ridge and antral cavity. He reopened the mastoid and cleared out the old scar-tissue, but he could not localise the bony defect. As the dressings were still soaked all of them were removed, when the operation cavity was found to be bathed in pus. Despite careful treatment, the cerebro-spinal fluid continued to soak through the dressings for six weeks. The cavity, however, was now more free from pus, and he dusted daily with boric powder and packed firmly with sterile gauze. The point of escape of the fluid was found to be the posterior part of the attic. Even as late as 3½ months from the operation 1½ dr. of fluid collected in four hours. The patient must have lost about 1½ gallons of the fluid in 3 months.

Mr. C. E. WEST, Mr. SYDNEY SCOTT, Mr. R. LAKE, Mr. H. J. BANKS DAVIS, and Dr. KELSON discussed the case.

Mr. SCOTT showed a case of Squamous-celled Carcinoma of the External Auditory Meatus and Tympanum in a woman aged 22.

Captain G. J. JENKINS opened a discussion on the subject of Diseases of the Ear in Relation to Recruiting, which was deferred to the next meeting of the section.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

Hallucinations in the Sane.

THE usual quarterly meeting of the association was held at the rooms of the Medical Society of London on May 15th. Lieutenant-Colonel D. G. THOMSON, R.A.M.C., presiding, made sympathetic reference to the decease of the following members: Dr. R. B. Smyth, Dr. T. Seymour Tuke, Dr. William Rawes, Dr. J. W. A. Murdoch, Captain G. Swinnerton Blandy, R.A.M.C., M.C.

Dr. ROBERT HUNTER STEEN read a paper on Hallucinations in the Sane, dividing his subject into (*a*) hallucinations the result of agencies operating upon the brain or nerves, and (*b*) those of mental origin. Among the former he placed toxins, both exogenous and endogenous, disorders of brain circulation, disease of end-organs, after images, and brain diseases of obscure pathology, such as epilepsy and migraine, and in the second category he placed cases in which, so far as present knowledge goes, a physical agency was unknown, including suggestion, hypnotism, crystal-gazing, clairvoyance, hysteria, somnambulism, multiple personality, hypnagogic visions, dreams, hallucinations in history, collective hallucinations, so-called telepathy, and hallucinations the result of a complex. Among the drugs which may produce this effect he included alcohol, absinthe, ether, stramonium, belladonna, hyoscyamus, nitrous oxide, chloroform, mercury, lead, and santonin. In the author's view hallucinations did occur in the sane, and cases met with in the sane should be intensively studied. This study was especially necessary in borderland or hysterical cases, and there seemed to him no reason to think that hallucinations in the sane differed from those in the insane, and each could be produced by toxins. He therefore thought it probable that hallucinations in the insane could be better studied from the psychological rather than the physiological standpoint. In every case presenting hallucinations he considered that some process of dissociation was at work, and this was supported by the fact that hallucinations were met with in cases of multiple personality.

Dr. C. A. MERCIER sent a contribution to the discussion, and the subject was further debated by Sir GEORGE SAVAGE, Dr. E. S. PASMORE, Dr. CARSWELL, and the PRESIDENT, and Dr. STEEN replied.

Reviews and Notices of Books.

Health and Empire. By FRANCIS FREMANTLE, F.R.C.P., F.R.C.S., Lieut.-Colonel, R.A.M.C. (T.F.). Second edition. London: Heath Cranton, Limited. 1917. Pp. 369. 5*s.* net.—In 1903 Colonel Fremantle took advantage of prolonged leave from official duties and made an extensive tour of the world. Starting by acting for a winter as a plague medical officer in Lahore and Amritsar, he visited other parts of India, Burma, Singapore and Malay, Cochin-China, Hong-Kong, Canton, and Shanghai, reaching Japan shortly after the outbreak of war between that country and Russia. After a short experience of war in Northern China he turned eastwards to San Francisco, went up to Vancouver, passed through Winnipeg, Chicago, and St. Louis, leaving the second winter free for visits to Paris, Geneva, Berlin, and Hamburg. Throughout his travels he was engaged upon a personal investigation of public health conditions of the world under various climates and rules, and he summed up his experiences in an interesting and valuable book which was reviewed in THE LANCET some six years ago. In this book his special aim was to persuade the public of the significance of public health problems as modified by various races and systems of government under which they arise, and his suggestion to form a permanent Advisory Council in London of experienced health officers, one from each of the Dominion Governments, is worth recalling at the present time, when the centralisation of public health administration is occupying so much attention.

Serving now with the Army in Salonica, Egypt, and Mesopotamia, he has found that the book will be very pertinent to the times that must succeed the war, and in a second edition, practically unaltered, repeats his urgent message that the future of our Empire must rest not on treaties and tariffs, armies and fleets, so much as on organised defence against disease. In the preface to the second edition he writes from Mesopotamia, quite in ignorance how apposite the words would be: "In civil government, while each department may have its medical adviser and him essentially a preventer of disease, so must there be one health department, call it what you will, to direct all the medical and sanitary services of the country and to be generally responsible for the health of the nation." Medical opinion is now solidly of this belief, and Colonel Fremantle's informing book will supply lay readers with unanswerable evidence that throughout our vast Empire the prevention of disease should be the first care.

The Weird Adventures of Professor Delupine of the Sorbonne. By GEORGE LINDSAY JOHNSON, F.R.C.S. London: George Routledge. 1917. Pp. 344. 6*s.*—Mr. George Lindsay Johnson appears to have been much impressed by some visits which he paid to the Salpêtrière Hospital with the view of inquiring into the phenomena of spiritualism. The weird adventures, which he narrates, were told to him as actual occurrences by "a professor of world-wide fame," and he has written them down with disguises of names, the object being "to clothe the real facts with a halo of romance." We credit Mr. Johnson with believing what he was told, as he alludes to the professor's story as "real facts," but we think that he displays more capacity for believing than he is likely to find among his readers. That will be due partly to the fact that he is quite unable to tell a story in a way that might be expected to produce any effect upon the intelligence of others.

The Bird of Life. By GERTRUDE VAUGHAN. London: Chapman and Hall. 1917. Pp. 309. 5*s.* net.—Much of this book is the result of accurate observation, but the heroine would have been a more interesting person if the exact career which she leads had not been, in its various episodes, led by the different heroines of other twentieth century novels. The book is very well written.

The Cameroons. By ALBERT F. CALVERT, F.C.S. London: T. Werner Laurie. 1917. 200 plates. Pp. 82 and xxxi. 6*s.* net.—As a faithful study of the origin and development of the colonial power of Germany this small book makes instructive reading. The text is very brief, but full of facts, while many of the numerous reproductions of topical scenes are explanatory of it. We did not find the author's map, plate 200, very helpful.

THE LANCET.

LONDON: SATURDAY, MAY 26, 1917.

The Study of Function in Disease.

THE routine examination of large numbers of adolescent and adult males necessitated by the needs of the naval and military services of this country has served to focus attention upon two very old and difficult problems—namely, the significance of cardiac murmurs and the test of the functional efficiency of the heart and circulation, particularly in those persons in whom the cardiac physical signs show some departure from the normal. Among the many important contributions to the study of the circulation made by Sir JAMES MACKENZIE, none are of greater practical value than his analysis of the varieties of cardiac irregularity with their significance, leading to insistence upon the necessity in all cases of apparent cardiac abnormality of applying some test of the functional capacity or efficiency of this organ from a mechanical point of view. His forceful and downright championship of these matters has involved him in more than one controversy. We publish in another column a long letter from him replying to critics, who accuse him of lack of reverence for those great clinicians of the past, by whose careful observation and record of symptoms and physical signs the foundations of our knowledge of heart disease were laid and the application of the newer methods to the study of function rendered possible. In commenting on the recent Lumleian lectures we suggested that the utilitarian value of recent cardiac work had escaped some of the critics of modern research, but the pioneer has his failings also. With Sir JAMES MACKENZIE'S letter we are in accord, but we feel that he has some of the impatience and intolerance of the pioneer. He pays a generous tribute to past workers, but we confess we do not quite understand his statement that in the literature in the English, French, and German languages he has not found a single case where the condition of the heart was clearly detailed and the reaction intelligently described.

Five years ago the late Sir JAMES F. GOODHART delivered a thoughtful and arresting Harveian oration before the Royal College of Physicians of London on the Passing of Morbid Anatomy. He pointed out the change in our point of view of pathological problems, developed within his own memory, whereby the processes of disease rather than their terminal effects were studied. The fruitful nature from the practical standpoint of this change must be apparent. It is in some such sense that we construe the main thesis of Sir JAMES MACKENZIE'S letter as a plea for the study of function rather than of state in disease; in other words, he would have us treat the condition of the patient with some disordered organ or system as a dynamic and not as a static problem. With this view we are in full sympathy, the more so that it is obviously of wider application than in the field of cardiology. The study of the patient, of his symptoms, and of their variation in relation to special demands made upon his several organs is a truly scientific mode of investigation, and it has already led to practical results. It is also a wholesome reaction against placing too great stress upon laboratory methods in the diagnosis and treatment of disease, because it inculcates a close study of the patient and the due perspective of symptoms, signs, and laboratory results. Sir JAMES MACKENZIE has frequently and in forceful manner insisted on this conception in relation to disorders of circulatory function, and his teaching is now generally accepted and followed. It is necessary for correct diagnosis and useful prognosis and for effective treatment to observe the patient and the variations in his symptoms and physical signs under conditions of effort or even stress.

Many other examples of the fruitful results of the application of this method of studying function and organic reactions will doubtless occur to our readers, but we may perhaps draw attention to a few of them. The study of renal function in health and disease by urologists has helped to raise this branch of surgery almost to the rank of an exact science, and has led to highly satisfactory advances in diagnosis and treatment. The functional efficiency of either kidney and the adequacy of the total excretory function can now be measured accurately, with the result that diagnosis, the decision as to what cases are suitable for operation, and the effects of treatment have all been greatly improved. The problems in medical diseases of the kidney are complex and treatment is difficult owing often to the irreparable nature of the damage, but there can be no doubt that there is here a fruitful field for research. In diseases of the lungs, more especially tuberculosis, the same principles are being applied, haltingly perhaps, while the search for an adequate specific treatment goes on. Hygienic-dietetic treatment in skilled hands demands the close personal study of each individual patient and the adjustment of the patient's daily life according to the state of his lesions and his response to effort, whether in the form of graded walks and rest or graduated labour. The day has long gone by when prognosis and treatment in this disease were appraised from the physical signs only; to-day symptoms, the temperature-chart and its reactions to rest and effort, the physical signs, the sputum, and even, where practicable, the blood reactions are all duly weighed in dealing with the outlook of the patient, his chances of recovery, and his ability to return to ordinary life or to work. A wide general recognition of these facts is desirable, as it would make for earlier and more accurate diagnosis, and for more careful selection of cases for sanatorium and other modes of treatment. The field for similar methods in diseases of the nervous system, both functional and organic, widens as diagnosis becomes more accurate and our knowledge of function of nerve structures increases. The principle will be applied to the symptoms produced by every organ in the body, and we cordially welcome Sir JAMES MACKENZIE'S insistence on the

scope for truly scientific research in the clinical field. There has been too great a tendency to regard clinical medicine as worked out, and to look upon the laboratory as the only place for accurate and scientific inquiry.

The Children's Crusade.

THE destructive power of infant mortality is now generally admitted, and the popularising of measures for dealing with it is the special concern of the National Baby Week Council, which held its first meeting last week. The week from July 1st to 7th is to be set aside for the following objects: To arouse the civic sense of racial responsibility in order to secure to every child his proper birthright of mental and bodily health; to inform the public of what is already being done for mothers and young children by existing agencies; and to indicate possible achievements if every citizen assumed his proper responsibility. On the need for such propaganda work opinion is not divided, and public attention has already been called to one great destroyer of child life. Sir WILLIAM OSLER, in an oration before the Medical Society of London, which we print this week, goes over the ground again in regard to the influence of venereal diseases on child production and child life. As a baby-killer the gonococcus has no great rôle, but as a misery producer it is the king among germs, responsible for 30–40 per cent. of all cases of congenital blindness and for a large proportion of sterile marriages. The case is still stronger against the *Spirochæta pallida*. Syphilis has long been the despair of the statistician, but Sir WILLIAM OSLER feels free to attribute 25 per cent. at least of the 100,000 stillbirths occurring each year in England and Wales to SCHAUDINN'S spirochæte; and of the 18,000 children dying annually before completing the first week of life, the practical pathologist and physician, he tells us, requires no statistician in order to enable him to attribute 95 per cent. of these deaths to syphilis. Venereal disease is one of the foes against which the children's crusade must be conducted to the death.

Other reasons responsible for infant mortality are variously assessed by different observers and schools of thought. In a further volume[1] just issued of a report to the Carnegie United Kingdom Trust, Dr. E. COEY BIGGER, the Medical Commissioner of the Local Government Board for Ireland, enumerates ten factors in the order of importance which he attributes to them in relation to the welfare of infants. He takes, as his first factors, the care of the mother before, during, and after labour and the advice given as to the management of the child. The factors which immediately follow—the economic conditions of the family, the domestic surroundings of the infant, the extra-domestic surroundings of the home, the health and habits of mother and father—have, for Dr. BIGGER, less importance than supervision of the mother's health and friendly advice tendered to her in regard to her child. On this point practical unanimity prevails amongst those who have had large experience in child-welfare work. It is therefore to the health visitor that the National Baby Week Council looks as one of the main agents of child welfare. A compendious report just issued by the Local Government Board for England gives the most recent statistical information. Just over 600 whole-time health visitors are now available in Great Britain to visit 700,000 babies, and only 800 to 900 infant-welfare and maternity centres are in existence where the Council consider 8000 to 9000 are needed. Hence, one of its main objects is to stimulate local authorities in dealing with these matters. One London borough is noteworthy for its refusal, recently emphasised, to appoint health visitors at all on the ground that no evidence has yet been adduced indicating that such appointments would accelerate the progressive fall in the infantile death-rate now taking place in the borough. It is, however, very difficult to interpret the remarkable drop in the figures for infant mortality occurring between 1915 and 1916 in the great towns and urban districts of the Tyne on any other ground than that of increased care for mother and child. Economic conditions have long been good and housing has not materially altered during the time. The National Baby Week Council should have no difficulty in making out a good case for the multiplication of health visitors.

The discretion of the medical profession in the treatment of infantile disorders will not be infringed by the employment of the agency of child welfare centres, while the whole campaign of National Baby Week is based on the coöperation of the general practitioner. Health visitor and welfare centre are what Dr. J. W. BALLANTYNE has called "listening posts" to detect impending danger and ward against it. In and by them health principles are inculcated; their object is to maintain health and not to treat illness. In so far as they are successful in their aim they strike at the root of medical practice; but this is inevitable, and the medical man himself is always in the position of a person engaged in sawing off the branch of the tree on which he is sitting. The Association of Infant Welfare and Maternity Centres does not affiliate local centres to itself unless and until they have a medical person in charge of the infant consultations attached to the centre. Organisation of the child-welfare campaign by some central authority will have the advantage of securing a broad view of the complicated factors—medical, hygienic, social, racial—at their beneficent work, while not excluding the coöperation of the general practitioner at the periphery. To us any local welfare scheme is unthinkable without the active interest and coöperation of all the general practitioners in the district. Nor does the memorandum of the Women's Coöperative Guild on the national care of maternity, as we understand it, necessarily clash with the interests of general practice. The Guild pleads for a strong Central Maternity Department at the proposed Ministry of Health and for the compulsory appointment of maternity committees by local public health authorities. The plea is ably framed, and such action may well be another line of attack in a campaign of many fronts.

[1] Two volumes of this report were noticed in THE LANCET of May 5th, p. 693.

Annotations.

"Ne quid nimis."

THE TREATMENT OF THE WAR CRIPPLE: STATEMENT BY THE MINISTER OF PENSIONS.

THE position of the war cripple has for long been a somewhat obscure one, and a flood of fresh light has been shed upon it by the important statements made last week by Mr. G. N. Barnes, M.P., Minister of Pensions, in answer to questions put to him by members of a deputation from the British Medical Association. The deputation included the Chairmen of Council and of the Insurance Acts and Hospitals Committees, and the medical secretary of the Association. The Insurance Commissioners were also represented. With regard to the status of the discharged disabled soldier under treatment, Mr. Barnes said that the question of the retention of the men in military hospitals and under military control might be regarded as settled. The War Office had agreed to keep the men in military hospitals as long as room could be found for them there, to give them certain curative and manual treatment, and on discharge to hand them over to the care of the local Pensions &c. Statutory Committees. These committees would also be responsible for the men when, on the conclusion of the war, many military hospitals were disbanded. For the treatment of the war cripple after the war three alternatives would be present: first, continuance of treatment at the military hospital, where this continued to exist; secondly, at a civilian hospital, if one was available; thirdly, failing both of these, treatment by the ordinary practitioner or the specialist according to the requirement of the individual case. Mr. Barnes added that he was committed to the provision of special treatment for the disabled man, whether within or without a hospital, and to the expense of such treatment, quite apart from any domiciliary treatment to which the man was entitled as an insured person. The small number of non-insured discharged men would, he said, be dealt with also by the Insurance Commissioners, retaining the same choice of doctor as insured persons possess. In regard to the additional cost of such domiciliary treatment, Mr. Barnes said that it had been decided to watch events and to compare the results with the experience of pre-war years. Approved Societies had assumed, he said, that there would be additional sickness and consequent increased financial risk. On the other side it had been urged that the open-air life and physical training of the Service would result in a diminished sickness incidence. Mr. Barnes laid on the House of Commons the primary responsibility for the fact that the medical profession was so slightly represented on the central and local Pensions Committees, adding that he was taking steps to remedy the omission. A circular, he said, had been issued by the central committee advising all the local bodies to avail themselves of the services of the practitioners in their district, and in particular to appoint medical men on the disablement subcommittees. Every local committee, he said, should have its medical adviser. For the Central Advisory Committee Mr. Barnes welcomed the nomination of three or four persons by the British Medical Association, with the addition of a consulting physician and surgeon nominated by the English Royal Colleges. Mr. Barnes's statement heralds, we hope, the beginning of an intelligent and comprehensive treatment of a difficult problem.

TRENCH FEVER AND TRENCH SHIN.

WE publish in another column an interesting contribution to the pathology of trench fever by Dr. H. Moreland McCrea, which tends to confirmation of the view that this condition is caused by a spirochæte, since observations on the Wassermann reaction made by Dr. W. E. Carnegie Dickson gave a positive result in the vast majority of cases, and treatment by galyl and grey oil gave relief in some cases and rendered the Wassermann reaction negative. In THE LANCET of March 3rd we commented upon the observations of Professor Riemer, who obtained spirochætes from the blood in this disease and was able to cultivate them, though he hesitated to assert that the spirochæte was the cause. Dr. McCrea and Dr. Carnegie Dickson's observations take the proof a stage further, and if the spirochætes are constantly demonstrated, or if they can be proved to be infective in similar fashion for animals, the demonstration will be complete. It seems to be clear that the more chronic forms of trench fever are less typical than the acute form, the description of the latter by different observers being singularly uniform. The paper we published in last week's issue of THE LANCET by Lieutenant-Colonel Graham Chambers on Trench Shin raises an interesting question. The condition, as he admits, presents many points of resemblance to certain chronic cases of trench fever and is by some observers considered to be of this nature. It would be of interest to find out if the spirochæte found in trench fever is also present in trench shin or if the Wassermann reaction is positive in cases of the latter condition. It is possible that the symptom-complex seen in trench fever may be produced by more than one specific organism. Lieutenant-Colonel Chambers regards trench shin as an infectious fibrositis, and his suggestion seems probable. We shall await observations upon the blood in these cases with interest, as they should throw light upon this question.

THE RE-EDUCATION OF THE BLIND.

AT the Annual Congress of the Ophthalmological Society the proceedings on one afternoon took the form of an inspection of St. Dunstan's Hostel, Regent's Park, the magnificent property placed at the disposal of the Blinded Soldiers' and Sailors' Care Committee by Mr. Otto Kahn. In the course of this visit Sir Arthur Pearson, the chairman of the Committee and President of the National Institute for the Blind, opened a discussion on the employment of the blind, to which Mr. Arnold Lawson and Mr. H. B. Grimsdale, among others, made useful contributions, and the whole subject has now received wide illumination by the issue of the report of the work of St. Dunstan's Hostel during the year ended March 31st last. At this date the blind inmates of St. Dunstan's, including the numerous annexes which have been added to the central mansion, numbered 354, while new accommodation has been provided for nearly as many more patients. The War Office has arranged now that all soldiers with badly damaged eyes shall reach St. Dunstan's

through the 2nd or 3rd London General Hospitals, and part of the success which has crowned systematic treatment has no doubt been due to the prompt sympathy and spirit of comradeship with which the new comers are received. Their re-education begins at once with simple lessons in net-making and Braille; in the workshops, where the scheme of re-education next takes them, their instruction is mainly given by men who some few months back were themselves blinded on the battle-field; and beyond the workshops expert tuition is supplied in poultry farming, massage, Braille shorthand and typewriting, and telephone operating. The report makes exhilarating reading. It is clear that these men, who have experienced what is popularly regarded as the severest physical disability which can be met with, accept under the pervading spirit of St. Dunstan's Hostel the optimistic view that though handicapped heavily they are not penalised out of all competition, but, on the other hand, may be enabled by patience to give a very good account of themselves in the race of life. We congratulate Sir Arthur Pearson and his energetic scientific coadjutors and administrative staff on the beneficent results of their efforts.

TRANSIENT PARALYSES IN MEASLES.

IN the spring of 1916 Dr. E. Aaser [1] had 190 cases of measles in Ullevaal Hospital. Seventy of these patients were adults, and had the disease in a mild form; the only complications were otitis media in four instances and pleurisy in one. The remaining 120 patients were children, of whom 65 had measles mildly, 55 in a severe form. Cultures of the nasopharyngeal mucus showed the presence of diphtheria bacilli in 13 of these 55 patients, and tracheotomy became necessary in 5, with 3 deaths; in addition, 11 of the children died from pulmonary complications. Dr. Aaser gives details of two other children who developed retention of urine and various muscular paralyses when their attack of measles was at its height, and makes no mention of the occurrence of diphtheria in either of them. The first case, a boy aged 9½, was sent in with the diagnosis of acute poliomyelitis; he had a well-marked measles eruption which had been present for a week, and for six days he had had extensive paresis of the muscles of the trunk and legs, together with urinary retention and overflow, but without any pain or hyperæsthesia. No complete paralysis could be found in the affected muscles, there was no atrophy, common sensation and sensation of heat were normal. The urinary retention lasted 17 days and was relieved by catheterisation. The muscular pareses improved after the first week, and a month after their onset the child could walk indifferently well. The second paretic patient was a child aged 4, who developed measles on April 24th, urinary retention on the 27th, and was admitted to hospital on the 29th with extensive pareses without any disturbances of sensation. Recovery from the pareses and retention followed as the measles eruption died away. Discussing the diagnosis in these two instances, Dr. Aaser says they may perhaps be regarded either as cases of abortive infantile paralysis with an initial morbilliform eruption, or as examples of measles combined with acute poliomyelitis. A third possibility—namely, that they were cases of measles with transverse myelitis, has also to be considered. Dr. Aaser notes that another case of measles occurred in a sister of the first patient a fortnight after the onset of his attack. He points out that the signs of paresis came when the attack of measles was at its worst and vanished with the rash, and he concludes that both his patients certainly did have measles. Again, neither child had the almost pathognomonic stiffness of the neck, profuse sweating, and hyperæsthesia seen in acute poliomyelitis; hence, he is inclined to think that, although a morbilliform eruption may occur in either the prodromal or the paralytic stage of infantile paralysis, and although a transient retention of the urine occurred in about a quarter of the 80 or 90 cases of acute poliomyelitis treated in his hospital four or five years ago, neither of his two patients had more than a severe and abnormal attack of measles. He has heard from a colleague of similar cases of paralysis in the course of measles, and asks for further information on the subject.

SPIRIT DUTY GRANTS TO VOLUNTARY HOSPITALS.

THE conditions under which voluntary hospitals may obtain supplies of spirit are announced, the question having been under the consideration of a Departmental Committee appointed by the Treasury since February, 1916. A circular, together with the forms for application, has been issued to the hospitals, pointing out that grants from the Exchequer are now available in relief or part relief of the duty paid upon spirit used solely for medical or surgical purposes. The grants are not available to institutions conducted for gain, but are intended to give relief in respect of payments of duty involved by the use in voluntary hospitals, supported by charitable contributions, of duty-paid spirit or drugs containing duty-paid spirit for medical use. Methylated spirit or spirit obtained free of duty under Section 3 of the Finance Act, 1902, does not come within the purview of the return, nor does the spirit used exclusively for scientific purposes, and the concession to medical requirements excludes potable spirits—e.g., brandy and whisky. In making a return figures are required as to the previous consumption of spirit based on the calendar year 1914, while grants may be applied for retrospectively as regards the years 1915 and 1916. Applicants are required to set out what proportion of spirit was allocated to out-patients and to in-patients, and the Local Government Board expect to be informed of the method by which such allocation was made, the data on which it rests, and the definition of "new out-patient" adopted by the hospital. A copy of the printed report of the hospital is asked for in regard to each of the years 1914, 1915, and 1916 respectively, and when the printed reports do not show separately the receipts other than from charitable contributions, a statement of such receipts is required. As to the category of charitable contributions, those principally excluded from this are subsidies from State or municipal funds, payments made to the hospital in respect of the supply of nurses, by patients, or by the War Office or Admiralty connected with the accommodation of sailors or soldiers. To sum up, the returns come under four headings: (1) Quantities of alcohol used in the year ending Dec. 31st, 1914, for medical and surgical purposes only; (2) amount of solution of iodine 2 per cent. made with duty-paid alcohol, if not

made in hospital; (3) the proportion of the total amount of 90 per cent. alcohol represented by the above uses for (*a*) in-patients and (*b*) out-patients, and the average amount of duty-paid alcohol 90 per cent. represented by the above used (*a*) per in-patient, (*b*) per out-patient; and (4) the receipts for the years 1914, 1915, and 1916 respectively from other than charitable contributions.

AURICULAR FLUTTER DISCOVERED BY RADIOSCOPY.

IN the *Journal of the American Medical Association* of March 17th Dr. G. W. Holmes and Dr. P. D. White have described a case in which auricular flutter was discovered in what appears to be a novel manner—by radioscopy. A painter and paper-hanger, aged 62 years, was referred to the Massachusetts General Hospital for diagnosis. He had been well until four months previously, when attacks of pain in the region of the umbilicus began. They were most frequent in the early morning, awaking him about 2 o'clock and compelling him to rise and pace the floor. Gradually the pain had become more persistent and was present much of the time. Hot applications gave some relief. There was no nausea or vomiting. No relation could be discovered between the time or kind of the meals and the pain. Yet the patient complained of indigestion, was afraid to eat much, and had lost 30 lb. in the four months. He was slightly constipated. There was no dyspnœa or præcordial pain. On examination he was pale and under weight. All the teeth were artificial and the tongue was coated. Percussion showed slight enlargement of the heart. The action was regular and rapid (115 to the minute). The sounds were faint and clear. Radioscopy after a bismuth meal did not show any abnormality of the gastro-intestinal tract. The right and left borders of the heart were then clearly outlined, when the left was seen to be pulsating regularly at the rate of 115 to the minute and the right at twice that rate. Auricular flutter was diagnosed, and the diagnosis confirmed by the electrocardiograph, which showed auricular flutter with a 2:1 a.-v. block. Right vagal pressure increased instantly the grade of the block, bringing out clearly the separate auricular deflections. The case suggests a possibly fruitful form of investigation in an obscure group of cases.

MEDICAL MUSEUMS.

LARGE and important questions came up for discussion at the recent annual meeting, held in New York, of the American Section of the International Association of Medical Museums. This section represents the leading medical museums and laboratories of the United States and Canada, and is presided over by Dr. O. Klotz, of Pittsburgh, Pa., Dr. Maude E. Abbott, of McGill University, being secretary-treasurer. The session opened with the despatch of a telegram to Washington placing the services of its workers and resources in its special field of research at the disposal of the National Committee in the present emergency. The establishment of a central bureau for the permanent preservation of the results of scientific research, especially histological material, to be used for purposes of study by scientific workers throughout the country, was brought forward by Dr. M. C. Winternitz, of Baltimore, and a committee appointed to organise such a bureau. A discussion took place on the clashing of the time of meeting in New York of the four societies of kindred nature—viz., the American Association of Pathologists and Bacteriologists, the American Section of the Medical Museums Association, the Cancer Society, and the American Association of Immunologists. It was resolved that some sort of federation should be attempted, so as to present subjects of common interest to combined audiences. A number of papers were read on museum and laboratory technique, museum teaching, the proper presentation of the results of medical research, and kindred matters. The International Association, of which the American Section is but a part, includes in its membership most of the museum curators in this country. Most successful meetings of this Association were held in London during the International Medical Congress of 1913. The Museums Association has done much to improve the technique employed in preserving and mounting of specimens. This matter has a considerable importance at the present time, for it is necessary for the progress of military surgery that a complete record should be made of the wounds and diseases suffered by our soldiers.

THE NATIONAL COMMITTEE FOR RELIEF IN BELGIUM.

THE United States Government has assumed responsibility for the work of the Commission for Relief in Belgium, and it has been decided that the National Committee for Relief in Belgium will suspend its appeals for subscriptions to the British public. Donations received after June 1st will be held to provide for emergencies now unforeseen in connexion with relief in Belgium. This course of action is in accordance with the suggestion made by Mr. H. C. Hoover, chairman of the Relief Commission, who is now in Washington, and has the approval of His Majesty's Government and the Belgian Minister. During the existence of the National Committee, whose second annual meeting will be held at the Mansion House on June 15th, over £2,400,000 have been subscribed through its medium for the relief of Belgium. As will be seen from the letter of Dr. H. A. Des Vœux in another column, the work of the Belgian Doctors' and Pharmacists' Relief Fund continues without interruption.

TALC IN TABLETS.

Mr. Albert E. Parkes, F.I.C., has been examining medicinal tablets and finds that many of them contain quantities of talc sufficient, he suggests, to cause gastro-intestinal disturbance. Mr. Parkes states that in the process of manufacture of compressed tablets it is generally necessary to mix with the powdered drug after granulation a so-called lubricant to ensure the mass flowing freely from the hopper to the dies and also to prevent the finished tablets from sticking to the dies and to each other. Various agents have been used for this purpose, one of which is talc, or French chalk, in the use of which it is generally advised to limit the amount to 1 or 2 per cent. Many of the cheaper varieties of tablets on the market were, however, found to contain talc in amounts far exceeding this. Mr. Parkes's attention was first called to the composition of soda-mint tablets, a sample of which had caused unpleasant symptoms. They were found on analysis to contain 5·5 per cent. of insoluble matter which proved to be talc.

Fourteen different samples of these tablets were then purchased from shops in various localities, and on examination

12 of these were found to contain talc, and while three contained from 1 to 2 per cent. only, the remaining nine samples contained the following amounts respectively: 2·1, 2·6, 2·8, 3·5, 4·0, 4·6, 5·4, 5·5, and 6·5 per cent. The tablets containing the smaller amounts were better compressed and of superior finish, so that the larger amount of talc could not be justified on manufacturing grounds. The worse varieties were purchased loose and were, no doubt, cheap imitations of well-known brands. The price varied from 2*d.* per ounce for the inferior samples to 4d. for the better qualities, which were supplied in bottles. Other compressed tablets were then bought and investigated such as potassium chlorate, potassium bicarbonate, potassium bromide, ammonium bromide, lithium citrate, nux omica, quinine sulphate, calomel, aspirin, salol, antipyrin, phenacetin, and phenacetin and caffeine, and a sample each of milk tablets, bismuthated magnesia, and indigestion tablets. Twenty samples in all were examined, and ten of these, which comprised the cheaper varieties of well-known tablets, contained the following percentage amounts of talc: Nux vomica, 7·8; calomel, 5·7; aspirin, 8·1, 14·8, and 18·6; salol, 3·4; antipyrin, 1·9; phenacetin, 0·5; bismuthated magnesia, 6·0; indigestion tablets, 8·0. (The two last samples are of special interest as the tablets were recommended for digestive trouble.)

The varying amounts found tend to show that talc is used indiscriminately. It does not appear to be absolutely essential, as the tablets of certain well-known firms of manufacturers were free from it or contained it in minute quantities only. In conjunction with others,[1] Mr. Parkes has previously called attention to the practice of using talc in excessive amounts as a coating and ingredient of pills. Although no injury to health has been definitely traced to the ingestion of this substance, authorities are agreed that its unnecessary and excessive use is objectionable. In 1909, for example, the Local Government Board in a pamphlet[2] called attention to the growing habit of polishing cereals such as rice and barley with talc, and the danger to health which might follow from their use as food when so treated, and Lowe and Taylor, in THE LANCET of June 18th, 1910, report a case of pancreatic calculus in a man attributed to the consumption of rice polished with talc. Talc is a silicate of magnesium, and is almost insoluble in strong acids. The use of finely-powdered glass as a constituent of a food or drug would be unhesitatingly condemned, yet the two substances are almost indistinguishable microscopically. The ingestion of such inert siliceous matter in any but minute quantities may be attended with some risk owing to the irritation which it is liable to set up. It would be interesting to learn, Mr. Parkes concludes, if any of the victims to appendicitis and intestinal complaints have been in the habit of consuming food or drugs containing talc.

WE regret to learn the death of Dr. Major Greenwood, whose activities in the cause of Poor-law reform and medical politics generally are well-known to all our readers.

THE House of the Royal Society of Medicine, 1, Wimpole-street, London, W., will be closed on Whit-Monday, May 28th.

---

[2] Report of the Inspector of Foods, No. 8.

DONATIONS AND BEQUESTS.—By the will of the late Rev. Henry Whitehead Moss the testator left £1000 to the Salop Infirmary and £500 to the Eye, Ear, and Throat Hospital, Shrewsbury.—The late Miss Hooper, of Leamington, has left by will legacies of about £5000 or £6000 to the Birmingham and Midland Hospital for Women and the Warneford Hospital, Leamington.—The late Mr. Richard Holder Luckett, of Erdington, Warwick, has bequeathed £1400 among six Birmingham hospitals.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

TUESDAY, MAY 22ND.

THE General Medical Council commenced its session at its offices, 44, Hallam-street, W. Sir DONALD MACALISTER, the President, was in the chair.

New Members.

Dr. Edward Coey Bigger took his seat on the Council as Crown nominee for Ireland, and Mr. Holburt Jacob Waring, M.S., F.R.C.S., as representative of the Royal College of Surgeons of England.

The President's Address.

Sir DONALD MACALISTER then delivered the presidential address. He said:—

Medical practitioners and medical students continue to be called up for military service in large and increasing numbers. Of both, the numbers remaining for medical duties at home, and for the future recruitment of the profession, are so reduced as to cause some misgiving. The Professional Committees appointed under the Military Service Act in Great Britain, and the analogous Central Committee in Ireland, have done strenuous and successful work in supplying military requirements on the one hand, and in providing for the claims of civilian practice on the other. Their powers are limited; yet their energy and resource, and the general willingness of the profession to endure all things for the common cause, have helped them to overcome many obstacles. Difficulties, however, remain, which the existing organisation may be unable to meet.

The question whether the time has come for a more effective system of professional "mobilisation," that is, for a temporary measure of general control, extending to all practitioners, and directing their distribution according to the nation's need for service, has been brought by several medical bodies before Mr. Neville Chamberlain, the Director-General of National Service. He invited me, as your President, to take the chair at a Conference of representatives of the Professional Committees and of certain Government Departments held on March 14th and 15th in London. Definite proposals on the subject of the better distribution of our resources were unanimously adopted, after full discussion, by the Conference. It is understood that these proposals are under consideration by the Government; but so far I have not learned what action has been taken upon them. A similar Conference took place at the same time with representatives of the British Dental Association. Mr. Tomes and I, at the request of the Director-General, were present. The conclusions arrived at have also been communicated to the Government; but again we are unaware of the result.

In the meantime the Secretary of State for War, under pressure of a sudden emergency, has decided to apply the compulsory provisions of the Military Service Act to all medical men of military age in Great Britain. At first the application was made in a form that practically nullified the efforts of the Professional Committees to safeguard the civil population. On being made aware of this untoward result, Lord Derby modified the form of his requisition, and so restored to the Committees the opportunity of exercising their functions under the Act. I understand that now, with the support of the profession in general and of the authorities, these Committees are again busily occupied in finding a practical solution of the national problem; though the difficulties of the problem are not growing less. The sources of supply for service abroad and at home are, in fact, becoming severely straitened; and many branches of ordinary civil work must of necessity suffer curtailment. It is, in my opinion, doubtful whether, without fresh legislation, the present powers of the authorities concerned will suffice to cope with all the demands of the situation. The position of affairs, as apprehended by those who have most carefully examined it, has been clearly placed before the National Service Department and the Government. With them, not with the profession, now lies the responsibility for the next step. The loyalty to national duty hitherto shown by medical practitioners as a body gives assurance that to the limit of their power they will respond to further calls should the needs of the country make further calls imperative. But to ensure the best results from their devotion a closer coördination of competing authorities, and a more effective control of the actual distribution of medical services at home and abroad, are now much to be desired.

At the request of the Director of Recruiting I have obtained, from the deans and registrars of medical schools in the United Kingdom, a return of the number of students actually pursuing medical study in January, 1917. The results have been communicated to your Emergency Committee and to the Government. The detailed figures are given in the minutes of the Executive Committee for Feb. 26th, 1917. It appeared from the return that, while in May, 1916, the whole number of medical students was 6103 (including 1379 women), in January, 1917, the whole number was 6682 (including 1735 women). As might be expected, the increase was mainly in the first and second years. The fourth and final years, taken together, were stationary. The third year, which will supply the practitioners of 1919, numbered in January only 572 men and 261 women. Since February, however, a fresh call, extending to one group of medical students not classified as "fit for General Service," has reduced still further the numbers I have given. It is now clear that, certainly in the years 1918 and 1919, and probably in the present year, 1917, there will be a serious falling-off in the number of practitioners added to the Register. In the years 1920 and 1921, however, we may expect an increase in the number of registered practitioners, both men and women. The Director of Recruiting, in making his calls on the student youth of the nation, has had all these facts before him, and I have to acknowledge that he has given them the consideration we should expect from an officer who is himself familiar with the requirements of medical education. The conditions of paper-supply and labour have delayed the issue of the Minutes and the official Registers. A new impression of the British Pharmacopœia, 1914, will presently be required, and the cost to the Council will be considerably augmented; but in view of the national importance of the work it will not be expedient to propose the raising of the selling price beyond that fixed by the Treasury in 1914.

The use of glycerine for munitions of war has imposed close restrictions on its employment in pharmacy. Sugar also is not to be had without difficulty; and prescribers have been advised to avoid ordering the official syrups as vehicles or adjuvants. The Pharmacopœia Committee is awaiting definite information on these matters from the Government Departments immediately concerned. The Council may think it expedient to empower the Committee to act officially on its behalf in regard to the question, should the necessity arise.

In pursuance of a resolution of the Council of the Pharmaceutical Society of Great Britain, the Privy Council has issued an Order which places, in Part I. of the Poisons Schedule of the Pharmacy Act, 1889, emplastrum plumbi and like preparations of lead, whether sold as diachylon or otherwise. This Order will have the effect of restricting the sale of this poison for internal use, and so of diminishing a serious public danger.

Two Government measures now before Parliament include provisions which have recently formed the subject of representations by the Council. The Venereal Disease Bill, 1917, prohibits under penalties anyone not a registered medical practitioner from treating such diseases, and from prescribing or advising remedies therefor. It moreover prohibits all persons from offering by public advertisements or announcements to treat patients, or to prescribe, advise, or recommend medicines or preparations of any kind, in relation to venereal disease. The first prohibition will apply to any area within which an approved scheme for free treatment is in operation. The second will apply to the whole kingdom. The Criminal Law Amendment Bill, 1917, extends the Indecent Advertisements Act to non-professional announcements or advertisements, which suggest the use of drugs or appliances for specified purposes of an objectionable kind. The Council has long desired such reforms, and will welcome these enactments.

In response to an invitation from the Lord President of the Privy Council the Council has submitted to the Government a memorandum on the present state of the law respecting the practice of dentistry, both in this country and in the British Dominions.

In the Union of South Africa a measure is now before Parliament which is intended to have the effect of prohibiting altogether the unqualified practice of medicine, including dentistry, throughout the Union. As a federal University of South Africa has been established, possessing the power of conferrieg medical degrees, we may expect before long a request for the application to the Union of Part II. of the Medical Act, 1886. When reciprocity is thereby arranged with South Africa, another step, and that practically the last that remains, will have been taken towards the medical confederation of the Empire. Our allies Italy, Japan, and Belgium already stand in similar relations with this country: and it may be that the Council's next duty will be the endeavour to bring about some form of reciprocity with other allied and friendly nations, where the standards of medical education and qualification are not inferior to our own.

The Government has appointed a committee to inquire into the position of natural science in the educational system of Great Britain, especially in secondary schools and universities, and the President and the Chairman of the Students' Registration Committee were accordingly asked to give evidence. We attended on March 13th and furnished the committee with full information on the Council's functions and activities, together with statistics and estimates, based on facts within the Council's knowledge, concerning the present and prospective supply of medical and dental students and practitioners, and the provision for their instruction in pure and applied science. The relations between the professional curriculum and secondary education, both general and scientific, were naturally discussed with the committee. I explained that the Council had recently widened its regulations so as to admit of the recognition, for purposes of registration, of "Senior" Preliminary Examinations accepted for matriculation in the Faculties of Arts and Science; but that the content of the "Junior" Examinations, accepted from candidates for registration who had not completed a full course of secondary education of the "Senior" standard, was still to be settled by the Council. This question may come up for further consideration on a report from the Education Committee, and perhaps from the Dental Education and Examination Committee also. It is much to be wished that the result of the Government committee's recommendations may be the establishment in England of a system of school leaving certificates, based on well coördinated plans for secondary education applicable to the whole country. The Council has repeatedly expressed its sense of the need for the introduction of such a system. Apart from its obvious national advantages, it would go far to free the Council from the task of appraising a multitude of preliminary examinations in school subjects, which the existing want of system has forced us to undertake in the interest of professional efficiency.

The Finance Committee will be in a position to report that in 1916 the income of the several Councils exceeded their expenditure by over £1000. The surplus is, however, much less than that for 1915, and somewhat less than the average for the preceding seven years. It is not to be expected that it will recover its former level for some years to come. Meanwhile all accrued charges for our new building have been defrayed from the accumulations of past years, and all available balances have been invested in War Loan Stocks.

Owing to the incidence of Whit Monday on May 28th it will be highly inconvenient for the Council to sit beyond Saturday of this week. But I foresee no difficulty in completing by that day all that we have to do at this session.

Other Business.

It was formally intimated that medical reciprocity had been established with the Province of Manitoba.

The Council appointed its committees. The Executive Committee consists of Dr. Norman Moore, Dr. Taylor, Mr. Tomes, Dr. Langley Browne, Mr. Hodsdon, Dr. Norman Walker, Sir John Moore, and Sir Arthur Chance. The Penal Cases Committee is as follows: Mr. Tomes, Sir F. Champneys, Dr. Norman Walker, and Sir B. Windle.

Dr. F. Taylor was appointed junior treasurer.

The Council adjourned.

WEDNESDAY, MAY 23RD.

The Council was engaged during the whole sitting in considering complaints against medical practitioners.

LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.—The annual general meeting of the London and Counties Medical Protection Society, Limited, was held at the offices of the Society, 32, Craven-street, Strand, London, W.C., on May 16th. Colonel E. C. Bensley, who was in the chair, in proposing that the annual report and balance-sheet be received and adopted, delivered a short address reviewing the work of the society during the past year. He referred to the action taken by the society in supporting its members in difficulties which had arisen between them and the military authorities in regard to payment for examining recruits and to the work which had arisen through defects in the machinery of the National Health Insurance Act. The resolution adopting the annual report and balance-sheet was carried unanimously, with expressions of gratitude to the general secretary and the solicitors. It was unanimously resolved—

That as from Jan. 1st, 1917, at the end of each year payment should be made to any member of council—not a salaried official—residing more than four miles from Charing Cross, of first-class return railway fare, provided he has attended not less than half the meetings of the council or committees of council to which he has been summoned.

Colonel Sir John Rose Bradford, the President of the society, the treasurers, secretaries, and auditors were all re-elected.

DIFFICULTIES IN THE ADMINISTRATIVE CONTROL OF TUBERCULOSIS.

BY JOHN GUY, M.D. GLASG., M.R.C.P. EDIN., D.P.H. CAMB.,
ASSISTANT MEDICAL OFFICER OF HEALTH AND TUBERCULOSIS OFFICER, EDINBURGH.

IN the departmental (Astor) report on tuberculosis some of the most perplexing problems connected with this disease are handled with a delightful simplicity. Early cases are to be cured in the sanatorium. Working capacity is to be regained at a colony. Advanced cases are to be segregated in a hospital, and for the sake of completeness it might be added, the dead are to be buried in a cemetery.

Wholehearted attempts to deal with this disease on the lines indicated in the report soon reveal the fact that there are profound problems connected with this disease which are not easily solved, and, indeed, some appear at present almost insoluble.

From the clinical standpoint cases of tuberculosis are classified into three grades—early, intermediate, and advanced—but from an administrative point of view they might be classified as non-infectious and infectious. In such a classification the basal idea is the safety or otherwise of the community, but the patient himself is not necessarily thereby lost sight of. The aim of the administration should be to prevent the non-infectious from sinking to the ranks of the infectious, and, if possible, to make the infectious non-infectious, or at least render them harmless to the community.

The Non-infectious Class of Cases.

The non-infectious cases are divisible into three very distinct classes: (*a*) Early cases where the tuberculous process has not advanced to the breaking-down stage; (*b*) cases where the tuberculous lesion is old and is in a healed or cicatricial condition; and (*c*) cases where a cicatricial lesion exists complicated by the presence of some other pulmonary disease, such as bronchitis, emphysema, silicosis, &c.

It is not always easy to distinguish clinically between these separate sets of cases, and it is too commonly assumed if a lesion be detected in a lung that it is a commencing one requiring active treatment. Patients with cicatricial lesions in their lungs are excellent cases for sanatorium or other form of treatment, and they do almost as well as those assumed cases of pulmonary tuberculosis where, in fact, no lung lesion exists.

When the pulmonary condition is reckoned to be of recent origin the best form of treatment is undoubtedly a residence in a good sanatorium, although many do equally well in their own homes. In the majority of instances perfect recovery may be expected. Occasionally, however, cases occur where the disease progresses in spite of all treatment, and passes on through the infectious stage to a fatal termination.

The difficulties, clinical and administrative, are great where these cicatricial lesions are complicated by the presence of other pulmonary diseases, such as bronchitis, &c., and these cases are very numerous; unfortunately, there is always a demand for sanatorium treatment for them. The medical attendants are glad to get rid of these cases for a time, and the patients and their friends are anxious to try anything that gives promise of relief. While it must be admitted that in some of them there is marked improvement by a residence in a sanatorium, on discharge they soon fall back into their old condition. The only method of dealing with them is to admit them to the sanatorium for a short period of observation and determine the cause of the illness. If it be found that this is due to bronchitis, &c., and that the tuberculous focus is inactive, then the patient should be discharged as not suffering from tuberculosis.

The administrative procedure is clear when the curable cases are under consideration. They should be kept in a sanatorium until cured. The carrying out of this prescription is not, however, quite so simple as it appears. In the first place, the patients, after a term of residence, often feel so well that they insist on returning to work before a cure is complete, and nothing but force will detain them. If compelled to remain against their will, they mope and are discontented, and further progress toward recovery is extremely unlikely. In the second place, family considerations compel many to return to work too early. When a breadwinner is laid aside the family income is often hopelessly insufficient and the wage-earner is compelled to return to work prematurely in order to satisfy the clamant need of the family. In the third place, when the mother is ill difficulties equally great present themselves. The children often cannot be cared for satisfactorily in her absence, and the mother insists on returning home to her duties long before she is able to do so. The problem here at present is often quite insoluble and the mother returns to her work until utterly unable to perform it.

How the Administrative Difficulties may be Met.

Here, then, are three separate administrative difficulties which have to be faced. If the patient is curable then he ought to be cured, and this must be kept prominently in view when attempting to solve the various problems. When the patient wishes to return home because he feels so well that he assumes he is cured, in the great majority of instances he can be persuaded to spend the requisite time by the sanatorium superintendent. Compulsory retention is quite useless, and a wise and tactful superintendent can usually accomplish the desired end by personally dealing with the patient. When a breadwinner is laid aside and is compelled to return prematurely to work the only satisfactory solution appears to be that the family should receive a special sickness grant so as to ensure that the income is made equal to what it would be if the wage-earner were working. What chance of recovery has any patient who is continually haunted by the knowledge that the family at home are bordering on starvation and may only be kept alive by getting into debt as far as possible?

There would appear to be four probable sources from which money might be granted to make up the deficiency in the family income. 1. From philanthropic agencies. These are quite inadequate as a rule, and many agencies exclude tuberculous patients from benefit owing to the chronicity of the disease, 2. From the Poor-law. While in many cases doubtless the Poor-law authorities deal generously with the sick poor, as a rule the tendency is not toward generosity. Again, there is still a healthy prejudice in the minds of most working men against accepting Poor-law relief, so that on the whole it is neither likely nor desirable that the income should be augmented from Poor-law sources. 3. From a special municipal fund. Unfortunately no special fund for this purpose is in existence, nor, in view of present economic conditions, is one likely to be created. Still, it appears desirable that there should be such a fund, as the money spent in half-curing a patient is so much money wasted if he has to leave the sanatorium owing to financial difficulties at home. 4. From the National Insurance funds. For insured persons—and these constitute the bulk of male patients—it would appear equitable that an extra money grant should be given from Insurance funds to meet their financial strain while undergoing treatment. It is a recognised fact that the insured person in the matter of tuberculosis is doubly taxed. He is taxed as an insured person for sanatorium benefit and he is taxed as a ratepayer to keep up the city sanatorium. Such an anomalous condition ought to cease and institutional treatment should be provided by the local authority alone. The funds then in possession of the Insurance Committee for tuberculosis could be made available for other purposes, one of which might be the augmenting of the family income while the wage-earner was undergoing treatment.

When the mother of a family suffers from tuberculosis problems arise which are at present wellnigh insoluble. Speaking generally, mothers do not seek advice until the disease is well marked and the prospect of cure very much lessened. If the mother has a young baby at home it is very seldom that she will consent to a prolonged separation from her child. When there are several young children it is often a difficult matter to make provision for them while the mother is in the sanatorium, and the knowledge that the children are not properly cared for causes her much anxiety. In Edinburgh an attempt is made to meet this difficulty through assistance granted by the Royal Victoria Hospital Trust. In some cases the children are sent to different relatives; in others they are boarded out in a country home; but it is felt that this is a

duty which might properly devolve upon the local authority. This might be done by the municipality itself providing a temporary home, or by entering into an agreement with some other voluntary body to provide one. Suitable arrangements would be made for the father to contribute towards the maintenance of the children.

The Infectious Class of Cases.

The second class of patients—namely, the infectious—presents many intricate administrative difficulties. For clearness of argument they may be divided into three classes: (1) Where there is a likelihood of cure; (2) where the disease is advancing and a fatal termination may be expected in a few months; and (3) where the disease is practically stationary and an indefinite period of infectious life, probably of many years' duration, may be looked for.

In those cases where a cure may be looked for, sanatorium treatment, if deemed necessary, should be enforced. The chief difficulties in this class have already been discussed. In the patients with advancing disease the bedfast stage soon comes. In the poorer homes where accommodation is scanty removal to the hospital is often asked for, and in Edinburgh is always provided. At other times a mild compulsion is applied and the patient removed. In many cases, however, the relatives insist on the patient being left at home to die. Such an attitude is quite understandable, although not desirable from an administrative point of view. The best that can be said is that the period of risk to the others in the family is of comparatively short duration. Such cases should be dealt with on their individual merits, and compulsory removal should be effected where the home conditions are bad.

The greatest difficulty is presented by the chronic consumptive who lives for years and yet is in an infectious condition all the time. There is no possibility of curing him, so prolonged institutional treatment is out of the question. Compulsory segregation for this class, assuming it could be carried out, would mean a prison with a barbed-wire fence all round to preclude possibility of escape. It would also mean that any individual suspecting that he had consumption would avoid all medical aid until dying.

If the chronic consumptive cannot be cured, can he be educated so as to diminish the risk to others? This depends on the patient and on the sanatorium where he undergoes a short course of education. Even with the best training the ultimate conduct of the average working-class patients leaves much to be desired. Many of them, to their credit be it said, do their utmost to carry out the principles taught. Unfortunately, some sanatoriums teach nothing.

What, then, can be done with these chronic cases? If capable of work they should be encouraged to do what they can if thereby they are not a danger to others. If, however, the other workers object to have a tuberculous individual working in the same room, what then? Here is an actual case. A high-class dressmaker contracts tuberculosis and the disease, in spite of treatment, is progressing. She is still capable of some amount of work, but the work-girls object to her presence. She cannot now turn to any other form of occupation, nor is it desirable that she should continue dressmaking. She is in receipt of 5*s*. per week as disablement benefit, but this is insufficient for her needs. Surely, it seems desirable that this individual in her last year or two of life should be shielded from the twin curses of illness and poverty. We cannot now prevent the illness, but it appears to me that some measures should be taken to alleviate the poverty. If for the safety of the community a patient be excluded from his usual work, then the community should provide other suitable work or compensate such patient. This appears the only logical outcome. The compensation in the case of insured persons should come from the National Insurance funds.

The protection of the other members of the family forms a serious problem. Compulsory segregation not being attainable, a voluntary segregation might be successful if the rules of the institution could be so relaxed that the patient might be permitted a few hours off every afternoon or every alternate afternoon to visit his family. This would lessen the risk to the family considerably, although it would not abolish it altogether. There is much to be said both for and against such partial segregation, but it appears to merit a trial.

In other instances a measure of protection might be given by removing the family to a larger and better situated house. Here the patient might have a room set apart for his sole use, and by frequent visits of the tuberculosis nurse a certain standard of ventilation and cleanliness could be insisted on. The municipality in such cases should provide the better house, and pay, or assist in payment of, removal expenses. The segregation in such cases would be incomplete, but the healthier environment would act in increasing the resistance to the disease through improved health.

The whole question of segregation bristles with difficulties, and there is a grave possibility that at present too much attention is given to the germ and too little to the conditions which assist its growth and spread. The suggestion of the municipality providing better accommodation should be seriously entertained, and in the end it would probably save much hospital expense.

Summing up in conclusion, the curable should be sent to a sanatorium and moral suasion used to persuade them to remain until cured. In order to enable this being done the family income should be supplemented where necessary. In the case of a mother being ill the municipality in some instances should be prepared to care for the children during her illness. In the case of patients with advanced and progressing disease some should be compulsorily segregated and others provided with a separate room. The most difficult cases are the chronic ambulant infectious patients. With them voluntary segregation might be tried, with some modification of the sanatorium or hospital routine. Larger and better housing might be provided, with closer supervision and greater cleanliness and ventilation. The local authority should provide the institutional treatment, and the Insurance Committee should dispense its funds as a special tuberculous disablement benefit. In a city like Edinburgh this would mean that a sum approximating £3000 per annum would be available for special grants in necessitous tuberculous cases.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM: ANNUAL CONGRESS.

(*Concluded from p. 771.*)

THE proceedings of the Congress on Thursday afternoon, May 3rd, took the form of a visit to St. Dunstan's, Regent's Park, where the various activities and methods of training in operation were inspected, under the direction of Sir Arthur Pearson, Bart.

Visit to St. Dunstan's and a Discussion on the Employment of the Blind.

Sir ARTHUR PEARSON said St. Dunstan's had set an entirely new pace in the blind world. It was very important to try to abolish from the minds of the afflicted men morbid thoughts on their own condition; it not only resulted in greater happiness for them, but enabled the men to make the best use of their faculties by concentrating on the work in hand with a view to earning their independence. Very great assistance in the training was derived from the employment of blind pupil-teachers, for they were able to bring to the work the standpoint of one similarly afflicted. Owing to the intense application involved in the training the actual work was not allowed to extend beyond two and a half hours in the morning and a like period in the afternoon. The men were taught not only how to work, but also how to play, and rowing on the lake, horse-riding, and other forms of recreation were freely indulged in. He had received very high praise of the work done by the skilled blind masseurs who were fully trained and certificated in the institution, and the shorthand and typewriting abilities of many were good enough to command salaries up to the usual standard. Men whose work had been of a special supervising and advisory nature had been able to resume this work in their former posts with credit. Sir Arthur Pearson concluded with some remarks on the highly developed sense of proximity among blinded people. He attributed this to three factors—echo, difference in air pressure, and difference in temperature, which became apparent to the alert senses remaining.

Mr. ARNOLD LAWSON said that before the war very few agencies attempted the systematic training of the blind in all its aspects: there was a good deal of overlapping and much inefficiency. The crowd of young blinded men who had now been thrown on their country raised the question of the training of the blind to one of national importance.

The brilliant initiative of Sir Arthur Pearson had as the basis of its success the centralisation of effort, so that St. Dunstan's had become a centre where all aspects of training—moral, social, and economic—were fostered and encouraged. Those who set out to train the blind must be themselves trained. Here the blind man was taught how to live as a blind man, to be encouraged and supported in his initial difficulties by the companionship and experiences of others similarly placed. There was no fixed limit of tuition; the blind man had come to be trained, and he was kept until that had been accomplished, so that he was turned out as an active and independent citizen. A very important corollary was the after-care department, which followed up and looked after the blinded man when he sought to occupy a place in the world. This was necessary because in a blind man's work mistakes crept in which, not having been seen, remained uncorrected, wrong work thus becoming a habit, and the quality of the work deteriorating. He also needed protection in the buying of materials and against the designs of unscrupulous persons. He advocated marriage for the blinded young man; to a peculiar degree he needed someone to give him sympathetic care and to keep him neat and tidy, but every care should be taken to safeguard him from being exploited by unsuitable women. Mr. Lawson believed that this organisation, brought into being by the war, would prove a blessing in the future to ordinary cases of blindness arising in civil life.

Mr. H. B. GRIMSDALE discussed the question from the standpoint of his experiences the Normal College for the Blind. He pointed out that the handicap of blindness was at its greatest in the case of the craftsman and much lessened in the professional man, whose brain was as keen and efficient as when he could see, and his memory more highly trained. Sir Arthur Pearson's memory, for instance, though always good, was now prodigious. He emphasised the point that no one employment was good for all blinded persons. Hence it was a mistake to concentrate on one kind. There would always be a certain number of civilians of middle age blinded at their work, but the really important matter was to see that every blind child had his chance. He proceeded to detail the work done at the Normal College and some of the characteristic results obtained.

The discussion was continued by Captain A. W. ORMOND, Captain CRUISE, and the PRESIDENT. Sir ARTHUR PEARSON replied.

Clinical Meetings and Discussions.

Friday morning was devoted to visits to witness operations at the Royal London Ophthalmic Hospital, the Royal Eye Hospital, Southwark, and the 2nd London General Hospital, Chelsea, and the afternoon was occupied by a clinical meeting at the Royal London Ophthalmic Hospital, at which a very large number of cases were exhibited and discussed.

On Friday evening the following papers were read and discussed:—

Mr. W. B. INGLIS POLLOCK: Two cases of Leber's Disease (Hereditary Optic Atrophy), with X ray examination of the sella turcica.—The same subjcet was fully discussed by Mr. J. HERBERT FISHER.

Mr. G. MACKAY: A case of Uveo-parotitis with Irido-cycloplegia.

Mr. C. WORTH: Remarks upon Advancement Operations.

Mr. A. LAWSON: A case of Detachment of the Retina at the Ora Serrata.

Mr. E. CLARKE: Ophthalmometry in Estimating the Refraction of the Eye.

Mr. L. PATON: Spasm of Accommodation.

Lieutenant-Colonel R. H. ELLIOT: Operation of "Couching" of Cataract as Performed in India: its History, its Technique, and its Exponents.[1]

Mr. J. H. PARSONS: The Apocritic Principle and Visual Sensations.

On Saturday morning a discussion was held on

Concussion Injuries to the Visual Apparatus.

Captain A. W. ORMOND, in opening the debate, confined his attention to the subdivision contusio bulbi, leaving to others the consideration of contusio cerebri. His paper was based upon cases he had met with at the 2nd London General Hospital and at St. Dunstan's. The dictionary defined concussion as a condition induced by more or less violent shaking of some particular organ whereby serious symptoms might be induced, to account for which no definite lesion could be detected. But owing to the enormous power of modern explosives, violent shaking or concussion might lead to very definite lesions. The paper dealt with cases in which there had been injuries the result of vibrations conveyed from a distance. Violence transmitted through the bones of the skull was able to reach the inner tunics of the eye. Blows on the sides of the orbit could be transmitted through the sclerotic and produce serious concussion of the retina or choroid. And the part of the eyeball unprotected by bone might be influenced by air vibrations, many cases of serious damage to the globe having been recorded as due to "windage," in which, so far as could be ascertained, no solid particles struck the face. Vibration could so affect the outer surface of the eyeball, without disintegrating the dense sclerotic, as to pass through it with sufficient force to rupture the less firmly knit choroid and retina. In some cases the globe had been, in this way, entirely disorganised. Concussion or contusion effects could be produced in four different ways: (1) By vibrations the result of metal or other particles traversing the orbits; (2) by vibrations the result of blows on the bones of the orbit and face transmitted to the interior of the eyes; (3) by vibrations transmitted to the deeper parts of the globe through the corneo-scleral tunic without rupture of the eyeball; (4) by vibrations the result of windage. Captain Ormond then proceeded to deal in detail with the various structures of the globe as they had been affected by concussion injuries, and gave a tabulated list of cases to illustrate his remarks. With regard to treatment, he insisted on the extreme usefulness of the hot coil—i.e., a pad of lint or a bandage through which a graduated electric current is passed. In assuaging the pain of a bruise of the eye this, in the author's opinion, has no equal. His belief was still strong that mechanical means were best for hastening the absorption of vitreous or retinal hæmorrhage. He had not hesitated to deal with complete traumatic cataracts as soon as the eye had recovered from the immediate effects of the traumatism, and in only one case had he had cause to regret doing so. That single exception was one in which a piece of wood was present in the ciliary body, and a septic irido-cyclitis developed, which resulted in a shrunken fluid eye. In dealing with wounds which involved the air cavities flanking the orbits, free drainage was necessary. Hot fomentations frequently applied formed the best dressing for wounds about the orbits, which were almost invariably septic.

Dr. S. A. KINNIER WILSON, in a paper dealing with injuries of central origin, said the whole question of commotio was still shrouded in considerable obscurity, looseness of conception being responsible for some clinical confusion. In some of these cases which had proved fatal the closest investigation had not revealed recognisable anatomical lesion. In most instances of severe blow on the head there were capillary hæmorrhages, minute lacerations of the cerebral substance, and consequent disintegration of myelin. With the blow there had been a sudden dispersion of cerebro-spinal fluid, which tended to escape too abruptly by the natural exits. Complete recovery might ensue, even after severe symptoms. The term "cerebral contusion" was more applicable to cases in which recognisable organic changes had occurred, as it excluded mere "functional" disturbance. Oppenheim holds that the basis of "shock" is cerebral commotio. Fickler believes that the conception of concussion of the spinal cord, of purely molecular origin, is not admissible. The experiments of Alan Newton showed that there was an organic basis for the transient disturbances of function seen in so-called "railway spine" and allied conditions. There might be a surprising amount of tissue change from a feeble impact. The tremendous speed of projectiles in warfare rendered ordinary pure commotio almost impossible. Hence cases of pure visual concussion in the war were very few; he excluded cases in which there had been a shell explosion in the near vicinity. The case which approached most nearly to pure commotio among those he had seen was that of a soldier, aged 19, who was hit on the back of the head by a shell fragment while cutting wood in a dug-out. He lost consciousness for three minutes, reviving when his mate moved his right arm, which had also been hit and was very painful. He felt very sick, and was quite blind in both eyes, remaining blind for 40 to 48 hours. On the third day he was able to see dimly with each eye. There was no dysmetropsia. The same afternoon a small piece of bone was removed from the orbit, and a little later another piece. The shadowy objects which he saw at first had no colour, while shutting his eyes did not always banish the image. These subjective phenomena disappeared after about a fortnight. Two months later, the pupillary reactions and the optic discs were normal, vision 6/60 in both eyes, Jaeger 14 in both. There was a concentric diminution of both fields for white and colours, and marked visual fatigue. A skiagram showed that the outer table was splintered, and the inner one cracked. This certainly was not a case of traumatic hysteria; moreover, except for the visual symptoms, there was no impairment of function of the nervous system discoverable. Dr. Wilson's conclusion was that visual impairment after generalised commotio cerebri was far more rare than was labyrinthine or other auditory impairment.

[1] THE LANCET, 1917, i., 325. 361.

The PRESIDENT (Mr. E. Treacher Collins) contributed to the discussion with remarks on sub-choroidal hæmorrhage from concussion, and its relation to (*a*) "commotio retinæ"; (*b*) "holes at the macula"; (*c*) pigmentation of the retina; and (*d*) pigmentary disturbance at the macula. Subchoroidal hæmorrhage was, he said, a condition with which ophthalmic surgeons were most familiar when it occurred after intra-ocular operations, such as extraction of cataract or iridectomy for glaucoma. Probably in these cases the choroidal vessels were sclerosed and brittle, when, owing to diminution of intra-ocular pressure, the blood rushed in and expanded them. The pressure of the suffused blood forced the choroid inwards and the contents of the globe forwards towards the wound, from which, in many cases, some of it escaped. Indirect rupture of the globe also produces subchoroidal hæmorrhage, as might occur in the intact eyeball after concussion. In the latter case the blood effused tended to accumulate as a flattened layer rather than as a prominence, probably because it met with resistance from the sclerotic externally. Subchoroidal hæmorrhage must be differentiated from intrachoroidal hæmorrhage. The former was probably, he thought, due to rupture of the larger vessels in the outer layer, and the latter to an effusion from the capillary and inner layer. An effusion of blood external to the choroid would not be visible as such ophthalmoscopically. The obstruction to the choroidal circulation produced by subchoroidal hæmorrhage was not necessarily permanent; the effusion of blood causing it must cease as soon as it was produced. Berlin described the clinical appearances of an eye affected with commotio retinæ as considerable diminution in the acuity of vision in the centre of the field and marked resistance of the sphincter papillæ to the influence of atropine, followed shortly afterwards by distinct haziness of the fundus and possibly small hæmorrhages. The changes were most marked around the yellow spot. The highest development was reached in 24 to 36 hours, and it disappeared in two to three days. Sight much improved at first and then remained stationary. Haab found that of 167 cases of concussion of the eyeball 82·6 per cent. showed no alteration in the fundus. Mr. Collins believed Berlin's observations to be correct. He thought it still remained to be proved whether concussion injuries of the eye might result in extra-ocular rupture of a ciliary artery, but there was definite evidence that they might produce subchoroidal hæmorrhage. Following severe contusion of the eye there might be pigmentary disturbances of the macula, causing permanent impairment of vision.

Captain CRUISE, Sir GEORGE BERRY, Mr. A. L. WHITEHEAD, Dr. GEO. MACKAY, Dr. T. HARRISON BUTLER, Mr. A. B. CRIDLAND, and Mr. P. C. BARDSLEY continued the discussion, and Captain ORMOND replied.

An interesting addendum to the Congress took the form of a museum of drawings, pathological specimens, and ophthalmoscopes, which was under the charge of Mr. W. H. MCMULLEN who read a paper on the History of the Development of the Ophthalmoscope.

THE CONTROL OF VENEREAL DISEASES.

Phenol Serum in Gonorrhœa.

Dr. F. Guillermo Cano, professor of genito-urinary diseases in the Medical School of San Salvador, C.A., states that as the result of two years' laboratory work he has produced a definite chemico-biological substance, known as methyl-phenol serum, and that he has proved its efficacy and safety in the treatment of more than 3000 private and hospital patients. The results were published in the Archives of the Rosales Hospital, San Salvador, in 1910 and in November, 1913. Four years of clinical experience with this method have enabled him to summarise as follows:—

1. The treatment of gonorrhœa by intravenous injections of this serum until the disease has reached its declining stages prevents complications. 2. Pain, discomfort, and all other subjective and objective symptoms usually disappear after the fourth or fifth injection, and definite clinical and bacteriological cures are effected in from 30 to 40 days. 3. Ten injections are usually sufficient when the infection is attacked at its onset. 4. Gonorrhœa, when complicated by primary or secondary syphilis, successfully responds to the treatment if additional antisyphilitic medication is employed. 5. Local complications, such as epididymitis, buboes, abscesses, &c., together with systemic manifestations such as toxæmia and the paragonococcal lesions, disappear more rapidly with this form of treatment than with any other, and surgical interference is rarely necessary. 6. By the use of intravenous and intraprostatic injections of the serum months, not years, are required to cure chronic residual prostatic gonorrhœa and its numerous recrudescences.

It is claimed that an intravenous injection of 10 c.c. of methyl-phenol serum or an intraprostatic injection of normal phenol serum is non-toxic. A paper on the above treatment by Dr. F. G. Cano, Dr. Terry M. Townsend, and Dr. Julius J. Valentine, of New York, was read before the American Urological Association at its annual meeting in Chicago, Illinois, on April 2nd–4th last by Dr. Townsend. Dr. Townsend and Dr. Valentine have administered between six and seven hundred intravenous injections of methyl-phenol serum and 67 intraprostatic injections of normal phenol serum in 73 selected private and hospital patients. It is from the latter series of infections covering a period of almost one year that they have made their clinical observations and deductions. Their conclusions are as follows:—

1. Methyl-phenol serum may be injected repeatedly intravenously in doses of 10 c.c. into adults at intervals of 48 hours without danger or detriment to life or health. 2. Its use has a tendency to prevent complications by killing or rendering inert the invading gonococcus at the site of residence. 3. For the same reason and because of the neutralisation of gonotoxins it shortens the course of the gonorrhœa and alters a vicious into a benign infection. 4. Its use causes general increased economic resistance, hence gonorrhœal sequelæ are rare. 5. Intraprostatic injections of normal phenol serum are harmless when correctly performed, frequently cause a rapid disappearance of gonococci from the prostatic secretion, and invariably shorten the time required to cure chronic gonorrhœal prostatitis. 6. The treatment of gonorrhœa by the application of Cano's theory of intravenous injections of methyl-phenol serum and intraprostatic injections of normal phenol serum is firmly based upon chemico-biological facts and accepted authoritative theories, and bears the same relation to gonorrhœa that intravenous injections of arsenical preparations bear to syphilis. 7. This is the first application of the immutable laws of chemico-biology to gonorrhœal infection, and forms the basis for a scientific and uniform treatment of gonorrhœa.

According to Dr. Cano, the rôle of either an intravenous injection of methyl-phenol serum or an intraprostatic injection of normal phenol serum is that of an antiseptic, and its effects are due to the action of phenol on the gonococcus and its toxins at the site of infection, locally, and within the body, systematically by means of the blood stream. It is to be sincerely hoped that further results, or a more widespread use of this mode of treatment, may substantiate the claims made for its efficacy by the authors of the paper.

A Syphilis Number of the "Indian Medical Gazette."

The *Indian Medical Gazette* for April, 1917, contains a special supplement of 34 pages, with four essays on Recent Advances in the Treatment of Syphilis, the result of a recent competition. Lieutenant-Colonel J. T. Calvert, I.M.S., principal of the Calcutta Medical College, and Lieutenant-Colonel W. D. Sutherland, I.M.S., imperial serologist, acted as judges, awarding the prize to Dr. Rajendra Kumar Sen, of the Dejvo Tea Company, Lakhimpore, North Assam. The other three essays published are by Lieutenant-Colonel E. E. Waters, I.M.S., Captain T. Crawford Boyd, I.M.S., and Saret Chandra Ghose, L.M.S. While not adding anything new to the subject of syphilology, the four papers form a summary of recent work which cannot fail to be of use for reference to other workers.

Enlightenment Campaign.

Mr. N. Bishop Harman has written a little book, entitled "Staying the Plague" (Methuen's Health Series. 1917. Pp. 120. Price 1*s.* net), in which he sets forth in clear language and with striking illustration the main facts of sex, of venereal disease, and of the means of preventing such disease. The book is intended to help in widening the awakening due to the report of the Royal Commission into an intelligent and progressive activity, and is, we think, well fitted to this end. The medical reader will find material usefully arranged for teaching purposes. Kipling's paraphrase, "The fathers have eaten of forbidden fruit and the children's teeth are notched," will be fresh to many.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Nursing Board for Ireland.

THE Nursing Board for Ireland, established by the Royal College of Surgeons in Ireland, has held its first meeting under the presidency of the President of the Royal College of Surgeons, Lieutenant-Colonel William Taylor, who has been elected chairman of the Board. The College has nominated four members of the Board—Lieutenant-Colonel W. Taylor, Lieutenant-Colonel Sir Arthur Chance, the Right Hon. Dr. Michael F. Cox, and Dr. T. P. C. Kirkpatrick, and with them are 22 nurses elected by representatives of the nursing profession. A committee was appointed to draft by-laws.

Tuberculosis in Co. Tyrone.

At a meeting of the Tyrone Insurance Committee held on May 12th Dr. E. C. Thompson, surgeon to the Omagh County Infirmary, criticised severely the treatment of tuberculosis patients in the county of Tyrone. He pointed out that though a large amount of money was being spent there was no report issued to give the public an opportunity of judging whether they were getting value for it. As an expert, expressing the opinion of experts, he could say they were practically getting no value, and that, he averred, was the opinion of nearly every doctor in the county. Criticising the constitution of the County Council Tuberculosis Committee, he said every expert in the county had been left out with the exception of their own official. He was not casting any reflection on their tuberculosis medical officer, but the whole system was wrong, and the only way to treat the disease was to get at the root of it. There should be better housing, inspection of school children, and an attempt made to stop the ravages of drink. There can be no doubt that in Ireland the means for dealing with tuberculosis are producing no results, as is clear from the fact that the mortality for tuberculous disease per 1000 in 1915 was 2·20, which is 0·13 above that for 1914, and 0·03 above the average rate for the period 1910–14. In England and Wales in 1915 the rate was 1·5. The statistics for 1916 are not yet published.

An Inquiry at Portrane Asylum.

The Inspectors in Lunacy recently held an inquiry into the circumstances surrounding the death of a patient in the Portrane Auxiliary to the Richmond Asylum. From the evidence given it was established that when one of the assistant medical officers was summoned in the middle of the night to attend the patient, he declared that he was off duty and referred the messenger to his colleague. The latter also said that he was off duty, and although the two medical men met and engaged in some controversy neither visited the patient, who died an hour later. The inspectors comment strongly on the refusal of both medical officers to attend in reply to an urgent message, and on their standing on their supposed rights. Their conduct was, the inspectors said, alien to the traditions of the medical profession. At the next meeting of the Richmond Asylum committee both officers were called on to resign.

May 22nd.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

To be temporary Surgeon: E. Bayley.

ROYAL ARMY MEDICAL CORPS.

To be temporary Lieutenant-Colonels: E. H. Taylor and A. R. Parsons.

To be acting Lieutenant-Colonels while in command of a Casualty Clearing Station: Major A. M. MacLaughlin and Brevet-Lieut.-Col. A. H. Safford.

To be acting Lieutenant-Colonel whilst in command of a Stationary Hospital: Capt. (temp. Major) J. A. Manifold.

To be acting Lieutenant-Colonel while in command of a Field Ambulance: Capt. Francis W. M. Cunningham.

Major Raymond L. V. Foster and Temp. Capt. J. G. Johnston relinquish the acting rank of Lieutenant-Colonel on re-posting.

To be temporary Majors: Temp. Capts. C. S. Read, S. W. Woollett, and E. A. Chartres, and J. C. Briscoe, W. A. Winter, R. C. B. Maunsell, and K. E. L. G. Gunn.

To be temporary Captains: F. W. H. Hutchinson, L. A. Walker, F. Fraser, R. B. Taylor, Temp. Lieut. E. W. Honsinger (Canadian Army Dental Corps), E. C. Black, W. C. Mayo, G. D. Laing, Lieut. D. H. Coats, W. Boxwell, C. E. Boyce, F. H. McC. Crawley, and E. J. M. Watson.

To be temporary Captains while employed at the Belfast Orthopædic Hospital: S. T. Irwin and C. G. Lowry.

To be temporary Lieutenants: E. J. Peill, P. C. Leslie, G. H. U. Corbett, W. R. Reeds, H. A. Richards, A. Fraser, J. H. Ashworth, B. V. Ward, D. M. Humby, J. Blakely, J. H. Clatworthy, J. H. Porter, A. Roemmele, R. W. Brown, J. J. S. Scrase, W. St. J. Cogan, H. C. Malleson, H. M. Thompson, J. Wells, H. Cox, J. B. Anderson, R. F. Lunn, W. R. Read, W. Kingdon, F. G. Power, C. Gordon, S. H. S. Taylor, H. F. Lumsden, J. W. Miller, F. E. Larkins, M. Stewart, H. A. Edwards, F. H. Kitson, J. S. Crichton, F. Anderson, D. McDougall, F. R. L. Atkins, J. I. Greig, E. H. Smith, M. Macleod, G. Burnet, S. H. Robinson, R. Larkin, J. Campbell, A. H. G. MacKintosh, H. A. Evans, H. G. Arnott, L. L. Winterbotham, W. B. Griffin, W. Messer, J. Jenkins, E. Thorp, W. S. Alderson, T. S. Sharpley, F. M. Longson, J. S. Soulter, A. Chance, E. G. Stanley, C. G. McAdam, K. G. Colquhoun, J. S. E. Selby, G. C. McL. Barber, P. J. D. O'Malley, A. C. Reid, C. H. Wilson, J. T. Daly, J. E. MacFarlane, R. W. H. Hillis, H. N. Marrett, W. H. Pallett, P. A. Wedgwood, P. M. Reid, W. Fleming, D. Higgins, W. D. Ross, P. de S. Smith, A. J. M. Paget, W. A. Watson, S. C. Jellicoe, S. B. Depree, W. H. Roache, P. A. Mitchell, O. Marshall, H. MacKenzie, C. Alison, G. Maxted, P. R. Chevreau, T. Craig, K. D. Marriner, E. Lewis, R. W. Eddie, R. G. Williams, F. I. Dawson, R. H. G. Oulton, A. H. Southam, A. H. Holmes, J. W. Johnstone, E. E. Willis, B. J. O'Donnell, J. B. O'Reilly, G. Birch, R. H. S. Torney, F. G. Smyth, R. W. Reid, A. S. Rose, W. Martin, F. Brickwell, A. C. Campbell, A. G. Wilson, H. Leach, F. C. Trapnell, W. Waugh, C. Elliott, W. J. Lord, T. C. Innes, W. L. Stuart, N. Beattie, D. Mackinnon, J. Buchanan, W. T. Lydall, J. S. W. Nuttall, W. Chapman, A. P. Nicolle, E. A. Bullmore, H. R. Crisp, E. G. von B. Bergh, R. Buchanan, W. H. Woodyer, H. J. Henderson, A. C. Wilson, H. R. Carter, H. G. Barrie, R. S. Topham, T. W. Lonsdale, L. C. W. Cane, F. M. Bishop, A. J. Turner, R. C. Muir, J. W. Power, F. MacK. Matheson, H. D. Ledward, W. St. C. McClure, W. A. Sharpin, O. W. Jones, H. R. Elliott, G. P. Humphry, S. M. MacKenzie, A. N. Hodges, R. A. McCrea, E. L. Jones, R. F. Ballantyne, F. R. Carroll, G. McQ. Brunton, D. M. Cox, M. Horan, J. Owen, A. B. Scott, W. Smith, S. S. Brook, E. A. Edington, C. E. A. Goddard.

Officers relinquishing their commissions: Temp. Major R. H. Crosse, Temp. Capts. (on account of ill-health) T. Mulcahy and W. V. T. Styles, Temp. Lieut. T. A. MacKenzie.

SPECIAL RESERVE OF OFFICERS.

To be Lieutenants: C. V. Pearson, P. B. Pinkerton, and A. J. B. Griffin (from Manchester University Contingent O.T.C.); J. D. Johnson (from Durham University Contingent O.T.C.); J. Allison, J. B. Hanna, W. McElroy, R. B. Smith, J. Aitken, J. L. Hill, J. M. Martin, J. H. Neill, F. J. Jack, and H. Patlansky (from Edinburgh University Contingent O.T.C.); F. W. Hebblethwaite, H. F. Hollis, C. L. Somerville, J. W. W. Baillie, A. McA. Blackwood, J. MacD. Clark, A. Dick, J. R. R. Holms, W. H. Kerr, J. Liddell, F. C. Logan, K. McAlpine, A. D. C. McGowan, D. W. M. MacKenzie, W. D. Miller, W. H. Palmer, J. W. Patterson, H. B. Sergeant, A. W. Smith, and R. Wiggins (from Glasgow University Contingent O.T.C.); R. R. Garden, A. C. Irvine, W. W. Nicol, and R. Thom (from Aberdeen University Contingent O.T.C.); J. H. Davison (from Queen's University, Belfast, Contingent O.T.C.); H. W. Lewis, J. E. Carpenter, E. B. Andreae, A. G. E. Wilcox, H. J. C. Churchill, E. D. Spackman, A. O. Bolton, and W. J. FitzG. Powell (from University of London Contingent O.T.C.); R. Nixon, E. Bramley, J. M. Morrison, L. C. Rudd, D. Lennox, E. S. Stubbs, C. Shearer, T. G. Roche, and W. C. MacKinnon (from Unattached List, T.F.), and H. W. Featherstone.

Lieutenant (on probation) F. M. Rorie is confirmed in his rank.

TERRITORIAL FORCE.

Lieut.-Col. J. F. Dobson, from temporary retired pay list, to be Lieutenant-Colonel, with precedence as from October, 1914.

Lieutenants to be Captains: S. F. H. Everill, G. Thomson, A. G. Banks, and A. E. Raine.

Major J. R. Williams relinquishes his commission on account of ill-health.

Capt. (temp. Major) J. Innes relinquishes his commission on account of ill-health, and is granted the honorary rank of Major.

URBAN VITAL STATISTICS.

(Week ended May 19th, 1917.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 17,000,000 persons, the annual rate of mortality was 14 4, against rates declining from 18·5 to 15·3 per 1000 in the five preceding weeks. In London, with a population exceeding 4,000,000 persons, the death-rate was 13·9, or 1·5 per 1000 below that recorded in the previous week; among the remaining towns the rates ranged from 5·9 in Smethwick, 6·3 in Acton, and 7·1 in Hornsey, to 26·2 in Carlisle, 26·3 in Great Yarmouth, and 26·6 in Middlesbrough. The principal epidemic diseases caused 377 deaths, which corresponded to an annual rate of 1·2 per 1000, and included 204 from measles, 61 from whooping-cough, 59 from infantile diarrhœa, 35 from diphtheria, 10 from enteric fever, and 8 from scarlet fever. The deaths from measles were 48 fewer than the number in the previous week, and caused the highest annual death-rates of 2·5 in Bolton, 3·1 in West Bromwich, 3·3 in Rotherham, 3·8 in South Shields, and 4·1 in Middlesbrough. The 673 cases of scarlet fever and 1160 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 34 and 19 below the numbers remaining at the end of the previous week. Of the 4669 deaths from all causes in the 96 towns, 155 resulted from violence. The causes of 38 deaths were uncertified, of which 6 were registered in Birmingham, 5 each in Liverpool and Manchester, and 4 each in St. Helens and Carlisle, but only 1 in London.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual death-rate was equal to 17·0, against rates declining from 18·4 to 15·9 per 1000 in the three preceding weeks. The 393 deaths in Glasgow corresponded to an annual rate of 18·4 per 1000, and included 42 from measles, 33 from whooping-cough, 4 each from diphtheria and

* Including membranous croup.

infantile diarrhœa, and 2 from scarlet fever. The 107 deaths in Edinburgh were equal to an annual rate of 16·8 per 1000, and included 15 from measles, 6 from whooping-cough, and 1 from diphtheria.

Irish Towns.—The 141 deaths recorded in Dublin were equal to a rate of 18·4, or 1·9 per 1000 below that recorded in the previous week, and included 3 each from whooping-cough and infantile diarrhœa, and 1 each from measles, scarlet fever. and diphtheria. The 141 deaths in Belfast corresponded to an annual rate of 18·7 per 1000, and included 2 from enteric fever.

VITAL STATISTICS OF LONDON DURING APRIL, 1917.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 3·7 per 1000 of the population, estimated at 4,237,387 persons in the middle of the year; in the three preceding months the rates were 4·0, 4·2, and 4·4 per 1000 respectively. The lowest rates last month were recorded in Paddington, Kensington, Chelsea, the City of Westminster, the City of London, and Battersea; and the highest rates in Stoke Newington, Finsbury, Shoreditch, Poplar, Southwark, and Bermondsey. The prevalence of scarlet fever showed a considerable decline last month; among the several metropolitan boroughs this disease was proportionally most prevalent in Finsbury, Shoreditch, Bethnal Green, Southwark, and Bermondsey. The Metropolitan Asylums Hospitals contained 712 scarlet fever patients at the end of last month, against 800, 811, and 785 at the end of the three preceding months; the weekly admissions averaged 93, against 111 and 102 in the two preceding months. Diphtheria also was less prevalent than it had been in other recent months; the greatest proportional prevalence of this disease last month was recorded in St. Marylebone, Hampstead, St. Pancras, Stoke Newington, Holborn, Finsbury, Shoreditch, Stepney, Poplar, Bermondsey, and Lambeth. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1420, 1453, and 1367 at the end of the three preceding months, had further declined to 1206 at the end of last month; the weekly admissions averaged 142, against 168, 165, and 161 in the three preceding months. Enteric fever was rather less prevalent than in either of the two preceding months; the 30 cases notified during the month included 8 in Camberwell, 3 in Kensington, 3 in Poplar, and 2 each in St. Pancras, Islington, and Shoreditch. There were 25 cases of enteric fever under treatment in the Metropolitan Asylums Hospitals at the end of the month, against 29 at the end of each of the two preceding months; the weekly admissions averaged 4, against 4 and 6 in the two preceding months. Erysipelas was proportionally most prevalent in Stoke Newington, Shoreditch, Poplar, Southwark, and Bermondsey. The 46 cases of cerebro-spinal meningitis included 7 in Islington, 5 in Fulham, 5 in St. Pancras, and 4 in Battersea; and a case of poliomyelitis was notified in Lewisham. The 17 cases of puerperal fever notified during the month included 4 in Wandsworth, 2 in the City of Westminster, and 2 in Poplar.

The mortality statistics relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ending April 28th the deaths of 5902 London residents were registered, equal to an annual rate of 18·2 per 1000; in the three preceding months the rates were 18·4, 21·3, and 18·3 per 1000 respectively. The lowest rates last month were 13·0 in the City of London, 14·6 in Lewisham, 15·1 in Hammersmith, 15·4 in Hampstead and in Woolwich, and 15·7 in Stoke Newington and in Stepney; the highest rates were 20·9 in Kensington, 21·1 in Southwark, 21·2 in Holborn, 21·3 in Paddington, 21·6 in St. Marylebone, 21·7 in Shoreditch, and 22·3 in St. Pancras. The 5902 deaths from all causes included 510 which were referred to the principal infectious diseases; of these, 337 resulted from measles, 10 from scarlet fever, 49 from diphtheria, 44 from whooping-cough, 9 from enteric fever, and 61 from diarrhœa and enteritis among children under 2 years of age. The lowest death-rates from these diseases were recorded last month in Chelsea, the City of Westminster, Hampstead, Hackney, and Shoreditch; and the highest rates in Paddington, Fulham, St. Marylebone, Holborn, Poplar, and Camberwell. The 337 deaths from measles were 130 in excess of the average number in the corresponding period of the five preceding years; this disease was proportionally most fatal last month in Paddington, Kensington, Fulham, St. Marylebone, Holborn, Finsbury, Poplar, Bermondsey, Wandsworth, and Camberwell. The 10 deaths from scarlet fever were only one-half of the corrected average number, and included 2 in Southwark. The 49 deaths from diphtheria were 8 in excess of the average, and included 6 in St. Pancras, 6 in Camberwell, 4 in Fulham, 4 in Hackney, 3 in Southwark, and 3 in Wandsworth. The 44 fatal cases of whooping-cough were 85 below the corrected average number, and included 9 in Lambeth, 8 in Camberwell, 7 in Wandsworth, 4 in Southwark, and 3 in Islington. The 9 fatal cases of enteric fever were 4 in excess of the corrected average, and included 2 in Southwark. The 61 deaths from diarrhœa and enteritis among children under 2 years of age showed a decline of 2 from the average number; the greatest proportional mortality from this cause was recorded in Hammersmith, Fulham, St. Pancras, Holborn, Stepney, and Poplar. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was 9·7 per cent. above the average.

THE LATE SIR HUGH LANE'S MAGNIFICENT RED CROSS GIFT.—It will be remembered that the late Sir Hugh Lane, who was drowned in the sinking of the *Lusitania*, bid £10,000 at the first Red Cross sale in 1915 for a portrait to be painted by Mr. Sargeant. The executors of Sir Hugh Lane have now forwarded a cheque for the amount stated, but the sitter for the painting has not been nominated.

The War.

THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue :—

Accidentally Killed.

Capt. J. F. St. J. Annesley, R.A.M.C., was educated at Queen's College, Belfast, and qualified in 1888. He was in practice in Ireland before joining the R.A.M.C., and met his death through an accident to an aeroplane in which he was endeavouring to experience the effects of flying on the nerves.

Died of Wounds.

Capt. P. H. Burton, R.A.M.C., attached London Regt., was a student at the London Hospital and qualified in 1914.

Wounded.

Capt. C. A. R. Gatley, R.A.M.C., attached the Buffs.
Capt. D. J. S. Stephen, M.C., R.A.M.C.
Capt. R. B. Wallace, R.A.M.C., attached Leicester Regt.
Capt. H. G. Willis, R.A.M.C.
Capt. F. Harris, R.A.M.C.
Capt. A. C. Armstrong, Canadian A.M.C.
Capt. J. L. Stewart, M.C., R.A.M.C., attd. Gordon Highlanders.
Lieut. L. G. Fernie, R.A.M.C.
Capt. J. M. MacDonald, R.A.M.C.
Capt. T. C. Clarke, R.A.M.C.
Major J. W. Leitch, R.A.M.C.
Capt. J. M. Stalker, R.A.M.C., attached Royal Warw. Regt.
Capt. H. S. Sugars, R.A.M.C., attached West Yorks Regt.
Capt. R. A. S. Sunderland, R.A.M.C.
Capt. J. G. Brown, R.A.M.C., attached Royal Irish Fusiliers.
Capt. A. O. P. Reynolds, M.C., R.A.M.C., attached Devon R.
Capt. J. H. Brown, Australian A.M.C.

Missing.

Surgeon A. M. Russell, R.N.

Erratum.—Capt. J. Ewing, R.A.M.C., of Leeds, now temporarily stationed at Norwich, writes to say that he is not the same Capt. J. Ewing as was reported "Died of wounds" in THE LANCET of May 19th, 1917, p. 776. He reports that he is "as fit as the proverbial fiddle"—a condition upon which we congratulate the gallant member of our profession.

DEATHS AMONG THE SONS OF MEDICAL MEN.

The following sons of medical men must be added to our lists of those who have fallen during the war:—

Capt. C. A. R. Gatley, R.A.M.C., attached the Buffs, son of Dr. H. R. Gatley, temporarily Assistant Medical Officer at Maidstone Asylum.
Capt. V. O. Todd, Royal Lancaster Regiment, second son of Col. O. Todd, A.M.S.
Capt. B. R. Poole, Canadian Army Veterinary Corps, youngest son of Surg.-Major G. K. Poole, of Upper Norwood.
Second Lieut. H. E. K. Eccles, Royal Flying Corps, eldest son of Dr. E. T. Eccles, of Hove, Sussex.
Lieut. P. H. G. Pye-Smith, Liverpool Regiment, only child of the late Dr. P. H. Pye-Smith, F.R.S.
Capt. A. H. Ardagh, Canadian Infantry, only son of Dr. A. P. Ardagh of Orillia, Ontario, Canada.
Second Lieut. M. W. A. Sandoe, Devonshire Regiment, eldest son of Dr. J. W. Sandoe of Broadclyst, Devon.

FOREIGN DECORATIONS.

Russian.

Order of St. George (4th Class).—Capt. J. A. Sinton, V.C., I.M.S.
Order of St. Anne (2nd Class, with Swords).—Lt.-Col. and Brev.-Col. J. M. Sloan, D.S.O., R.A.M.C.
Order of St. Stanislas (2nd Class, with Swords).—Lt.-Col. and Brev.-Col. M. H. G. Fell, R.A.M.C.

French.

Légion d'Honneur.—Croix de Chevalier: Maj. W. H. Tucker, I.M.S. *Croix de Guerre:* Capt. J. Angus, R.A.M.C., Lowland Field Amb.; Capt. O. Teichmann, R.A.M.C., attd. Worc. Yeo.; Maj. M. F. White, I.M.S.

THE UNITED STATES AND MEDICAL ORGANISATION FOR THE WAR.

Arrival in England of American Medical Contingents.—A contingent of medical men and nurses, ranking as a regular unit of the American Army has arrived in England on its way to France. The surgeons and nurses were received by the King last Wednesday, who welcomed them in the following speech :—

It is with the utmost pleasure and satisfaction that the Queen and I welcome you here to-day. We greet you as the first detachment of the American Army which has landed on our shores since your great Republic resolved to join in the world struggle for the ideals of civilisation. We deeply appreciate this prompt and generous response to our needs. It is characteristic of the humanity and chivalry which have ever been evinced by the American nation that the first assistance rendered to the Allies is in connexion with the profession of healing and the work of mercy.

The unit, which has a personnel of between two and three hundred, has been organised by, and is under the direction of, Professor G. W. Crile, the leader being Major Harry L. Gilchrist. In addition to the professional staff of 20 doctors and surgeons there are 65 nurses and three companies of orderlies. Harvard University has supplied 90 per cent. of the personnel, the remainder having been recruited from a number of other universities.

A second American medical contingent has now arrived in this country. It consists of 26 doctors, 60 nurses, and 250 orderlies.

Recent numbers of the *Journal of the American Medical Association* give an illuminating account of the administration of the Medical Department of the United States Army. The department is divided into the Medical Corps, Medical Reserve Corps, Nurse Corps, Dental Corps, Veterinary Corps, and the enlisted men of the Hospital Corps. After June 1st there will be in addition a Medical Officers Reserve Corps. The Medical Corps, which consists of commissioned officers, numbered 443 in June last, 150 additional officers having been placed on the roll since. The Defence Act of 1916 made provision for an additional 1000. In round numbers, each division of 20,000 men requires 100 medical officers for service with the division, in addition to those attached to hospitals in the rear. The Medical Reserve Corps is designed to furnish temporary medical officers for service with the Army in time of war, the numbers in June last being 1767 on the inactive list and 146 on the active list—i.e., men making good the shortage of officers in the regular corps, including those who took part in the recent concentration on the Mexican border. Previous to the formation of a reserve corps, contract surgeons were employed; but this plan was discarded as unsatisfactory to the Government as well as to the officers themselves. The Dental Corps, organised in 1911, consisted in June last of 40 regular dental surgeons and 35 acting dental surgeons. In the Spanish-American war a large number of volunteer nurses were employed; but the experience was not wholly satisfactory, and a Nurse Corps was organised in 1901, consisting of a superintendent, chief nurses, nurses, and reserve nurses and numbering at present 150 on the active list. The enrolled nurses of the American National Red Cross Nursing Service constitute the reserve of the Army Nurses' Corps. What are called the Sanitary Troops are employed for the care of the wounded and their transport to dressing stations, field and other hospitals. Between 5000 and 6000 men belong to the corps.

The Duties of Military Medical Officers.—The medical officers of the Army have duties similar to those of civilian life, opportunity being allowed for development in special branches of medicine or surgery. As a sanitary officer the medical man acts in an advisory capacity, reporting to his commanding officer, who has himself been instructed in sanitary matters and is in a position to appreciate the value of recommendations made to him. Examination of recruits is also part of the duties of the medical department, it being recognised that "it is of much more importance to obtain a small number of men physically effective than a large number of men liable to spend time in hospital and receive a pension on their discharge from the service." The medical officers deliver lectures to commissioned officers on personal and camp hygiene, while the men are instructed in personal hygiene and on the moral and physical aspects of venereal disease. Medical officers of the rank of major receive instruction in sanitary tactics. In time of war each divisional commander of 20,000 men has on his staff a medical officer of the rank of lieutenant-colonel, who is divisional surgeon with complete control of the medical department, and a sanitary inspector of corresponding rank under him. A new departure is the appointment of a divisional sanitary inspector who may be authorised by the divisional commander to remedy sanitary defects without reference to higher authority and without the delay "incident to the so-called 'red-tape' of the service."

OBITUARY OF THE WAR.

TOM WELSH, M.B., CH.B. EDIN.,

MILITARY CROSS;
CAPTAIN, SOUTH AFRICAN MEDICAL CORPS.

Captain T. Welsh, who was killed in action on April 13th, was younger son of the late James Welsh, of Edinburgh, and was educated at Merchiston School and Edinburgh University. Graduating in 1910, he filled resident medical and surgical posts at the Royal Infirmary, Edinburgh, and the Ramsgate General Hospital, afterwards going to South Africa as assistant medical officer to the Knight Central Mines at Johannesburg. He volunteered for service in the campaign against German South-West Africa, and in November, 1914, he accepted a commission as captain in the 1st South African Field Ambulance, being sent to Egypt for four months. Returning to France in April, 1916, he was mentioned in despatches after the fight at Delville Wood, and was awarded the Military Cross for conspicuous bravery at the Somme. "He displayed great courage and determination in organising and leading stretcher-parties under very heavy fire."

A medical friend writes of Captain Welsh: "Self-sacrifice and duty were the watchwords of his life, and in all he thought and did he was unselfish; he was always a joyous happy boy, simply because his honest and upright mind was far removed from evil. His life was sacrificed in an attempt to succour wounded men from a village which was being systematically shelled to the ground by the enemy. Tom Welsh leaves behind him keen regrets in the hearts of his friends."

JAMES RAE, M.A., M.D. ABERD.,

LIEUTENANT, ROYAL ARMY MEDICAL CORPS.

Lieutenant Rae, who was reported missing, believed drowned, on April 15th, on his way to Egypt on the troopship *Arcadian*, was second son of William Rae, advocate, of Aberdeen. He was educated at Aberdeen University and University College, London, taking his M.A. Aberd. in 1904 and qualifying in medicine in 1909. Two years later he took his doctorate with commendation, presenting a thesis on the Deaths of the Kings of England which afterwards appeared in book form, affording entertaining reading and containing an excellent bibliography. After holding resident appointments at the Children's Park Hospital, Hither Green, and the Selly Oak Infirmary, Birmingham, he joined the Royal Army Medical Corps and was appointed registrar to the Connaught Hospital, Aldershot. Whilst there he contributed to our columns an analysis of the Duration of Treatment in 1500 Cases, showing that return to duty occurred after an average of 28 days' treatment and at an average cost of £4 per man. Before sailing for Egypt he had been for a year resident surgeon at the 1st Birmingham War Hospital. Lieutenant Rae married in 1915 Alison B. Wells, youngest daughter of Thomas Wells, late of Edgbaston, Birmingham.

JOHN HENRY EDWARD AUSTIN, L.R.C.P. EDIN.,

COLONEL, ARMY MEDICAL SERVICE.

Colonel J. H. E. Austin, whose death took place in a military hospital in London on April 26th, was son of the late Rev. Edward Austin, of Rendlesham, Suffolk. He received his medical education at St. George's Hospital, London, qualifying in 1887, and joining the Royal Army Medical Corps four years later. He was specially promoted major for active service in the field in 1900, becoming lieutenant-colonel in 1912, and finally, in 1915, Colonel in the Army Medical Service.

In his earlier years he was stationed at Woolwich and was from 1893–96 in India, where he served at Belgaum, and afterwards at Mandalay and other places in Burma. In July, 1898, he was in Egypt with the Nile Expedition, receiving the British and Egyptian medals. He accompanied the 2nd Grenadier Guards to South Africa in 1900, serving with them during the greater part of the South African War, and was mentioned in despatches, receiving the Queen's medal with three clasps and the King's medal with two clasps. From 1902–6 he was at Singapore. In 1910 he was posted to the London District for recruiting duties, a subject in which he took considerable interest, shown by his contributions to the *Royal Army Medical Corps Journal* on the subject. He held the appointment of Medical Inspector of Recruits in Scotland until he proceeded to France with the Expeditionary Force in August, 1914. He subsequently went to Egypt in charge of a general hospital, and was invalided home from that country in September, 1915, his death occurring after an illness of several months' duration. Colonel Austin's death will be deeply regretted by a large circle of brother officers and friends.

JAMES ALFRED GREGORY, M.R.C.S. ENG.,

LIEUTENANT, ROYAL ARMY MEDICAL CORPS.

Lieutenant J. A. Gregory, who died of wounds received in France on April 13th, at the age of 26, was only son of Mr. R. Gregory, of Standish, Lancs. He was educated at the Manchester Grammar School, and studied medicine at Manchester University, qualifying in 1914, when he became house surgeon to the Evelina Hospital for Children. In June, 1916, he obtained a commission in the R.A.M.C., going out to France in the following November. He was wounded by a shell as he was taking part in an advance with the regiment to which he was attached, only surviving his injuries for a few hours. His reputation with his superior officers was that of a man always cheery and thorough in his work, even under the most trying conditions. Lieutenant Gregory was recently married to Mollie Waddington, formerly of Wigan, Lancs.

Correspondence.

"Audi alteram partem."

THE LUMLEIAN LECTURES AND MEDICAL RESEARCH.

To the Editor of THE LANCET.

SIR,—The articles and correspondence dealing with the Lumleian Lectures and Soldier's Heart that have recently appeared in THE LANCET have interested me, not only on account of the subjects themselves but because they throw a light upon a much wider aspect of medical science. True science is always progressive, and medical science fortunately can show progress, though at times it may be timorous and halting. At uncertain periods new ideas arise, or perhaps it would be better to say modifications of old ideas, for it is often difficult to trace the origin of any new idea. One man may get an idea from another and apply it in a different manner, and it may have a more fruitful result in its newer application. So when I speak of newer conceptions I mean it with this limitation.

I wish to show how the newer conception of investigation in clinical medicine differs from the conception of the past. The two different conceptions are excellently illustrated by the recent contributions to THE LANCET. We have, on the one hand, the results of the newer methods given in some detail, and we have representatives of the older school criticising them. We see in this little arena the characteristics of the warfare between progress and reaction carried on as it is in all the ages and in every sphere of human thought. The reactionary calling attention to the wisdom of the past, angry and indignant, but unable to comprehend the significance of the change that has come over the scene. The time will come when what I refer to now as the new conception will in its turn be replaced by other views.

Though the two opposing views have a bearing on the whole field of clinical medicine, the particular field of cardiology serves to illustrate the differences in a manner easily demonstrated. Clinical medicine up till now has dealt mainly with the later stages of disease, seeking for physical signs of disease, and the changes in the tissues after the disease has damaged the organism. This, of course, was a necessary stage in the advance in medicine, and it has given us facts sound and solid which we can use as steps to further knowledge. But having gone so far there has come a period when the field is nearly exhausted, and the necessity arises for a new conception if progress is to continue. At this stage some wish to progress one way and some another, and a good deal of confusion arises. Many eminent clinicians have looked around and have stated that no progress can be made until new instrumental methods are discovered and they look to the laboratory workers for assistance. If we look at recent books on diagnosis we shall find practically no advance in the last 30 or 40 years save for some new laboratory methods.

There has, however, gradually taken shape a conception of research in clinical medicine which can show a distinct advance, and though aided by instrumental methods, yet the more important observations have been discovered without accessory aids. This advance has been due to a fuller appreciation of the importance of symptoms and has necessitated the more accurate investigation into the sensations of the patient, and into the mechanism by which sensations and objective signs are produced, and the effect the cause of the symptoms has upon the health of the patient. This has required the patient observation of individual cases for long periods in order to note the progress of the disease and the careful recognition of all associated signs and symptoms.

Many people reading of the results of these methods will scoff and say that there is nothing new in them, that they had been pursued for years. If, however, we appreciate the mental attitude of your correspondents towards the recent researches in cardiology, the difference in the points of view will be realised.

We have Dr. F. J. Smith criticising—*more suo*—the Lumleian lecturer, as he criticised me some years ago on the supposition that I did not know that Sir A. Clark had taught that murmurs may have no significance. I was perfectly aware of Clark's views. I remember reading his address at the Brighton meeting of the British Medical Association in 1886 when he set them forth. They were to this effect: A great many people's hearts showed murmurs in whom heart failure, as he conceived it, did not arise. Now the fact that murmurs may be of little or no significance has long been recognised, but what Sir A. Clark failed to do, and what most other writers failed to do, was *how to assess the value of a murmur and to differentiate the murmurs that are of significance from murmurs that are of no significance.* There is a belief held by many that this differentiation has been achieved. Thus in his letter to THE LANCET Dr. A. Morison states that negligible cardiac bruits are usually easily diagnosed and have frequently been fully appreciated. Would he tell us where? He is a voluminous writer on cardiac matters. Will he point out a single instance where he has given with clearness and precision a description of how murmurs can be differentiated to show those that are innocent and negligible from those that imply danger? Would he also tell us where in his own writings, or in the writings of others, the principles for assessing the value of murmurs are indicated? His remarks, so far as I have read them, are of that oracular type from which any conclusion can be drawn, and full of that vague warning that danger may lurk, but where it lurks he never tells. If he would favour us with the information so that a reader of average intelligence could understand he would confer a benefit on mankind.

The assumption of a knowledge where there is no real knowledge is also evident in connexion with irregular heart action. Dr. Smith seriously tells us: "of irregularity and its effect or lack of effects, clinically, Clark and Sutton knew as much as we do now." If Dr. Smith means himself and men of his way of thinking he is probably right. This unjustifiable assumption of knowledge is typical of the older school. I remember about 20 years ago, when I was studying heart irregularities and had got a basis for differentiating some of them on physiological lines, I was engaged in working out their clinical significance. At that time there was advertised the forthcoming publication of a cyclopædia of medicine to which the leading English physicians were to contribute. I looked eagerly for the publication of the heart volume, for at that time I had no doubt that the great London physicians would be able to remove my keenly felt ignorance. Judge of my surprise when I got the volume to find that save for some incidental references the matter of heart irregularity was ignored. Considering the extraordinary frequency of irregular hearts among my patients, its association with health and varying degrees of ill-health, I was astonished, and so had the temerity to write a letter to the very distinguished physician who edited the cyclopædia, and who had himself contributed some of the heart articles, calling attention to the omission. Seeing what we now know of the great importance of a knowledge of irregular heart action, I always smile when I remember his reply, which was to this effect: "The significance of irregular heart action is a matter of common knowledge, and being so well known it was not considered necessary to deal with it in the cyclopædia." Is not this a delightful illustration of the academic mind, "What I don't know is not knowledge"!

It cannot be too strongly emphasised that our knowledge of the significance of murmurs is still wofully deficient. I have tried, indeed, to solve the problem, as others have done before me, but our united efforts still leave a great deal to be done. The lack of success has been in a great measure due to the fact that we do not possess the knowledge to enable us to interpret the significance of the signs. To ascertain the significance of murmurs actually caused by a valve defect we must know the life-history of the individual. Thus we must watch individual cases during the illness which caused the damage, we must watch him for the remainder of his life and note the gradual changes that ensue if the damaged valve leads to heart failure. We must realise wherein the danger lies—as, for instance, that the danger is really caused not by the damaged valve but by the heart muscle not being able to overcome successfully the embarrassment to its work caused by the damaged valve. This, then, calls for the recognition of the signs and symptoms evoked by the embarrassed muscle. These are extremely elusive and varied, as they include alterations in

the size and shape of the organ, variations in the rhythm and rate of the heart; while the impairment of the efficiency of the organ may be manifested in the altered function of other organs. Many of these phenomena have not yet been accurately recognised, and it is towards their elucidation that the more recent investigations are directed.

To illustrate the necessity for this line of research one has but to point out how limited is our knowledge of such well-marked murmurs as the presystolic mitral murmur and the aortic diastolic murmur. I have followed the above line of investigation in regard to the former and have dimly perceived the factors that enable me to assess the value of this murmur, but I am far from asserting that I have succeeded in completely solving the problem. I have attempted the solution of aortic regurgitation, but must confess myself baffled in accounting for the heart failure in many of these cases. I have seen the heart failure fatally precipitated by the onset of an abnormal rhythm as auricular fibrillation or auricular flutter, but there are many cases where heart failure sets suddenly in, without the occurrence of an abnormal rhythm, in a manner characteristic of no other condition. I am distinctly of opinion that in aortic regurgitation there occurs something in the heart peculiar to this condition which I cannot link up with the heart failure arising in other conditions. It will thus be seen that though we have made a little advance in our attempts to assess the value of murmurs much has yet to be done, and that those who fancy they know all about the matter imagine a vain thing.

Another great field of research that lies practically unexplored is the action of remedies. It is a curious fact that there is not a single drug employed by the profession whose action in the human body has been accurately observed. I know this statement will be strongly disputed, but I have only to point out how lamentably ignorant we are of the action of cardiac remedies to show the truth of the statement. I suppose there is no drug during the past 150 years that has been the subject of so much discussion as digitalis. Thousands of physicians have lectured upon its effects and numerous physiologists and pharmacologists have experimented with it, yet they have missed the fundamental principles governing its action. Some years ago I collected the records of all the cases to whom I had given digitalis for 10 years. When I analysed the results I was struck by the varied reaction to the drug. Many of these reactions were a puzzle to me, but continuing the investigation the matter gradually became clearer, and I found that the reaction in a great many cases varied with the nature of the disease present in the heart. Thus in one case heart-block would be produced, in another extra-systoles, in another auricular fibrillation, while in a great many the digitalis, though pushed to the furthest limits, seemed to have no effect upon the heart. Moreover, hearts affected by an abnormal rhythm responded differently; thus cases, with what now we know as auricular fibrillation, responded in one way, while others with auricular flutter reacted in another way.

To help to solve these peculiarities I searched diligently the literature, beginning with the original articles of Withering published in 1785. I searched the literature in the English, French, and German languages, and in the whole of this literature there was not recorded a single case where the condition of the heart was clearly detailed, and the reaction intelligently described. I mention this not to reflect upon the intelligence of the physicians of the past, but to show the necessity for a new conception in clinical investigation. This will be appreciated if I state briefly two main reasons for the failure of the past observers to find out the action of digitalis on the human heart. First, physicians were unable to recognise its effect because medical science had not advanced so far as to enable them to diagnose the heart condition, nor the abnormal rhythms which modified the action of digitalis. Second, experimentalists failed because they did not know that digitalis reacted according to the nature of the lesion with which the heart was affected, but assumed that the reaction they got in the healthy hearts of animals would be the same in the diseased human heart.

The true conception of clinical investigation should be to make the recognition of a new fact a step to further knowledge. This is, of course, recognised in theory, but it is not always put in practice. We have seen this in regard to Sir A. Clark's attitude to murmurs, and we see it in your correspondent, Dr. Poynton's, attitude to the discovery of the rheumatic microbe. It is now many years since he announced his discovery, and so far as I know he has done nothing with the discovery but to repeat the announcement. When I was a student, nearly 40 years ago, people were describing the discovery of the rheumatic microbe, and others have done the same thing since; but from that day to this no sufferers from rheumatic fever have derived the slightest benefit from the discovery, nor has the discovery added anything to our clinical knowledge. In place of being content with the announcement of the discovery, investigators should carry the matter further by studying out the life-history of the microbe—how it gets entry into the body, the signs of its earliest invasion, and how these signs differ from the effects of other morbific agents, its susceptibility to remedies, &c. Such are some of the lines that Dr. Poynton might have pursued. This instance illustrates the attitude of much bacteriological discovery; as many people, having recognised a microbe, do not know what to do with their discovery.

If I have succeeded in making my point clear, the need for a new conception in the investigation of disease will be realised. The conception I am advocating is not limited to the investigations of the circulatory system, but the principle must be applied to the symptoms produced by every organ in the body. This principle involves the careful perception of every symptom, subjective as well as objective, an investigation to find out the mechanism of its production, and the bearing that the cause of the symptom has on the individual's life-history. We have greatly benefited by the laborious and careful histological examination of the tissues in health and disease, we must now turn our attention to an equally careful investigation of the symptoms of disease. The methods employed differ widely, and as no trouble is spared to make a competent microscopist, no trouble should be spared to make a competent clinical observer.

In thus insisting upon new methods for clinical investigation it is not necessary to reflect in any way upon the older physicians. They did their work according to their lights, and we do ours according to our lights. The time will come when other ideas will supersede ours, and we must rejoice thereat, as it will be for the advance of knowledge. Nor must we neglect the investigators of the past, for the work they have done is invaluable, and if to-day we can make some progress it is because they have prepared the way. I am conscious of a great debt of gratitude which I owe to the great physicians of the past. I have been an earnest student of the writers of the past, Morgagni, John Hunter, Wilkinson King, Stokes, and the more recent writers, as Gairdner, Sutton, Broadbent, Balfour. I have a fairly comprehensive knowledge of the literature dealing with the circulatory system, and I am convinced that in no other language are the writers superior to those of these islands for breadth of outlook, philosophic thought, and sanity of judgment. It is ever a pleasure and an instruction to turn to the writings of the world's greatest clinical investigator, John Hunter. If anyone wishes to understand what clinical investigation is let him study the writings of this remarkable man, and then let him visit the College of Surgeons Museum, and if good fortune attends him get a chat with Arthur Keith.

I am, Sir, yours faithfully,

May 15th, 1917. J. MACKENZIE.

A RAPID METHOD OF OBTAINING ANAEROBIC SPORE-BEARERS IN PURE CULTURE.

To the Editor of THE LANCET.

SIR,—In your issue of May 12th Captain W. J. Wilson describes an easy method of obtaining plate cultures of anaerobes. As Miss Muriel Robertson suggests, however, in the *Journal of Pathology and Bacteriology*, and again in her letter to THE LANCET of May 19th, this is only the beginning of difficulties. Before proceeding to investigate a particular variety of spore-bearer isolated by the plate method it is of the utmost importance to determine its purity. That laboratory strains of *B. tetani*, hitherto regarded as pure, should, as Miss Robertson indicates, turn out to be a symbiotic mixture is further evidence of the need for the most careful verification of the purity of the organism as a preliminary to further work.

It is obvious that the usual laboratory method of repeated plating is not reliable. The ideal method would, of course,

be to raise a culture from a single cell. Such a method was introduced by Burri in which Indian ink is used as a dark ground for the bacteria. This particular method, however, is open to certain objections, one of which is the risk of contamination owing to the necessary exposure of the glass slips. Moreover, such a method demands considerable time and skill, the latter of which is not acquired in a day. Where time is a matter of some moment I would suggest the following alternative:—

An isolated colony or part of such a colony is picked off from the solid medium with a platinum needle, and a suspension of this material is made in one or two c.c. of sterile saline. An old colony is perhaps preferable where there is practically nothing left but spores. After vigorous shaking a sample of this suspension is transferred to a hæmocytometer stage, or preferably to a counting chamber such as has been devised by Professor Ernest Glynn for the numerical estimation of bacteria in vaccines. Having ascertained the number of spores or bacilli per c.c. in the suspension, it is an easy matter to make from this a dilution which will contain approximately one spore or one bacillus per unit of saline. When the desired dilution has been obtained, it is an easy matter to sow a series of meat or Hirnbrei tubes each with the unit volume of saline containing a single organism or spore. These are then incubated anaerobically, and thereafter examined as to their purity. If a sufficiently high dilution has been made there is every probability that a pure strain or strains will be secured.

The method is simple, does not take up much time, reduces the possibility of extraneous contamination to a minimum, and, short of raising a culture from a guaranteed single bacillus, as the ideal method would be, offers a very reasonable prospect of success.

I am, Sir, yours faithfully,

ROBERT DONALDSON,
Pathologist, Royal Berks Hospital.

Reading, May 20th, 1917.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

To the Editor of THE LANCET.

SIR,—In spite of the fact that a circular has been issued stating that the "National Committee for Relief in Belgium" is ceasing to take part in the relief of the suffering in Belgium, this Committee (The Belgian Doctors' and Pharmacists' Relief Fund), as the result of a letter received from "The Commission for Relief in Belgium," has decided to continue to send £800 a month to the Committee in Brussels. The letter contained the following words:—

"Every arrangement has been made to assure that the relief shall go on without interruption. Spanish and Dutch representatives will take the place of the Americans, and the actual handling of the relief cargoes, the distribution of money, &c., will be supervised by Belgian representatives of the Commission in a way which we feel confident will ensure the food and funds arriving at their proper destination. ..... I therefore hope that you will be able to continue the ..... contributions from your society as in the past. They have afforded great relief."

I am, Sir, yours faithfully,

H. A. DES VŒUX,
Honorary Treasurer.

14, Buckingham-gate, London, S.W. 1, May 23rd, 1917.

THE EXAMINATION OF THE BLOOD OF TYPHUS FEVER CASES BY DARK-GROUND ILLUMINATION.

To the Editor of THE LANCET.

SIR,—A few days after the publication of the letter sent to you by Dr. Georgina Darling and myself,[1] the examination of a large number of "controls" demonstrated that the spirochæte-like bodies found in the blood of typhus fever cases were also present in the blood of other patients, and even in that of healthy subjects. I am therefore in entire agreement with the remarks of Lieutenant-Colonel L. W. Harrison, R.A.M.C., in his letter of April 29th. I think Colonel Harrison has done good service in describing these "streamers," and in this way preventing others being deceived by them. I would have written earlier, but my sudden departure overseas prevented me.

I am, Sir, yours faithfully,

W. JAMES WILSON,
Captain, R.A.M.C. (T.F.).

B.E.F., May 20th, 1917.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Appeal Pensions Tribunal.

THE two medical representatives on the tribunal which is to hear appeals from decisions awarding gratuities to sailors and soldiers discharged as medically unfit are Mr. BILTON POLLARD, of the Royal College of Surgeons, and Dr. NORMAN MOORE, of the Royal College of Physicians.

HOUSE OF COMMONS.

WEDNESDAY, MAY 16TH.

Medical Re-examinations.

Answering Mr. NEEDHAM, Mr. MACPHERSON (Under Secretary for War) said: Owing to the very great pressure on the medical boards it is impossible to set up at present a system of anticipatory medical examinations in connexion with the Military Service (Review of Exceptions) Act. It is hoped, however, as soon as may be, to afford facilities for men who desire to be medically examined in advance of the date on which, under the Act, they would be liable to be called up for re-examination, and where under such authorised anticipatory medical examination a man is found to be permanently and totally disabled for military service he will receive a final discharge in accordance with the provisions of the Act.

In reply to Mr. PENNEFATHER, Mr. MACPHERSON said: The Military Service (Review of Exceptions) Act, 1917, expressly defines the limits within which notices requiring re-examination are sent to discharged sailors and soldiers. In order to avoid error, the form of notice bears on the face of it a statement that it does not apply to any officer or man who has left or been discharged from the naval or military service of the Crown in consequence of disablement, if the disablement has been certified under the authority of the Admiralty or of the Army Council to be the result of wounds, including injury from poisonous gas, received in battle or in any engagement with the enemy or otherwise from the enemy, or in consequence of neurasthenia or any allied functional nerve disease, if so certified by a special medical board to be the result of naval or military service in the present war. For a man who considers that he falls within this exclusion a form of claim is printed on the back of the notice, which is to be returned to the recruiting officer in order that inquiries may be made.

THURSDAY, MAY 17TH.

Medical Examination of Female Prisoners.

Commander WEDGWOOD asked the Home Secretary what further steps had been taken in investigation of the Brentford case; and whether the magistrate who ordered the medical examination of two innocent women was still administering justice in the Brentford district.—Sir GEORGE CAVE replied: I have made inquiries into this case, and am informed that the magistrates did not order an examination of the two women referred to. The women were charged with disorderly behaviour, and the magistrates, after hearing part of the evidence, remanded them for inquiries, and endorsed upon the committal order a statement that the justices would be obliged by the opinion of the medical officer as to whether the women were suffering from disease. I have informed the magistrates that in my opinion this request should not have been made. In consequence of the magistrates' request the two women were medically examined at Holloway Prison, with the result that they were reported by the deputy medical officer to be free from disease. The prison medical officers have definite instructions that no woman is to be examined without her consent, and I am assured that in this case the necessary consents were obtained. On the hearing of the case being resumed, the magistrates dismissed the charge. It appears from the information given to me that no illegality was committed, but I desire to repeat that in my opinion there was no reason whatever why the magistrates should have asked for any opinion from the medical officer and I regret that the request was made.

Mr. LEIF JONES: Are prisoners made aware that they may refuse their consent to such examination?—Sir GEORGE CAVE: I understand that they are always told they may refuse.

Prisoners and Venereal Disease.

Answering Commander WEDGWOOD, who asked whether in a certain prison girls due for discharge were obliged to submit to a medical examination, and if found suffering from venereal disease were detained beyond their sentence, Sir GEORGE CAVE said: Under Statutory Rule 11 all prisoners must be examined before discharge. No prisoner is locally examined for venereal disease without consent. No prisoner

can legally be detained beyond the expiration of sentence and no prisoners are or have been so detained.

MONDAY, MAY 21ST.

Committee of Reference under Military Service Act.

Sir WILLIAM COLLINS asked the Under Secretary for War who were the members of the Committee of Reference of the Royal College of Physicians of London and the Royal College of Surgeons of England; whether it was appointed under Section 7 of the Military Service Act, 1916 (Session 2); by whom its members were selected; and with what powers and duties it had been entrusted.—Mr. MACPHERSON wrote in reply: The Committee of Reference is composed of the following: the chairman is the President of the Royal College of Physicians, and the members are four Fellows of the Royal College of Physicians, with the President and four Fellows of the Royal College of Surgeons. This committee was appointed under Section 7 of the Military Service Act, 1916 (Session 2), and the Military Service (Professional Committees Regulation) Order, 1916, as the Committee of Reference for Section 5 of these Regulations. The members were appointed by the Royal Colleges of Physicians and Surgeons and approved by the Army Council. Their powers and duties are contained in the Regulations mentioned.

Medical Students.

Mr. T. E. HARVEY asked the Under Secretary for War whether any further steps were to be taken to recall from the ranks medical students now serving in the Army with a view to their employment in medical and surgical work; and whether, in view of the need for additional doctors and surgeons, arrangements could be made for the employment of advanced medical students in responsible work in the Royal Army Medical Corps and military hospitals similar to that of surgeon probationers in the Navy.—Mr. MACPHERSON answered: Fourth and fifth years' students can be released, if serving, to continue their studies. Their employment with the Army is not considered desirable, as it is thought better to wait until they can be commissioned as medical officers.

Military Hospital Huts at Cromarty.

Mr. MORTON asked the Under Secretary for War whether any of the military hospital huts at Cromarty were to be used as a hospital for the treatment of venereal disease; and, if so, would he have the matter fully inquired into and further considered before anything of the sort was allowed.—Mr. MACPHERSON replied: This matter is now being considered.

Voluntary Aid Hospitals.

Sir WILLIAM COLLINS asked the Financial Secretary to the War Office whether any, and if any what, grants were made to voluntary aid hospitals in respect of medical services rendered by civilian medical men, and what were the conditions regulating any such grants.—Mr. FORSTER wrote in reply: Very large numbers of civilian medical men have rendered, and are rendering, such services gratuitously, and services so rendered the War Office gratefully receives. If a civilian doctor in the exercise of his own discretion sees fit to claim payment for his services, the General Officer Commanding has power under the War Office instructions to allow suitable remuneration, having in view the circumstances of each case, and in that case the grant to the hospital in question is increased by an equivalent amount.

WEDNESDAY, MAY 23RD.

Promotions in the R.A.M.C. (Territorial Force).

Mr. LYNCH asked the Under Secretary for War (1) whether, notwithstanding that a field ambulance of the Territorial Forces was a definite unit even in peace time and its establishment was laid down as consisting of a lieutenant-colonel, two majors, and others, promotions to these posts were being withheld for long periods although suitable men were recommended for them, and, if so, whether this state of affairs would be remedied; (2) whether vacancies on the medical staffs of field ambulances of the Territorial Forces were frequently filled by promoting officers of the Royal Army Medical Corps (Regular Forces), to the exclusion of Territorial officers of longer service, notwithstanding that such officers had been recommended for promotion by their commanding officers; and whether, in fairness to medical men who gave their services to the Territorial Force before the war, promotions would be regulated by considerations of merit and of work performed; and (3) whether all applications for promotion made on behalf of medical officers of the Territorial Forces who joined prior to the outbreak of war were now refused on the plea that promotions in the Royal Army Medical Corps were in abeyance; and whether steps would be taken to facilitate promotions which had been earned by long and faithful service.—Mr. MACPHERSON replied: It is not the fact that all promotions in the Royal Army Medical Corps (Territorial Force) are refused on the grounds stated. When suitable officers with the requisite qualifications, service, and experience are available, promotions are made. Only when such officers are not available for command are regular or temporary officers of the Royal Army Medical Corps brought in. Promotion in the Royal Army Medical Corps (Territorial Force) is now under consideration by the committee of which the Member for Dundee (Mr. Churchill) is chairman.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

BRADBURNE, A. A., F.R.C.S. Eng., has been appointed Honorary Ophthalmic Surgeon to the Victoria Memorial Hospital, Manchester.

LLOYD, E. LEWYS, County Medical Officer of Health and School Medical Officer for Merioneth.

MCKINNEY, W. B., Medical Officer of Lisnaskea Dispensary District and Union Hospital *pro tem.*

NORMAN, HUBERT J., M.B., Ch.B. Edin., D.P.H., Lecturer on Mental Diseases at the Westminster Hospital.

To be Certifying Surgeons under the Factory and Workshop Acts: DYSON, P. A. S., L.R.C.P. Lond., M.R.C.S. (Grosmont District of the county of Yorks, North Riding); JAMES, S., L.R.C.P. Lond., M.R.C.S. (Brynamman District of the county of Carmarthen); JONES, R. F., L.R.C.P. Lond., M.R.C.S. (Tamworth District of the county of Stafford); O'CLERY, L., M.D., M.Ch. R.U.I. (Clonakilty District of the county of Cork).

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).
When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

ANGLO-RUSSIAN HOSPITALS.—Surgeons.

BETHNAL GREEN, METROPOLITAN BOROUGH OF.—Female Assistant Medical Officer of Health. Salary £350 per annum.

BIRMINGHAM CITY EDUCATION COMMITTEE.—Temporary Assistant School Medical Officer. Salary £300 per annum.

BRISTOL GENERAL HOSPITAL.—Casualty House Surgeon. Salary at rate of £175 per annum, with board, &c.

BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN.—Female House Physician. Salary £150 per annum, with board, &c.

BRISTOL ROYAL INFIRMARY.—House Physician and House Surgeon. Salary at rate of £120 per annum, with board, &c.

BURNLEY, VICTORIA HOSPITAL.—House Surgeon. Salary £160 per annum, with board, &c.

CAPE TOWN, SOUTH AFRICAN COLLEGE.—Professors of Pharmacology, Pathology, and Bacteriology. Salary at rate of £800 per annum, each.

CARDIFF, KING EDWARD VII.'S HOSPITAL.—House Surgeon for six months. Salary at rate of £175 per annum, with board, &c.

CHARING CROSS HOSPITAL, W.C.—Honorary Anæsthetist.

CHESTER ROYAL INFIRMARY.—Assistant House Surgeon. Salary £150 per annum, with board, &c.

DEVONPORT, ROYAL ALBERT HOSPITAL.—House Surgeon, unmarried. Salary £150 per annum, with board, &c.

EDINBURGH ROYAL ASYLUM, Morningside.—Temporary Assistant Physician. Salary £365 per annum, with board, &c.

EVELINA HOSPITAL FOR CHILDREN, Southwark, S.E.—House Physician for four months. Salary at rate of £160 per annum, with board, &c.

GRIMSBY AND DISTRICT HOSPITAL.—House Surgeon. Salary £5 5*s.* per week, with board, &c.

ITALIAN HOSPITAL, Queen-square, London, W.C.—House Surgeon for six months. Salary £80 per annum, with board, &c.

LABORATORIES OF PATHOLOGY AND PUBLIC HEALTH, 38, New Cavendish-street, W.—Bacteriologist.

LANCASTER COUNTY ASYLUM.—Temporary Assistant Medical Officer. Salary 7 guineas per week, with board, &c.

LEEDS PUBLIC DISPENSARY.—Resident Medical Officer. Salary £200 per annum, with board, &c.

LEICESTER EDUCATION COMMITTEE.—Two Assistant School Medical Officers (Temporary). Salary £300 per annum.

MANCHESTER, ANCOATS HOSPITAL.—House Physician. Salary £200 per annum, with board, &c.

MANCHESTER, BAGULEY SANATORIUM FOR TUBERCULOSIS.—First Assistant Medical Officer, unmarried. Salary £400 per annum, with board, &c.

NEWCASTLE-UPON-TYNE, ROYAL VICTORIA INFIRMARY.—Resident Medical Officer. Salary as arranged, with board, &c.,

NEW HOSPITAL FOR WOMEN, Euston-road, N.W.—Female Assistant Physician and Assistant Surgeon. Also House Physician, Obstetric Assistant. Two House Surgeons, salary £50 per annum, with board, &c. Also Resident Medical Officer at House of Recovery, New Barnet. Salary £60 per annum.

NOTTS EDUCATION COMMITTEE.—Assistant School Medical Officer. Salary £350 per annum.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—District Resident Medical Officer for four months. Salary at rate of £60 per annum, with board, &c. Also Pathologist and Registrar. Salary at rate of £80 per annum, with lunch.

QUEEN MARY'S HOSPITAL FOR THE EAST END, Stratford.—Casualty Officer.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—Temporary Assistant Physicians on Monday and Wednesday afternoons and Wednesday mornings for Out-patient Work. Salary £25 per annum, with lunch. Also House Physician, Casualty House Surgeon, and House Surgeon for six months. Salary £100 per annum, with board, &c.

ST. BARTHOLOMEW'S HOSPITAL, SPECIAL DEPARTMENT FOR THE DIAGNOSIS AND TREATMENT OF VENEREAL DISEASES.—Chief Assistant. Salary £500 per annum.

ST. HELENS COUNTY BOROUGH.—Temporary Assistant Medical Officer of Health. Salary £350 per annum.

SHEFFIELD, JESSOP HOSPITAL FOR WOMEN, GYNÆCOLOGICAL AND MATERNITY DEPARTMENTS.—Junior Female House Surgeon, unmarried. Salary £200 per annum, with board, &c.

SHEFFIELD ROYAL HOSPITAL.—Casualty Officer. Salary £130 per annum. Assistant House Surgeon. Salary £120 per annum, with board, &c.

SHEFFIELD ROYAL INFIRMARY.—House Physician. Salary £120 per annum, with board, &c.

SOUTH LONDON HOSPITAL FOR WOMEN, South Side, Clapham Common, S.W.—Female House Surgeon for six months. Salary at rate of £100 per annum, with board, &c.

STOCKPORT, COUNTY BOROUGH EDUCATION COMMITTEE.—School Medical Officer. Salary £300 per annum.

SWANSEA EDUCATION COMMITTEE.—Female Assistant School Medical Officer. Salary £300 per annum.

TAUNTON AND SOMERSET HOSPITAL.—Senior House Surgeon. Salary £250 per annum, with board, &c.

WORCESTER, KING EDWARD VII. MEMORIAL SANATORIUM, Knightwick, near Worcester.—Temporary Medical Superintendent and Tuberculosis Officer. Salary £450 per annum, with board, &c.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Cavan and at Totnes.

Births, Marriages, and Deaths.

BIRTHS.

ALTOUNYAN.—On May 16th, at High-street, Hampstead, the wife of Lieut. E. H. R. Altounyan, R.A.M.C.—a daughter.

BAILEY.—On May 21st, at Bracondale, Stockport, the wife of Lieutenant J. T. Bailey, R.A.M.C., of a daughter.

HAYDON.—At St. Denys, 52, Hermitage-lane, Platt's-lane, Hampstead, the wife of Arthur Haydon, M.D., F.R.G.S., of a son.

HOLROYDE.—On May 17th, at Barnsley, Yorks, the wife of Douglas Holroyde, M.A., M.B., B.C., of a son.

LANDMAN.—On May 15th, at The Towers, Roundhay, Leeds, the wife of Dr. Julian Landman, of a daughter.

MCKAY.—On the 9th instant, at Streatham, to Annie and Robert McKay—a son.

POWELL.—On May 12th, at a nursing home, Sheffield, the wife of Ievan Herbert Powell, M.B., Ch.B. Dub., of a son.

RIDDOCH.—On May 15th, at Devonshire-street, W., the wife of George Riddoch, M.D, R.A.M.C., of a son.

MARRIAGES.

FRASER—CHARD.—On May 15th, at Chichester, Major Alexander Edward Gordon Fraser, R.A.M.C., to Dorothy Louise Josephine, elder daughter of the late R. A. S. Chard, of Magnolia, West Tarring, Worthing.

JONES—FREEMAN.—On May 12th, at St. Peter's, Chertsey, Captain Arthur Beresford Jones, R.A.M.C., to Evelyn A., youngest daughter of Mr. and Mrs. Herbert L. Freeman, Burwood House, Chertsey.

NASMYTH—MAUDE.—On April 19th, at Salonica, Lieutenant Hugh Nasmyth, A.S.C., to Dorothea C. Maude, M.D.

SHAW—WILLANS.—On May 18th, at St. Mary's Church, Bedford, Captain Townsend Shaw (late I.M.S.), R.A.M.C., to Eva Jeune, daughter of the late Dr. W. B. Willans, Much Hadham, Herts, and of Mrs. Willans, Woburn-road, Bedford.

DEATHS.

BREW.—On May 16th, at his residence, Chew Magna, Bristol, Richard Hugh Brew, L.R.C.P. & S. Edin., aged 55.

BURTON.—On May 12th, of wounds received in action the same day, Percy Herbert Burton, M.R.C.S., L.R.C.P. (London Hospital), Captain, R.A.M.C., attached London Regiment, in his 50th year.

KIND.—On May 3rd, from gas poisoning in action, Robert Gordon Kind, R.A.M.C., aged 28.

LE PAGE.—On Sunday, May 13th, 1917, at Millmount, Guernsey, Dr. Wm. Le Page, L.R.C.P., L.F.P.S., L.S.A., aged 75 years.

PHILBRICK.—On May 14th, in India, John Harold Philbrick, M.B. Cantab., aged 42.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Professor W. J. R. Simpson, C.M.G., has been appointed Chief Medical Officer to the Serbian Relief Fund hospital unit.

CHILDREN'S HOSPITAL FOR HIP DISEASE, SEVENOAKS.—As a memorial to the late Miss Emily Jackson, who founded the Children's Hospital for Hip Disease, Sevenoaks, a fund has been started for the purpose of purchasing a piece of land adjacent to the hospital. Donations should be sent to the honorary treasurers.

Notes, Short Comments, and Answers to Correspondents.

MEDICAL MEN DURING BURNAND'S EARLIER PERIOD ON *PUNCH*.

STUDENTS of medical history are doubtless familiar with *Punch's* treatment of the theme of medical men. These from early days in all countries have been subjects of satire, but *Punch* was perhaps the first satirist to begin showing them a certain respect. Under the editorship of the late Sir Francis Burnand, which began in 1880 and covered most of the Keene and Du Maurier period, we get a change in *Punch's* treatment of what is popularly called "the doctor." In December, 1880, Du Maurier's drawing appeared of the senior surgeon being warned by the nurse, who, with uplifted forefinger, exclaims, "You cannot enter now, Sir George. We are just going to have evensong!" The picture of the eminent surgeon is admirable and complimentary, and our sympathies are with him in a difficulty which might occur to-day. Earlier in the same year, when Tom Taylor was perhaps still editor, the medical jokes are of the old type—not ill-natured, that is to say, but not exactly eulogistic of the profession. Even in the same number of *Punch* (Dec. 18th) there is an Irish medical referee, also drawn by Du Maurier, who talks with a broad brogue and humorously refuses to pass a candidate for a policy on the ground that he owns land in Ireland. In October of the same year two monthly nurses, drawn by Charles Keene, are discussing a baby. "'Well, Nuss,' sez he, 'igh and 'orty like, he sez, 'Wot do you think?' sez he. 'Doctor,' I sez, quite differential, I sez, 'I'm quite of your opinion,' I sez. 'And I'm of the same way of thinking, Nuss,' sez he. And so we settles it." And the Professional Friend, the other monthly nurse, asks with much interest, "Lor'! and wot was his opinion, now?" "Bless yer 'art, my dear Creetur, in course *he never hadn't given none!*" Another of Charles Keene's admirably drawn medical sketches depicts the doctor being told by an old lady, to whom he had spoken about the advisability of tapping, "Oh, Doctor, don't say that! Nothing was ever tapped in this house that lasted over a week!!" The doctor here is depicted as a rather stodgy old individual. In March Keene draws a genial absurd elderly gentleman, who is waving his hat to an equally absurd old lady of the period. "My dear Madam," says the medical gentleman, "always live on gravel." But the old lady is sure she could not digest it.

Going backwards a few years, we find a joke not quite creditable to the profession, although genial in the manner of the time. Charles Keene depicts Dr. Jolliboy, "who had been called away from a social meeting at his club," in the act of feeling an old gentleman's pulse. "Thirteen, fourteen, f'fteen-two, f'fteen-four, f'fteen-six—pair eight—nob'sh nine," says Dr. Jolliboy, and then "drops off," and Mr. Punch draws a veil, &c. This is in the *Punch's Almanack* for 1874. In November, 1875, a "Struggling Young Physician," well indicated by Du Maurier, tells the manservant to take Mr. Gladstone into the breakfast-room when he calls and to "ask him to be so kind as to wait a little while." Then turning to his lady patient the struggling medical man says: "Now, Madam!"

In 1863, when Burnand joined the staff of *Punch*, the medical jests—we speak always of illustrations only—depict astute formal old fellows, dressed for a part, as it were, with high Gladstone collars, stocks, coats representing a cross between evening dress and the frock coat, glossy top-hats, always carried into the sick-room, and double eye-glasses hung on a thick ribbon. "There is not much the matter with him," says a quaint "family doctor" in reference to a little boy, "but I am afraid we must cut off his animal aliment." And Tommy boo-boos and hopes that "it won't hurt." Here, of course, is the ancient tradition involved in the "we" and the grand unusual phrase.

THE ECONOMICAL USE OF COCAINE.

To the Editor of THE LANCET.

SIR,—In view of the present high price of cocaine, it is important to avoid waste in its use. As usually employed for local anæsthetic purposes, it is applied in solution on lint or cotton-wool, a considerable proportion remaining on the latter and being thereby wasted. Moreover, solutions of the drug, if they have been long made, are untrustworthy, and not infrequently have to be discarded. For some years I have used glycerine of starch as a vehicle for the local application of cocaine and with entire satisfaction, and can recommend it as the most economical. It has the following good points.

1. It keeps indefinitely. Does not evaporate, and consequently does not dry up. I have by me the remains of a supply made five years ago and it is as active as ever.
2. It can be applied to skin or mucous membrane without wool or lint. Simply spread it over the surface as thickly or thinly as desired.
3. It is very absorbable.
4. It can be prepared in any strength, cocaine being soluble in glycerine of starch in practically any proportion.
5. It is as convenient to handle as an ointment, but without the latter's greasiness.

By cocaine I mean, of course, the hydrochloride. The alkaloid itself is insoluble in glycerine preparations.

I am, Sir, yours faithfully,

Bournemouth, May 13th, 1917. J. T. HALL, L.D.S.

VITAL STATISTICS OF NYASALAND.

AN official report on Nyasaland for the year 1915–16 has just been presented to Parliament by the Colonial Office. From this it appears that the native population is estimated at 1,137,572, being approximately 505,121 males and 632,451 females. The number of European residents in the Protectorate, comprising officials and non-officials, during the year was 523 males and 262 females—total 785—and the Asiatic population amounted to 379. Amongst the Europeans 13 marriages were celebrated; the birth-rate was 26·75 and the death-rate 16·56 per mille.

The public health of the Protectorate was not altogether satisfactory during the year. An epidemic of small-pox broke out in the Lilongwe and Dowa districts, and out of 3535 cases there were 941 deaths. There were 29 cases of sleeping sickness recorded (principally in the proclaimed area of the Dowa district), as against 39 in 1914, 64 in 1913, 46 in 1912, and 38 in 1911. There were 621 cases of malaria, as compared with 729 in the previous year. As regards other mosquito or insect-borne diseases, there were 2 cases of blackwater fever and 29 of trypanosomiasis. In a special note on the European officials, it is stated that 10 were invalided, as against 7 in the previous year. There were 188 cases treated, with one death, as against 151 cases and no death in the previous year. Malaria accounted for 41 of the total admissions, or 22 per cent. Amongst the general European population there were 300 cases treated in 1915, as against 240 in 1914, the principal diseases in order of frequency being malaria, local injuries, and diarrhœa. These statistics do not include cases treated by Mission doctors.

STRETCHER-BEARING.

To the Editor of THE LANCET.

SIR,—As one deeply interested in the welfare of our wounded soldiers, I beg to call your attention to the dangerous practice of carrying seriously wounded men on stretchers *shoulder-high* prevailing at the front. In all cinema war-films the Hun prisoners engaged in carrying our poor wounded are shown doing so in this manner, which is decidedly wrong and very trying to the patient.

Is it not the case that General Stonewall Jackson, after being wounded, came to his death from a fall from a stretcher carried shoulder-high through one of his bearers being shot? The proper way to carry a patient on a stretcher is at full length of the arm.

I am, Sir, yours faithfully,

A. MACLURE,

West Hampstead, May 14th, 1917. Major, late London Scottish.

*** The carrying of the loaded stretcher shoulder-high can only be justified by exigencies of space. Strain on the bearers' arms should be avoided by shoulder-slings.—ED.L.

THE WOUNDED ALLIES RELIEF COMMITTEE.

THE Wounded Allies Relief Committee has removed from Grosvenor-gardens, and the headquarters of the organisation are now at Bank Chambers, 329, High Holborn, W.C. 1.

X.—Many kinds of depilatories have been used, generally containing a sulphide of an alkali or alkaline earth. Electrolysis affords good results in the hands of an expert. The necessity for depilation may be avoided by rendering the hairs less conspicuous by means of peroxide of hydrogen.

METEOROLOGICAL READINGS.

Other information which we have been accustomed to give in these "Readings" is withheld for the period of the war.

Medical Diary for the ensuing Week.

SOCIETIES.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital, Hammersmith-road, W.

FRIDAY.—8.30 P.M., Meeting.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—Hospital closed.
TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.
WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.
THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.
FRIDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.
SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patients (Mr. E. Gillespie). 2.30 P.M., Medical Out-patients (Dr. T. R. Whipham); Gynæcological Out-patients (Dr. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).
TUESDAY.—2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. Howell Evans); Nose, Throat, and Ear Out-patients (Mr. C. H. Hayton). Radiography (Dr. Metcalfe). 3.30 P.M., Medical In-patients (Dr. A. J. Whiting).
WEDNESDAY.—Clinics:—2.30 P.M., Throat Operations (Mr. C. H. Hayton). Children Out-patients (Dr. T. R. Whipham); Eye Out-patients (Mr. R. P. Brooks); Skin Out-patients (Dr. H. W. Barber). 5.30 P.M., Eye Operations (Mr. R. P. Brooks).
THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patients (Dr. A. J. Whiting); Surgical Out-patients (Mr. Carson); Radiography (Dr. Metcalfe). 3 P.M., Medical In-patients (Dr. R. M. Leslie).
FRIDAY.—2.30 P.M., Surgical Operations (Mr. Howell Evans). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. E. Gillespie); Eye Out-patients (Mr. R. P. Brooks).

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.
THURSDAY.—5.15 P.M., Clinical Lecture.

ROYAL INSTITUTE OF PUBLIC HEALTH, Lecture Hall of the Institute, 37, Russell-square, W.C. 1.

Course of Lectures and Discussions on Public Health Problems under War and After-war Conditions:—

WEDNESDAY.—4 P.M., Lecture VII.:—Dr. A. E. Shipley: Health and Insect Life in War and Peace. Followed by a discussion.

The following journals, magazines, &c. have been received:—Cleveland Medical Journal, Duodecim, British Dental Journal, Military Surgeon, British Journal of Dental Science, British Journal of Surgery, Annales de Médecine, Hospital Gazette, American Journal of Medical Sciences, Interstate Medical Journal, Medical Officer, Therapeutic Gazette, Archives of Pediatrics, Medical Journal of South Africa, Medical Times.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.*

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C. 2.

MANAGER'S NOTICES.

ALTERATION IN THE PRICE OF "THE LANCET."

INCREASED war expenses and cost of production necessitate an increase of the price of THE LANCET. Commencing with the new year, the price was raised to 8*d*. The rates of subscription remain as revised in October.

INLAND.

One Year	... £1 10 0
Six Months	... 0 16 0
Three Months	... 0 8 0

COLONIES and ABROAD.

One Year	... £1 12 6
Six Months	... 0 17 6
Three Months	... 0 8 9

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C. 2.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C. 2, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION is published in time to catch the weekly Friday mails to all parts of the world.

Goulstonian Lectures
ON
PARATYPHOID INFECTIONS.

Delivered before the Royal College of Physicians of London.

BY CHARLES HEWITT MILLER,
M.D. CAMB., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN, LONDON HOSPITAL; PHYSICIAN, VICTORIA HOSPITAL FOR CHILDREN; LATE MAJOR (TEMP.), R.A.M.C.

LECTURE II.*

II. THE DYSENTERIC TYPE.

THE term dysentery is apt to be too freely used for conditions in which a painful diarrhœa is the chief symptom. It should be limited clinically to those cases in which there is a frequent passage of blood and mucus accompanied by pain and tenesmus.

Can the Paratyphoid Organisms cause Dysentery?

The first point to be discussed is whether the paratyphoid organisms can cause dysentery. There have been hundreds of cases of dysentery, many of them from Gallipoli, whose stools yielded only the paratyphoid organisms in England.

Of the 310 cases from Gallipoli in my series 70 gave a history of dysentery; this is probably too low an estimate, as mild dysentery may have occurred and been overlooked by the patient. In very few of these cases was evidence of amœbic infection found.

It is beyond doubt that a very great number of amœbic infections occurred at Gallipoli, particularly in the months of July, August, September, and October. In November bacillary dysentery became more common, the Shiga bacillus being more frequently found than the Flexner.[1] Of the 70 cases of dysentery with paratyphoid stools that came under my notice, 58 of them began to be ill in the period of July to October—the amœbic period.

Lieutenant G. B. Bartlett, R.A.M.C., has kindly shown me the results of his post-mortem investigations on cases of the mixed condition of amœbiasis and infection by the paratyphoid organisms. His cases demonstrate that—

1. Amœbic ulceration of the colon may be present without there being any symptoms of dysentery. It was discovered post mortem in a patient who died from enteric fever due to *B. paratyphosus B* in whom there had been no symptoms of dysentery.
2. Signs of amœbic dysentery may begin in the stage of convalescence after paratyphoid fever.
3. The patient may be admitted to hospital suffering from amœbic dysentery and may develop the additional condition of paratyphoid fever.

Mixed infections of this sort were undoubtedly common; the mortality from them was low so that opportunities for proving the condition post mortem were few.

Bartlett's conclusions are based on post-mortem examinations, macroscopic and microscopic, and on examination of the stools during life. Amœbiasis of the colon may be present without giving rise to any symptoms. It is possible that the symptoms may be begun and kept up by secondary infections such as the paratyphoids.

On the other hand, there is no doubt that the enteric organisms do attack the large intestine. Ulceration of the large intestine in typhoid fever is found post mortem more frequently than is thought. It is stated by many observers, and, in my opinion, correctly, that the paratyphoid organisms are even more prone to select the large intestine for attack.

Torrens and Whittington[2] regard the affinity of *B. paratyphosus B* for the large intestine as a point in differential diagnosis.[3] French observers have noted inflammation and ulceration of the large intestine in paratyphoid fevers A and B.

Dawson and Whittington,[2] in reporting cases of autopsies on paratyphoid patients who died in France, describe 10 cases out of a series of 17 in whom the large intestine was inflamed or ulcerated. The 10 cases were all infections by *B. paratyphosus B*. "In the milder examples the lymphoid nodules were raised, hyperæmic and umbilicated, whereas in the severer forms there were ulcers of varying sizes and depths, the ulceration being most marked in the cæcum and colon as far as the splenic flexure. Notwithstanding the marked distribution of ulcers in the large intestine, it is noteworthy that there were no clinical manifestations of it."

Rathery and his colleagues describe three forms of colitis due to paratyphoid B: (1) Colitis with small ulcers; (2) perforating ulcerative colitis with large deep ulcers; (3) proliferating ulcerative colitis. There are post-mortem findings, and there was apparently no sign of amœbiasis.

As a result of post-mortem evidence it would seem that there can be ulceration of the colon caused by amœbæ or paratyphoid organisms without any symptoms of dysentery having been present; and that dysenteric ulceration may be caused either by amœbæ or by paratyphoids A and B. But it is doubtful whether the question is capable of so simple an answer.

In many cases of paratyphoid dysentery where neither amœbæ nor amœbic cysts have been found in the stools, it is not justifiable to attribute the dysenteric symptoms to paratyphoid organisms alone. These cases may have been amœbic in origin. The evidence of amœbiasis may have disappeared under treatment, or the technical difficulties of finding amœbæ or cysts may have been too great. With improved methods of search amœbic cysts are being found more often than before.

Wenyon and O'Connor[4] state that although amœbic dysentery was rife at Gallipoli during the summer months, bacillary dysentery was more common than is generally thought, and that "there has been a tendency to overestimate the amount of amœbic dysentery on the peninsula during the summer months of 1915, though they recognise that this disease was an important factor in the invaliding of our troops from this section of the Mediterranean."

Rajchman and Western[5] have issued an exhaustive report upon 878 cases of bacillary enteritis received from the Eastern Mediterranean. The patients were in the convalescent stage, but in spite of this the authors have been able to collect most valuable and conclusive evidence. Their results show that the epidemic of dysentery in our Mediterranean force was very complicated. "Both amœbic and bacillary cases existed side by side or actually in the same individual, while a number of cases were not those of dysentery proper so-called, but of paratyphoid fever, of which both varieties A and B were found; but typhoid fever did not play a rôle in the epidemic." Where the bacterial infection was mixed they found that the dysentery bacilli were the originally infecting virus. The two forms of bacillary dysentery (Shiga and Flexner) were found by them in some cases in a pure state, in others they were mixed with other infecting agents, such as the paratyphoid bacilli.

Considering the question in the light of recent work and of clinical observations the following conclusions may be stated:—

1. Paratyphoid fever A and B can begin with symptoms that can justifiably be called dysentery.
2. The paratyphoid organisms, especially A, may be found in the stools of patients who are suffering from dysentery which was originated either by protozoa or the *Bacilli dysenteriæ*.
3. The usually accepted causative agents of dysentery, protozoal and bacillary, may be present in the stools without the patient having had an attack of dysentery.
4. The problem is one practically confined to our forces in the Mediterranean area where multiple infections are common.

Part of the difficulties arise from the vagueness of terms. The word dysentery is only a name, and it is sometimes given by the patient himself to his condition. Once he is labelled with the diagnosis, he may go far through his hospital career before it is found that he is not infected with any of the recognised causes of dysentery but with something else.

Nomenclature is a troublesome matter for the would-be reformer, and I do not put forward my suggestions as perfect; but I should like to see some such classification as this in general use.

When the signs and symptoms point to enteric fever, let the condition be called enteric fever, and the letters T, A, or B added later as laboratory investigations are made.

When the signs and symptoms point to entero-colitis and the cause is not protozoal, the term bacillary entero-colitis could be used. (The abbreviation B.E.C. would be

quite at home with V.D.H., I.C.T., &c.) The distinguishing letters S, F, A, B, and T, if it were needed, could be added as the infecting bacillus was discovered.

Cases of Dysentery with Paratyphoid Organisms in Stools.

The following two cases are examples of dysentery, in one of which *B. paratyphosus A* and *B* were found in the stools, and in the other both paratyphoids and *B. dysenteriæ* (Shiga) in addition.

CASE 3.—A. W., inoculated against typhoid four months before; admitted in October, 1915, from Gallipoli. He had been ill for six weeks with dysentery; treated with emetine, bismuth, and castor-oil. On admission T. 101° F; he was emaciated, blue, cold, and collapsed, his mind was wandering, and he was moaning and could with difficulty be made to answer questions. Pulse just perceptible; throat and mouth ulcerated and covered with patches of membrane; abdomen retracted, tender and gurgling on palpation; skin covered with cyanotic petechial hæmorrhages. No control over rectum and bladder. There was a constant passage of small quantities of pink mucus with an occasional trace of fæcal matter and much preliminary griping. *B. paratyphosus A* and *B* both isolated from stools; no agglutination to any member of enteric and dysenteric groups on any examination.

This is a severe but typical example of many cases. As he recovered no further investigation was made. But whether this was originally a case of dysentery with a secondary infection by the paratyphoids cannot be known. It is interesting to note that another man who was admitted at the same time in exactly the same condition was infected with *B. dysenteriæ* (Shiga).

CASE 4.—S. T., inoculated twice against typhoid October, 1914. He went sick in November, 1915, with dysentery, diarrhœa, and passing blood; treated with emetine. Admitted Jan. 8th, 1916; frequent offensive stools with persistent blood; improved for some months, but in April and May was slowly losing ground. May 20th: Examination by sigmoidoscope revealed extreme ulceration; irregular ulcers were seen lying transversely with bridges and islands of mucous membrane, and coming down to within 4 inches of the rectum. June 3rd: Operation. Ileo-sigmoidostomy and enterostomy; definite improvement for a week. June 18th: T. rising; very ill. June 20th: Perforation of fæcum 4 inches above artificial ileo-sigmoid junction; general peritonitis; operation; suture; death. There was dysenteric ulceration of colon and ulceration of Peyer's patches of enteric type seen at operation; one ulcer had perforated. No P.M.

In this case there was bacteriological evidence of bacillary dysentery and of both paratyphoids. Pathologically there was ulceration of the colon, and ulceration of Peyer's patches. That is, there was a double infection, and evidence of two kinds of disease of the intestinal tract. To what extent, if any, these pathogenic organisms interacted is a matter for speculation.

From the purely clinical point of view the matter is not so complex. The patients have dysentery and they have paratyphoid organisms in their stools. Both the symptoms and the organisms have to be overcome.

There are no particular clinical features about these patients with paratyphoid dysentery. There are pain, tenesmus, and straining; the passage of blood and mucus; the extreme weakness and emaciation that are seen in all severe forms of dysentery.

The stools in amœbic dysentery consist of dark blood and mucus rather than of bright red blood and pink mucus. In bacillary dysentery the blood is brighter and is in streaks in the mucus, or the mucus is pink. In this form there is often a history of an initial fæcal diarrhœa which empties the intestine and is succeeded by the passage of blood and mucus. I mention these points with reserve, for my experience of dysenteric stools is not sufficiently extensive to justify a dogmatic statement.

In these cases of paratyphoid dysentery there are occasionally symptoms, as in the last case quoted, that indicate a more definite and specific infection by the paratyphoid bacilli, such as an exacerbation of the illness accompanied by a rise of temperature, headache, a crop of spots, and an enlarged spleen; in other cases jaundice has supervened.

Progress with these patients is very slow, and it is difficult to establish control over the sphincter and to obtain regularity of the bowels. Temporary relapses of a minor character are very common and may be brought on by a sudden change of the weather, particularly a cold east wind, and by indiscretions of diet.

A troublesome feature in some cases has been an intermittent spasm of the sigmoid. The patient is conscious of the periodic formation of a painful tender lump in the left iliac fossa which can be felt as a sausage-shaped tumour. Examination with the sigmoidoscope reveals the spasm very clearly.

III. THE BILIARY TYPE.

According to some observers, the infection of the bile-passages and gall-bladder by paratyphoid organisms has been very frequent; according to others it has been rare.

Thus Sarrailhé and Clunet[6] write of the frequency of camp jaundice at Gallipoli. They isolated from the blood a particular strain of paratyphoid organism which was present at the time of the incidence of the jaundice. This organism failed to give definite reactions with specific sera and was therefore not classified. They named it provisionally paratyphoid D (Dardanellensis), and it has since been proved in a large majority of the cases to be paratyphoid A.

This jaundice began to be prevalent in the middle of August. It occurred "among tired troops confined for several weeks in a restricted space and tried by imperfect feeding and unfavourable climatic conditions." Jaundice occurred either as a sequel to a febrile gastric derangement or as a feature of a febrile attack. In the latter there was great weakness, loss of appetite; there was no itching of the skin; convalescence was prolonged.

Jaundice was very prevalent at one time at Gallipoli, and some of the patients did not feel ill enough to report sick. These were to be seen working with the appearance of jaundice well marked, as has been reported by Dudgeon.[7] Rathery, however, comments on the rarity of jaundice and biliary complications among the 1088 patients in his series of *paratyphoid B. infections* occurring in Flanders.

Among the cases of my series jaundice of the catarrhal type has been seen—

1. Quite early in the illness; more often it appears after a period of malaise. It resembles a simple catarrhal jaundice in character and is seldom severe or troublesome.
2. It can appear later in the illness; it has been seen on several occasions during the unsatisfactory stage of convalescence when the temperature is not steady. It is of the catarrhal type in these cases, but is rather more severe and lasting in the latter.
3. It has a tendency to become recurrent. After the patient has had a mild attack of jaundice and has quite recovered and been in good health for months the jaundice may return and be much more severe than in the original attack.

CASE 5.—An officer, in Gallipoli from start to finish, was never really ill there, but had indigestion, slight jaundice, and dysentery. A year later, in France, he was suddenly taken ill with gastric discomfort and vomiting; jaundice set in and became very deep. Liver and spleen enlarged; occasionally slight tenderness over gall-bladder region; great itching of skin and recurrent attacks of urticaria: P. 68. *B. paratyphosus A* in stools. Jaundice lasted 10 weeks, but patient was feeling quite well long before colour had disappeared from skin.

Cholecystitis may occur and may be accompanied or not by jaundice.

Several cases of acute cholecystitis without jaundice have been seen. In most of those that I have seen there has been a transitory tinge of the conjunctivæ and a darkening of the urine, sufficient for the patient to notice it. Acute cholecystitis with severe jaundice has also been noticed, but in some of the cases there was an empyema of the gall-bladder.

Morley and Battinson Smith[8] have described an unusual case of acute gangrenous cholecystitis with spreading peritonitis occurring in the epidemic of jaundice in Gallipoli. Campbell isolated *B. paratyphosus B* from the bile and stools of this patient.

The following case throws an interesting light on the possible sequels of paratyphoid infections of the biliary tract.

CASE 6.—Army pensioner admitted to hospital for recurrent attacks of pain and jaundice; had very severe attack of enteric fever in Boer War. In 1904 two attacks of colic and jaundice. He was free from attacks for 11 years from 1904 to 1915. From August, 1915, to April, 1916, he had 12 attacks beginning with shivering, vomiting, and pain of varying intensity. The stools at once became light in colour and the urine dark. The jaundice lasted 4 to 14 days. Edge of liver palpable and gall-bladder just felt. At operation gall-bladder was found to be inflamed, adherent, and friable; it contained a few gall-stones. *B. paratyphosus B* isolated from bile.

This case and the previous one illustrate two different clinical forms of jaundice occurring late in the course of a paratyphoid infection; for it is reasonable to infer that in the first case the paratyphoid infection occurred at Gallipoli and in the second in South Africa.

In their investigation into jaundice of infective origin in France, Dawson and Hume[9] report 26 cases of the enteric group, of which 6 were due to typhoid, 14 to paratyphoid B, 4 to paratyphoid A, 1 to a double infection of paratyphoid A and B, and 1 to an undetermined infection of the enteric group. One of these cases was fatal from acute pneumonia.

In their post-mortem reports Dawson and Whittington obtained paratyphoid bacilli from the gall-bladder on 14 occasions—13 B and 1 A. In 1 case there was increasing

[9] Dawson and Hume: Quart. Jour. Medicine, x., Nos. 37 and 38.

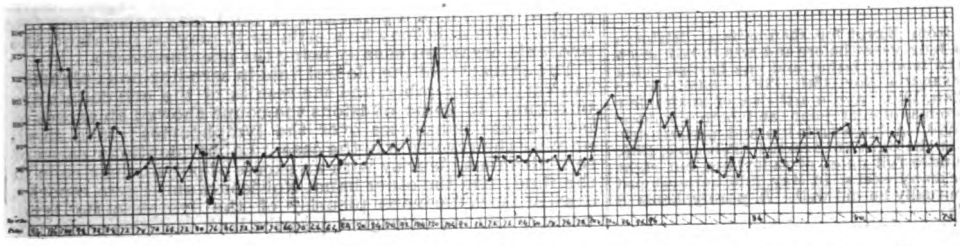
jaundice during life, and abscesses of the liver were found post mortem. In 2 cases purulent fluid was found in the gall-bladder, but in neither case was there jaundice during life.

There is no doubt that the paratyphoid organisms frequently invade the biliary system, but do not so frequently cause jaundice at the time; but there is a considerable danger of chronic cholecystitis with the formation of gall-stones being found months or years afterwards, and there is a great danger that the gall-bladder may become a reservoir of infected bile which is periodically discharged into the intestine.

IV. NEPHRITIS AND OTHER AFFECTIONS OF THE URINARY TRACT.

Albuminuria is commonly present for a few days at the height of the fever, but this hardly needs comment. But there is a very great tendency for the paratyphoid organisms to find their way into the urinary tract. In several cases the organisms can be found in the urine both in the acute stage and afterwards for a varying length of time without there being any evidence of infection of the urinary tract.

Nephritis.



Acute nephritis is fairly common; it was present in 4 per cent. of my cases. It was most commonly found in the period when "trench nephritis" was so prevalent. Possibly this figure is too low. The patients were admitted with the diagnosis of nephritis, and the paratyphoid infection was discovered later. Possibly some cases escaped detection.

There is nothing peculiar to the nephritis of paratyphoid. The cases differ in type and degree of severity in exactly the same manner as in other infective inflammations of the kidney. The results are also similar. The mild cases make an apparently good recovery, though their convalescence and period of symptoms is prolonged. The severe forms commonly pass into a chronic condition with permanent cardio-vascular changes and have to be invalided out of the service or put into the sedentary class. Whenever there was a history of previous renal disease the progress was more slow and the result unsatisfactory, and, broadly stated, men over 35 years were unfit for full service again, even if their progress had been good.

A curious condition was noticed on several occasions. Patients were admitted bearing the yellow label of "nephritis." The face, eyelids, and ankles were swollen and had been in that state for a few days. The urine was normal as regards quantity and absence of albumin. Several of these patients had paratyphoid A or B in their stools. In some of them it was noticed that the cardiac area was enlarged, the apex beat displaced outwards, and the cardiac action rapid, especially on examination. Their progress was uneventful and they were soon free of symptoms.

Moorhead[10] reports that in 5 per cent. of his cases there was retention of urine at the onset of the disease.

CHART 6 (Case 7).

Enteric fever, paratyphoid B. Prolonged irregular temperature, with two recrudescences. Acute nephritis.

The following is an example of a severe case of acute nephritis (paratyphoid B).

CASE 7.—W. D., aged 22, admitted from France, Dec. 4th, 1915, as nephritis. History: Ill four weeks; began with swelling of face; passed a lot of water at first; no headache, no sickness, no sore throat; bowels not properly open. Condition: Flushed, dry skin; tongue white; T. 103° F. (Chart 6); P. 84, dicrotic; spleen palpable; a few rose-red spots on abdomen; basal bronchitis. Urine 18 oz. in 24 hours; dark and smoky, with a brown sediment. Reaction neutral, albumin ¼; blood cells, blood casts, and epithelial casts. Treatment: Urotropine gr. x. t.d.s. Dec. 18th and Jan. 24th: Albumin a trace, pus cells, and casts. Feb. 17th: Albumin a cloud, no casts. Feb. 26th: No albumin, no casts. Brachial blood pressure, 116 mm. Hg. Bacteriological examinations: Dec. 8th, agglutination +++ to paratyphoid B; paratyphoid B isolated from stools Dec. 16th; from urine Jan. 7th, and similar results on other dates.

Progress.—The temperature came down by lysis, and though not steady was not above 99° for three weeks; then there was a recrudescence lasting six days, and one week later another recrudescence of milder character, after which progress was uninterrupted. The relapses were of the enteric type, and the urine was not affected. On discharge he was passing 50–60 oz. of normal urine per diem.

This case may be regarded as one of paratyphoid fever in which the first onslaught was felt mostly by the kidneys. As time went on the "enteric" character of the disease became more definite, and as the "enteric" relapses occurred there was no further inflammation of the kidneys.

The following case is one with vascular-renal changes.

CASE 8.—J. S., aged 40, admitted for nephritis. History: Eight weeks before had been very wet and felt generally ill afterwards. Two weeks later he got very wet again. Swelling of face, legs, and stomach noticed soon after; headache very bad. Urine almost solid with albumin; blood present in large quantity; epithelial casts. Brachial blood pressure 154 mm. Hg. Three months later albuminuric retinitis was discovered. *B. paratyphosus B* isolated from stools on several occasions.

In this case there was probably some vascular-renal deficiency of long standing. There was no "enteric" feature in the disease. It might be argued that this was a case of chronic nephritis with an accidental contamination of the stools that had nothing to do with the renal condition, but I should prefer to regard it as a case of imperfect kidneys made worse by a microbic infection.

CHART 7 (Case 9).

Enteric fever, paratyphoid A infection. Acute nephritis. Prolonged irregular temperature with some morning rises and evening falls.

The following case presents several points of interest:—

CASE 9.—H. F., aged 30, admitted April 4th, 1916, from Egypt for nephritis. History: Illness began in February with headaches, swelling of legs and feet, and fever. Temperature raised on the boat. Condition: Intense headache and photophobia; muscular twitchings; breath urinous; great emaciation. T. 102·2°, P. 76. Partial incontinence. Urine very scanty; half albumin. After two days he passed 100 oz. of urine containing a trace of albumin; this condition persisted. Rose-red spots, enlarged spleen, high temperature with inverted remissions, and slow pulse made the diagnosis of enteric fever definite. (Chart 7.) Bacteriological examinations April 7th: *B. paratyphosus A* in stools; urine sterile. He ultimately made a good recovery and on discharge was passing 70 oz. of urine free from albumin.

His condition on admission was very grave; it is difficult to say how much of it was uræmic and how much the typhoid state. It seemed to be a mixture of both conditions.

But the greater number of these patients have milder conditions. There is usually swelling of the face and legs, a small quantity of albumin in the urine, blood cells and a few epithelial casts. Isolation of paratyphoid organisms from the urine is infrequent, but the presence of the organisms in the stools and the agglutination reaction will decide the nature of the infection.

The symptoms are usually very obstinate, headache, backache, and morning puffiness of the eyes lasting a long time even after the urine is free from albumin. The majority of the younger men return to duty of some sort, but not many are fit for the trenches until they have been under care and observation for a long time.

Other urinary infections are as follows:—

Pyelitis occurs occasionally and pyonephrosis caused by *B. paratyphosus B* was seen in two cases.

Worster-Drought and Kennedy[11] have described an interesting case of acute urinary infection with paratyphoid B. There were acute vesical symptoms and pyuria. There were no signs nor symptoms of any infection of the alimentary canal.

[10] Moorhead: Med. Press and Circular, 1916.

[11] Brit. Med. Jour., May 6th, 1916.

Cystitis is one of the commonest and most lasting of the later troubles. It may occur with pyelitis or without it. At first there is pyuria and the passage of urine containing the paratyphoid organism. Later the *Bacillus coli* appears and swamps the paratyphoid bacillus. Such patients may become very obstinate and dangerous carriers.

The urinary tract seems to be very vulnerable to the paratyphoid infections, especially to *B. paratyphosus B*. It is seldom that it is possible to speak warmly about the properties of a drug, but in these infections the benefits obtained from urotropine are very striking. It is my opinion that a routine use of urotropine would be found beneficial in all paratyphoid fevers, both for prevention and cure of urinary infections.

V. THE "RHEUMATIC" TYPE.

I am using the term "rheumatism" in the popular sense, and not according to strict medical terminology. In popular usage "rheumatism" will describe all forms of inflamed painful joints and muscles.

Apart from the aching backs and legs of which so many paratyphoid patients complain, there are a number of conditions to which the term "rheumatism" can be applied. Articular rheumatism has been observed by several writers. Nobécourt and Peyre[12] say that it is a common feature in paratyphoid fevers, especially in paratyphoid B. Wiltshire has drawn attention to arthralgia and myalgia. Among my cases there was a surprising amount of "rheumatism," as many as 8 per cent. being affected in various ways.

1. Acute articular rheumatism was seen in a few cases.

The joints were hot, swollen, and painful; usually there was considerable fluid. The condition was improved by sodium salicylate in full doses. In addition to the rheumatism some of the signs of an enteric infection were present, and there was positive bacteriological evidence. In several of these cases there was a history of a previous attack of acute rheumatism.

2. A condition more closely resembling the "infective" type of arthritis was commoner.

In more than one case the suspicion of gonorrhœa was entertained before it was disproved and the presence of a paratyphoid organism discovered. In these cases the knee-joints were particularly affected. There were heat, swelling, and pain in the joints. The swelling was synovial and in the neighbouring tendons and other periarticular tissues. It was accompanied by great wasting of muscles. The results were unsatisfactory; partial ankylosis occurred in two cases, and in others the joint had to be very gently treated for a long time. There was a great tendency for the joints to swell again with the least strain on them.

Many of these joints had previously been damaged at foot-ball and they became acutely inflamed during paratyphoid fever.

In others the patients came under observation on account of their joints and were found to be infected with paratyphoid organisms.

The following two cases are illustrations of these two conditions. Also both suffered from acute iritis in the later stages of the disease.

CASE 10.—L. H., admitted from Egypt for rheumatism. History: He had swollen painful joints four years before and was in bed seven weeks. Rheumatism is in the family, father and one brother being subjects. He landed at Alexandria Nov. 15th, 1915. Admitted to hospital for dysentery Dec. 25th, 1915. Acute arthritis of ankles, left knee, left wrist, left temporo-mandibular joint, and both shoulder joints set in on Jan. 7th, 1916. A large arthritic and periarthritic effusion developed in and about the right knee early in February, 1916. The other joints cleared up under full doses of salicylates, but right knee remained *in statu quo* for many weeks. In May, 1916, he developed acute iritis of left eye. Eventually he did well. *B. paratyphosus B* repeatedly isolated from stools.

CASE 11.—J. B., admitted from Mediterranean for bronchitis and emphysema. On admission both knee-joints swollen and painful; swelling fusiform. Fluid in joints and tissues above and below joint. Later he developed double conjunctivitis and iritis. He did not respond to salicylates. *B. paratyphosus A* repeatedly isolated from stools.

3. There is a group of cases which, for want of a better term, I have called the "trench-fever type." This group can for convenience be described under the heading of "rheumatism."

Before there were such complete and detailed accounts of "trench fever" I had noted that occasionally painful, tender shins, worse at night, were symptoms of a mild type of paratyphoid fever. The onset in these cases was sudden; the temperature was usually not as high as 103° F. They were not seen at all frequently until April, 1916. They came into hospital with the diagnosis of "trench fever," and they closely resemble it. They were found bacteriologically to be paratyphoids. On the other hand, the majority of the "trench fever" patients gave no bacteriological evidence of being paratyphoids. The following cases are examples:—

CASE 12.—J. P., admitted June 15th, 1916. Labelled "typical trench fever, T. 102·4°." Inoculations: typhoid, two, October, 1914; T.A.B., two, May, 1916. History: On June 1st sudden onset of shivering, headache and legs aching. Temperature, June 15th, normal; shins still tender and painful at night. *B. paratyphosus B* repeatedly isolated from stools.

CASE 13.—W. S., admitted as trench fever May 24th, 1916. In hospital since April 17th. Has fever every five days; aching shins very bad at night. *B. paratyphosus B* isolated from stools.

CASE 14.—F. C. S. admitted as "trench fever" August 27th, 1916. Inoculations: Typhoid, two, June, 1915; T.A.B. two, April, 1916. History: Went sick two weeks before; had fainted twice on the march. He complained of pain in back and legs and bad headache. Condition: T. 102·2°, P. 100; tongue dry, shins very tender; internal saphenous veins thrombosed over the malleolus; abdomen firm; some possible spots, fading; drowsy. *B. paratyphosus A* isolated from stools.

The last case was more definitely of a clinically enteric type. I quote these cases to show that the syndrome of trench fever may be associated with a paratyphoid infection. Though relatively only a few cases of trench fever will yield evidence of paratyphoid infection, it is important to exclude paratyphoid in the cases which present the "trench fever" group of symptoms. For there is evidence to show that the two diseases can easily be confused, and it takes time and repeated examinations to distinguish them. This type of paratyphoid fever did not come under my notice in the early months of the war, nor did I see any in cases from Gallipoli. I am at a loss to explain why this should appear in the spring of 1916 and after. The number of cases is too limited for any theory to be put forward, but it is worthy of note that the nature of paratyphoid fever has changed entirely since the triple vaccination became general. Further than that it is impossible to go.

VI. DISEASES OF THE RESPIRATORY TRACT, BRONCHITIS, PLEURISY, AND PNEUMONIA.

Infections of the respiratory tract are common. In fact, Labbé regards them as the only complications that are specific to paratyphoid fever.

Bronchitis is very commonly present.

Usually it is only a mild condition, but there may be general bronchitis of a severe type. Minet[13] describes 8 cases of severe bronchitis occurring as the first evidence of the disease; of these 6 were paratyphoid B and 2 were paratyphoid A. Other observers have made similar records.

The onset in these cases is sudden, often with a rigor, and the patient is more ill than the physical signs in the chest would indicate. In a few days the clinical features of enteric fever and the bacteriological tests will settle the diagnosis.

Pleurisy is far from uncommon in paratyphoid fever.

It may be quite trivial and pass away in a few days or it may be the starting-point or accompaniment of pneumonia. A very acute pleuro-pneumonia may follow rapidly on a pleural friction, or a collection of fluid may appear in a few hours. The fluid may be sterile or it may be purulent, the pyogenic organism usually being the pneumococcus.

The character of the pleural fluid in sero-fibrinous pleurisy can vary considerably, and the results of the cell counts are puzzling. In some effusions the count showed an excess of polynuclear leucocytes over the lymphocytes; in a small number the reverse was the case. Labbé mentions cases of sero-fibrinous pleurisy with an excess of polynuclear cells in the fluid. On the other hand, Nobécourt and Peyre report a case of sero-fibrinous pleurisy of the lymphocytic type. Rathery and his colleagues describe both varieties occurring in paratyphoid B fever, but in their one case of lymphocytic pleural effusion there was a history of death from tuberculous meningitis 7½ months later.

When organisms are isolated from the pleural fluid they are found to be of the pyogenic varieties, most commonly the pneumococcus, and the effusion becomes purulent.

The two cases described below illustrate the features of the lymphocytic pleural effusions. The relationship between paratyphoid infections and possible tuberculosis will be considered later.

CASE 15.—A.S., admitted for pneumonia. The illness started with a rigor. On admission pleural friction with impaired resonance and diminished breath sounds at right base and axilla. In 48 hours signs of fluid very definite and heart displaced outwards. Clear fluid was withdrawn by aspiration, which was sterile and showed a large excess of lymphocytes. *B. paratyphosus B* repeatedly isolated from stools.

[12] Nobécourt et Peyre: Bull. et Mém. de Soc. Méd. des Hôpitaux de Paris, 1916, iii. S., xl.

[13] Minet: Bull. et Mém. de Soc. Méd. des Hôpitaux de Paris, 1915, iii. S., xxxix.

There was nothing in the history, the signs, or the subsequent course to suggest the presence of tuberculosis.

CASE 16.—E. R., admitted for dysentery, from which he was convalescent. The day before admission he had pain in right side and shivering. He was cold, blue, and collapsed. The signs were those of pleurisy and consolidation of right lowest lobe. In three days there was a large effusion which was aspirated then and on three subsequent occasions. He ultimately did well.

The fluid on all occasions was clear, sterile, and showed an excess of lymphocytes. No tubercle bacilli found in sputum but radiogram showed opaque glands at roots of lungs with radiating bands of fibrous tissue in lung. *B. paratyphosus A* present in stools.

As has been mentioned, a pneumococcal empyema may occur during paratyphoid fever. The following case is an example, and it further illustrates a condition of partial consolidation of the upper lobe, which gives rise to signs similar to those of pulmonary tuberculosis.

CASE 17.—C. B., admitted with diagnosis "pulmonary tuberculosis." Illness began in France with broncho-pneumonia Feb. 25th, 1916. Admitted March 16th, 1916. The signs were those of dry pleurisy over right lowest lobe. Upper lobes on both sides, back and front, presented signs suggestive of pulmonary tuberculosis. Percussion note impaired; tactile vocal fremitus increased; breath sounds high-pitched, with lengthened expiration; vocal resonance increased in pitch and intensity, and whispered voice was conducted outside bronchial area. In addition fine râles heard both front and back. A pneumococcal empyema developed and was treated surgically. Several small crops of spots occurred at different times; spleen palpable. *B. paratyphosus A* and *B* isolated from stools.

Repeated examinations of the sputum for tubercle bacilli were negative. After the empyema had been drained the signs in the upper lobes passed off and on discharge it was impossible to detect anything abnormal. He left the hospital looking the picture of health.

Lobar and *broncho-pneumonia* are seen in paratyphoid fever.

They are seen either as the initial condition or occurring at any time in the course of the disease. In any case the occurrence of pneumonia is a very serious feature, and the prognosis is bad. There is a tendency for broncho-pneumonia to be of the "creeping" variety. As one consolidated area begins to resolve a neighbouring unaffected area becomes solid. In some of these cases hyperpyrexia has been seen and commonly very excessive sweating occurs.

In a case recently seen left basal pleuro-pneumonia began with a rigor and an attack of diarrhœa. Gradually, catarrhal signs and signs of consolidation spread over both lungs. After eight days diarrhœa started again; spots of the paratyphoid variety came out on the abdomen, and the spleen was palpable. The temperature was above 104° F. for two weeks, and gradually rose to 107°, when the patient died.

The paratyphoid bacilli apparently do not attack the lungs and pleura themselves. Labbé, however, mentions a case of abscess of the lung, from the pus of which *B. paratyphosus B* was isolated. Apart from this rather special case, I cannot find a recorded instance of paratyphoid bacilli being found in pleural fluid ante mortem, nor in the lungs post mortem. I can only think that if these organisms do attack the lungs and pleura it must be but rarely.

It is interesting to note that many patients suffering from wounds of the chest and hæmothorax became infected with paratyphoid organisms. These wounds were important predisposing factors.

The relationship of paratyphoid infections to *tuberculosis* has been mentioned in the descriptions of the last three cases.

If a lymphocytic pleural effusion is to be regarded as a sign of tuberculosis and of nothing else, it would appear from the consideration of my cases and those described by others, that the power of paratyphoid infections to activate latent tuberculosis is great. Rathery's one case in which a fatal termination was due to tuberculous meningitis is very suggestive.

In the second of my cases described I have a strong suspicion that there was underlying tuberculosis. In the other case, however, there was no indication of tuberculosis. I am, however, inclined to the opinion that the lymphocytic effusions which have been seen in paratyphoid affections are really evidence of tuberculosis stirred to activity by the paratyphoid infection.

Pulmonary tuberculosis may reveal itself during the acute stage of paratyphoid fever. More commonly it occurs during the stage of convalescence. In such patients there may be a history of some former chest trouble which would cause a suspicion of tuberculosis.

On the other hand, there may be well-grounded suspicion of pulmonary tuberculosis, which events fail to prove, as in the case of empyema just quoted. In that case I was convinced for some days that there was pulmonary tuberculosis, but eventually the diagnosis had to be given up. I learn with interest that Rathery and his colleagues had difficulties of the same kind, and in the end gave up the diagnosis of pulmonary tuberculosis on the signs found in the upper lobes in these cases.

The paratyphoid organisms can also rouse latent tuberculosis in other parts of the body. During convalescence from a mild attack of paratyphoid A fever one patient developed a rapidly progressive tuberculous peritonitis, which was arrested only after prolonged treatment.

VII. THE INFLUENZAL TYPE.

Influenza and paratyphoid fever have much in common. Not only do both diseases appear in divers forms, but paratyphoid fever can imitate the forms of influenza so closely that at the onset of the fever it may be impossible to distinguish between the two conditions. Later, in the course of paratyphoid fever, we may expect to find some of the signs that point to an enteric infection, but they do not always appear, and the diagnosis is made by the bacteriologist on nothing more than the suspicions of the clinician.

Paratyphoid fever may simulate three different forms of influenza.

1. *Respiratory form.*—The onset is sudden with rhinitis, pharyngitis, and often laryngitis. The catarrhal condition may travel downwards and affect the trachea and bronchi. There is a moderate amount of fever and a slow pulse; frequently there is copious sweating. Towards the end of the first week more definite indications of enteric fever may be present. Stolkind lays stress on the prevalence of this form of infection, and undoubtedly there are plenty of examples to be seen.

2. *The gastro-intestinal form.*—In this variety the onset is sudden and accompanied by nausea, vomiting, abdominal pain, and diarrhœa. The condition of the patient may be very serious and fatal cases are reported. In time the characteristics of enteric fever may appear and the real cause of the condition can be investigated. Post-mortem examinations in such cases have revealed an intense gastro-intestinal inflammation without ulceration of lymphatic tissue.

3. *The nervous influenzal form* also occurs but is uncommon. As in the others, the onset is sudden with intense headache, irritability, and depression. In one patient who began with these symptoms, paratyphoid A and B organisms were found in the stools. Later he had a relapse which was purely of the enteric fever type.

These influenzal conditions are not likely to be suspected of being paratyphoid conditions, unless there are a good many known paratyphoid patients under observation at the same time. An individual case of this kind would probably escape detection unless the symptoms became very suggestive of enteric fever. But when one hears of small epidemics of gastro-intestinal influenza occurring in a town the suspicion should always arise concerning the nature of the infection, and it is highly desirable that paratyphoid infections should be proved or excluded. Most important of all, the manner of the origin and spread of the infection should be determined.

VIII. THE SEPTICÆMIC TYPE.

There is little to be said of this type.

It is seen most commonly in patients who die early in the disease. Post mortem no local lesions are found, but only the signs of an acute septicæmia. In some of the most virulent cases gangrene of the extremities sets in and progresses rapidly until the patient dies.

Job and Ballet describe three cases of death from paratyphoid fever (2 A, 1 B), in which the post-mortem findings were not distinctive of anything but septicæmia. Sawasaki also describes similar cases occurring in Japan.

VARIED CLINICAL MANIFESTATIONS OF PARATYPHOID INFECTIONS.

This concludes my description of the various clinical types of paratyphoid fever. It would not be difficult to add other varieties, and if, as is probable, I have omitted some forms that have occurred in the experience of other observers, I wish it to be remembered that this account, faulty and inadequate as it is, is only the account of what I personally have seen. It can be added later to the accounts given by others to help in making up the sum total of our clinical knowledge of paratyphoid fever.

It is obvious that the paratyphoid organisms can be protean in their clinical appearances. Paratyphoid fever may be regarded as a great imitator of other diseases. It may be like typhoid fever, like dysentery, like influenza, &c. But that is hardly the logical way of looking at it. It can cause infections and inflammations of so many systems of the

body that it is bound to resemble at one time this, and at another time another infective disease which we have come to regard as having a special morbid affinity for a particular system of the body.

Further, it has the quality in certain individuals of being able to call into activity diseases which were lying latent. Thus examples of rheumatic fever in the rheumatic subject, consumption in the patient who has arrested tuberculosis can be found in plenty. The relationship to malaria is peculiarly close. It is well known that any pyrexial condition occurring in the malarial subject will make the patient behave in the malarial fashion to a certain extent. But paratyphoid fever will bring on an attack that is malarial exactly. Further, the manner of onset in some cases of paratyphoid fever is very difficult to distinguish at first from malaria on clinical grounds.

There is a danger, that is clear to all, in such an examination as this that an obsession of paratyphoid infection might occupy the mind to the exclusion of all sense of proportion. I trust that I have steered clear of this danger in describing these forms of paratyphoid infections. But I do wish to emphasise my opinion that the infections by paratyphoid organisms are very widespread and may take a very great number of forms. It is not necessary to suspect paratyphoid fever in every case of unexplained pyrexia unless there are some definite clinical reasons for doing so. On the other hand, it is obvious that the question of paratyphoid infections will have to be considered much more seriously in the future than in the past, when epidemics of influenza and gastro-intestinal catarrh occur.

The infectivity of paratyphoid fever is very great and the amount of infecting material will certainly increase. It will be necessary for the strictest hygienic rules to be enforced in dealing with known cases, but as all the infective cases cannot possibly be known it is incumbent upon the community to protect itself by inoculation. But I can refer to this subject more conveniently later.

THE LEUCOCYTES IN CASES OF IRRITABLE HEART.

BY GRACE BRISCOE, M.B., B.S. LOND.

(A Report to the Medical Research Committee.)

THIS investigation was undertaken with the object of determining what changes, if any, are present in the white blood cells in cases of "irritable heart." All the patients investigated were soldiers admitted to the Mount Vernon Military Hospital suffering from the symptoms associated with the above condition—viz., breathlessness or palpitation on slight exertion, faintness, giddiness, præcordial pain, and general lassitude. Preliminary counts had shown that in some cases the number of non-granular cells in the capillary blood was considerably greater than normal both absolutely and relatively to the granular cells. Further investigation was undertaken to decide if this change was constant, and if it could be regarded as of value in diagnosis and prognosis.

The blood was obtained from the ear. The lobe of the ear was washed in absolute alcohol, the first drop of blood wiped away, the second drop which oozed out was used to make the film for the differential count. Blood was then taken for the total leucocyte count, Thoma's hæmocytometer being used. Acetic acid 0·5 per cent. with methyl green was employed as a diluent. An average of 400 to 500 cells was counted. For the differential count dried films were stained either by Leishman's or Giemsa's methods. A wet method described in the addendum was also employed.

The differential count.—The classification given by Cabot in Osler and McCrae's "System of Medicine," 1915, was followed. Granular cells: 1. Finely granular neutrophil cells or polymorphonuclears. 2. Coarsely granular cells or eosinophils. 3. Basophils or mast cells. Non-granular cells: 4. Lymphocytes. The large and small forms were counted separately, but in the tables only the total numbers of lymphocytes are given. 5. Large mononuclear cells.

There was some difficulty in distinguishing between the last two classes. The first counts from these patients showed a large number of cells which possessed a deeply indented nucleus, but the protoplasm was not relatively abundant, and "azur granules" were present in many cases. These cells amounted at times to more than half the total number of non-granular cells, and seemed to form a transitional class between the large lymphocytes and the large mononuclear or "hyaline" cells. The rule was adopted of classifying such cells among the lymphocytes, even if the nucleus was deeply indented, unless the nucleus occupied an area less than half of the cell. With this method of classification the count of large mononuclear cells fell in nearly every case within normal limits (1–4 per cent). In the wet counting method the large mononuclears are easily distinguished from the lymphocytes, and the parallel counts in dry and wet films showed approximately the same percentages.

(b) The margin of error.—The probable margin of error in the differential count is noticed further in the addendum. The importance of this will be seen later when the question of diagnosis is discussed. In a differential count of 400 cells the probable margin of error is considered to be 4 per cent. For the purpose of diagnosis a rise or fall of more than 8 per cent. in the lymphocyte count (400 cells counted) in blood taken at different times is considered to be outside the probable margin of error, and to indicate a real change in the proportions of the white cells circulating in the peripheral blood.

Comparison of variability of total and differential counts in cases of "irritable heart" with those of controls.—(a) *Total leucocyte counts.*—The total number of leucocytes in these cases is considerably higher than in normal individuals.

Ninety-three counts were carried out on 34 patients and 32 counts on 9 controls. The controls consisted of 3 medical men, 3 patients who had been sent to the hospital, but did not show any symptoms of "irritable heart," and 3 women. The times at which the counts were made were approximately the same, both in the case of patients and controls—viz., between 10 and 12 in the morning. Counts taken immediately after exercise are included in both sets.

Table I. is a general statement of all the counts made in patients and controls. The figure in each division of Column A represents the number of total counts which fell within certain limits, the letters in Column B the patients or controls on whom these counts were carried out, each letter representing a patient or control—e.g., of the counts which fell between 17,000 and 18,000 per c.mm., two were carried out on Patient I and one each on Patients M and R.

23,000	1	J	—	—
24,000	—	—	—	—
—	93 counts.	34 patients.	32 counts.	9 individuals.

The average total count of the patients was 12,100 cells per c.mm. (lowest 6800, highest 23,800). The average of the controls was 7400 per c.mm. (lowest 5000, highest 10,040).

The degree of leucocytosis in these patients appears to be directly proportional to the amount of exercise taken before the count is made, other factors, such as food, being the same. Of 38 counts made while the patient was in bed or after he had been lying on his bed for an hour, the average was 10,600 per c.mm. (lowest 6800, highest 16,800). Of 31 counts on these patients walking about in the ordinary way, the average was 12,700 per c.mm. (lowest 7100, highest 18,200). Of 17 counts made immediately after a staircase exercise, the average was 15,000 per c.mm. (lowest 8700, highest 23,800). In 7 controls the average count after rest was 7100 per c.mm. (lowest 5700, highest 8400); the average after a staircase exercise was 8200 per c.mm. (lowest 6200, highest 10,040).

(b) *The differential count.*—The diurnal variation of the leucocytes, even in normal individuals, is considerable. It has been ascribed to such factors as fatigue, exercise, food, &c. The time of day, therefore, at which a differential count is made becomes important.

Four-hourly differential counts showed that the diurnal variation in cases of "irritable heart" is greater than in normal individuals and that a high lymphocyte count is very common. Differences of over 20 per cent. in the lymphocyte counts in the four-hourly intervals were frequently met with. Table II. is a general statement of the polynuclear percentages in the differential counts made on the first 50 patients examined and of 73 counts on 12 controls. The controls were 4 medical men, 4 soldier patients with no symptoms of "irritable heart," and 4 women. All the counts are given irrespective of time, exercise, or food, both in the case of patients and controls.

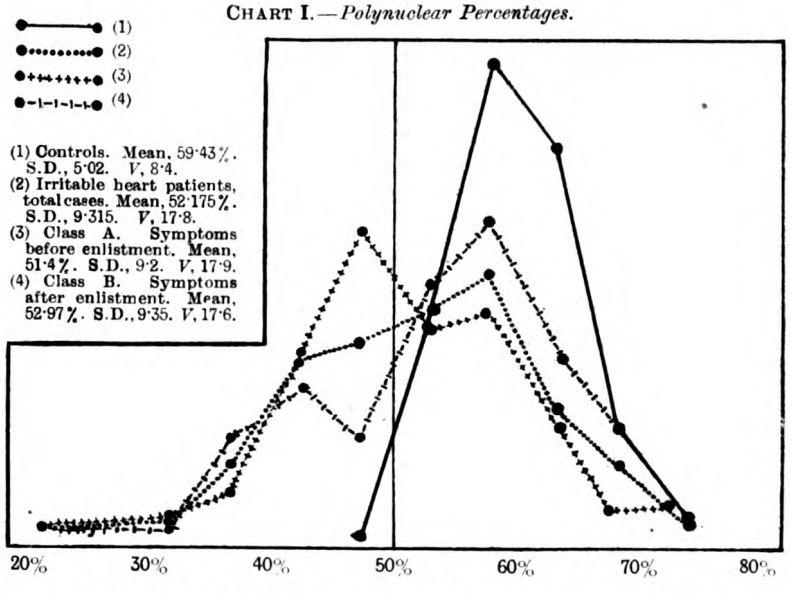

TABLE II.—*Numbers of Polynuclear Counts falling within Indicated Percentages.*

—	20%	25%	30%	35%	40%	45%	50%	55%	60%	65%	70%	Total counts.
12 controls	—	—	—	—	—	1	12	23	23	7	2	73
50 patients	2	—	5	16	36	41	47	55	28	16	5	251
Class A—25 patients	1	—	3	6	20	31	22	24	12	4	5	128
Class B—25 patients	1	—	2	10	16	10	25	31	16	12	—	123

In Table II. the figures in the horizontal lines indicate the number of counts in which the percentage of polynuclears fell within the percentage limits indicated by the vertical divisions. Chart I. shows the same results in a graphic form, given in percentages—e.g., 38 per cent. of the control counts fell between 55 per cent. and 60 per cent. The 50 patients may be divided clinically into two classes: (*a*) symptoms were noted prior to enlistment (such as shortness of breath and inability to play games); (*b*) symptoms developed during training or after service abroad. The third and fourth lines in Table II. and corresponding diagrams in Chart I. give the figures resulting from this classification.

The polynuclear percentages alone are given in Tables II., III., and V., partly because there is a smaller error in dealing with larger percentages, partly because there is no difficulty in the classification of the polynuclear cells. Only one case showed a moderate eosinophilia (8–14 per cent.), the basophils were always below 2 per cent., usually below 1 per cent. In the two low counts appearing in the division 20 per cent. to 25 per cent., one had an eosinophil count of 9·6 per cent. and the other of 2·5 per cent. The percentage of non-granular cells in the first was 69 and in the second 78. Therefore the polynuclear percentage may be considered a fair inverse index of the number of non-granular cells present.

CHART I.—*Polynuclear Percentages.*

It will be noted that in the controls 70 per cent. of the whole series fell between 55 per cent. and 65 per cent., and the largest number (39 per cent.) in any single division, between 55 per cent. and 60 per cent. (Only one polynuclear count in the controls fell below 50 per cent., and this occurred in a patient who had no symptoms of "irritable heart," but who had recently suffered from an attack of malaria.) In the patients, however, 41 per cent. of the counts fell between 50 per cent. and 60 per cent., and only 22 per cent. between 55 per cent. and 60 per cent. In Class A the largest number of counts (24 per cent.) fell between 45 per cent. and 50 per cent., while in Class B the largest number (25 per cent.) fell between 55 per cent. and 60 per cent.—i.e., the same division which holds the largest number of control counts.

Diurnal variation in normals and patients.—Two constant factors emerge from a study of the differential counts at different times of the day.

Both in controls and patients the polynuclear percentage is lowest between 6 and 8 A.M., and highest between 10 and 12 A.M. The average variation in both cases is about 10 per cent., but in the patients the polynuclear count is on a lower level at both times of the day, and the individual variations are much greater than in the controls. It will be noted that counts made on the same control at the same time on different days show very little variation. The controls consisted of two medical men and two women. The counts on the controls were made by four different observers, so that personal bias can be eliminated. No observations on the total count were made between 6 and 8 A.M., so that the absolute numbers at that time and at the middle of the morning cannot be compared. (Table III.)

H. G. Ward,[1] in a study of the hourly variations in the cells, found that the polynuclears were highest between 6 and 8 A.M., and lowest about midnight. On the other hand, A. G. Phear[2] states that the percentage of polynuclears is lowest in the early morning before breakfast. In ten observations on the same individual before breakfast he found an average percentage of 50 polynuclears (smallest percentage 47, largest percentage 54). The observations here recorded are in agreement with those of the last-named author.

Effect of rest in bed.—The moderate leucocytosis which these patients with "irritable heart" present when they are up and walking about, is not apparent when they are kept in bed.

Three patients who showed characteristic symptoms were put to bed for three days and then allowed to get up. The total count was estimated at 11 each morning, and differential counts were made every four hours.

Case 1 and Case 2 were kept on ordinary diet throughout. The differential count was of the same type whether in bed

or up—i.e., a low polynuclear count before breakfast, and a moderately high count at 11 in the morning.

The third case was kept on a milk diet while in bed and on ordinary diet when up. The differential count showed a steady rise in lymphocytes on the bed and milk régime,

TABLE IV.—*Total Leucocytes.*

—	In bed.			Up.	
	1st day.	2nd day.	3rd day.	1st day.	2nd day.
Case 1 ...	12,600	10,000	8,700	17,900	17,200
Case 2 ...	11,800	9,100	10,600	16,200	15,400
Case 3 ...	—	—	8,700	—	18,000

but the usual big variations between the granular and non-granular cells occurred when the patient resumed his ordinary life.

Effect of massage.—Three patients were given general massage, one for 20 minutes, the other two for 1 hour each. Very little difference was observed either in the total or differential counts taken before and after the massage.

TABLE V.

—	Length of Massage.	Total counts.		Polynuclear % counts	
		Before.	After.	Before.	After.
Case 1 ...	20 min.	6,800	7,200	60%	62%
Case 2 ...	1 hour.	10,000	10,600	51%	52%
Case 3 ...	1 hour.	13,000	13,700	56%	56%

Effect of exercise.—As the majority of patients showed symptoms of distress on exertion a test exercise was devised to see if these symptoms could be correlated to any change in the blood.

The test was carried out as follows. The patient was told to lie on his bed for one hour before coming to the laboratory, the ward and laboratory being on the same floor. Blood was taken for a differential count and a total leucocyte count. Then the patient was told to go down to the ground floor and back again 10 times at a sharp walk. This involved for each round the descent of two flights of stairs of 30 steps each, walking along the length of a corridor, the ascent of two corresponding flights of stairs, and along another corridor to the laboratory. The patients were watched and stopped if distress became evident. Some of the men were unable to carry out the complete test. A unit of exercise represents the ascent of one flight of 30 steps—i.e., a complete round was counted as 2 units of exercise. The amount of exercise in each case is given in the table, and the time taken over the exercise is noted. Blood was taken again for differential and total counts as soon as the exercise was finished, usually within two minutes of completing the test. The patient then had to lie on his bed for about an hour, and at the end of this period blood was taken again.

Muscular exercise is known to increase the number of leucocytes circulating in the peripheral blood, so it is important to note the degree of leucocytosis occurring in normal individuals as the result of the moderate exercise involved in the staircase test. The test was carried out on 7 controls in the same way as on the patients, except that Nos. 1 to 5 were sitting instead of lying down during the rest periods. Nos. 1 and 2 were medical men, Nos. 3, 4, and 5 were women, Nos. 6 and 7 patients admitted to the hospital for "irritable heart," but who did not show the typical symptoms on examination. No. 7 had recently suffered from an attack of malaria.

Table VI. gives the results of 14 observations in 13 patients, and Table VII. the results of 7 observations in 7 controls. The first test exercise was carried out by Captain Lyn Di mond, R.A.M.C., and the results of his observations are given under No. 5 in Table VI. Line A refers to the count taken after rest and immediately before exercise, Line B to the count immediately after exercise, and Line C to the count taken after the second period of rest. Chart II. gives the results of the total leucocyte counts in a graphic form.

** Not counted.

CHART II.

Total leucocyte counts. In each chain of three, the dots indicate: (1) Before exercise: (2) after exercise; (3) after rest 1 to 1½ hours.

It will be noted that the first two patients do not show a big rise in leucocytes after exercise, though the levels of the counts are high, but they do show a fairly large fall after rest. These two men did not have the preliminary hours' rest, but were walking about the wards. Therefore the

numbers given in Line C probably represent their leucocyte counts at rest more accurately than the numbers in Line A. It was after these two estimations had been made that the preliminary hour's rest was adopted in the test.

The average total count before exercise is 11,535, the average after exercise is 15,400. The average rise is therefore 33·6 per cent. If the first two men are omitted for the reason given above, the average rise is 40·4 per cent. The maximum individual rise is 84 per cent.

The average count in the controls before exercise was 7100 per c.mm., after exercise 8200, an average rise of 15·4 per cent.

Estimations of the leucocyte rise in normals after muscular exercise by other observers all refer to much more strenuous exercise than the staircase test. For instance, P. B. Hawk[3] estimated the total leucocyte counts before and after athletic competitions and training races. The exercise varied from a 100-yards sprint to a two-mile run. He found an average increase of 57 per cent., the maximum individual increase being 104·4 per cent. after three minutes' water polo. Hawk quotes the work of Willebrand,[4] who employed 12 athletic young men for his test. He gave them gymnastic exercises for 10 minutes, and did blood counts before exercise, immediately after, and again 1 to 1½ hours after. He found an increase in the leucocytes varying from 19·2 to 96·9 per cent., the average being 47 per cent. Neither of these observers appears to have done differential counts. Larrabee[5] also estimated the rise in leucocytes in four cases after a road race of 25 miles. The leucocytosis varied from 14,400 to 22,200 per c.mm.

Effect of exercise on the differential count.—The most constant change observed in the differential count was a rise in the lymphocytes immediately after exercise, and a fall of the same after a rest.

Ten cases showed a rise in the percentage of lymphocytes after exercise, one case showed a fall of lymphocytes of 7 per cent., three cases showed no change (1 per cent. or less). Of these three cases, two showed a fall of lymphocytes after rest; the remaining case was not counted for the third time. Only one case, therefore, differed from the general type—i.e., a rise of lymphocytes after exercise, a fall after rest. Some of the differences were small enough to come within the margin of error. Assuming that a rise or fall of more than 8 per cent. is outside the limits of error and therefore represents a real change in the composition of the blood, we find that five cases show changes within 8 per cent., eight cases show changes of the usual type of over 8 per cent. (maximum change 23·75 per cent.), one case shows a change of the opposite type (i.e., 7 per cent. fall of lymphocytes after exercise and a rise of 8·75 per cent. after rest). In four of the cases the percentage lymphocyte count rose above the polynuclear percentage after the exercise, the lymphocyte counts being 51, 52·25, 48·5, and 57·5 per cent.

Absolute Numbers of Leucocytes Before and After Exercise.

In the controls five showed a rise of lymphocytes after the exercise, two showed no change. In none of the controls was the variation greater than 7 per cent. Assuming, as before, that a rise or fall of less than 8 per cent. comes within the margin of error, it is difficult to say that there is any definite change in the proportions of the different cells after exercise.

Observations carried out by Captain Lyn Dimond showed approximately the same results. He made 11 observations on six patients before and after a staircase exercise. The total counts were not estimated. The differential counts showed that in nine observations there was a rise in the percentage of lymphocytes after exercise, in one observation there was no change, in the remaining case there was a fall of 11·5 per cent. in the lymphocytes. Of the nine observations showing a rise in lymphocytes, five gave a rise of 8 per cent. or over (maximum 14·5 per cent.), four gave a rise of less than 8 per cent. (2·5 to 5·5 per cent.).

As it has been demonstrated that all the cases show a rise in total leucocytes after exercise, and at the same time a majority show a percentage rise in lymphocytes, it follows that the increase in the number of white cells is largely composed of lymphocytes. Tables VIII. and IX. give the absolute numbers of the different cells in patients and controls in the exercise test. Basophils are omitted as the numbers are too small to be of any value. Taking the average of all the cases, the rise in polynuclears after exercise is 24 per cent., but the rise in lymphocytes is 48 per cent. Eosinophils and large mononuclears are both slightly increased in number after exercise, so that the leucocytosis is a mixed one, but the lymphocytes form the chief part of the increase. In the controls the rise in polynuclears after exercise is 13 per cent., the rise in lymphocytes 25 per cent.

In the next section the changes in the lymphocyte percentages will be noted more particularly, as the variations chiefly occur in them.

Clinical Symptoms of the Patients Tested by the Staircase Exercise.

No. 1, Ch.—Aged 26. History of chorea at 9 years of age. This patient had seen service in France. The onset of his symptoms had been gradual, dating back four years. He showed the usual symptoms of "irritable heart." He made no progress under treatment, and was discharged as permanently unfit. This patient did not have a rest before the exercise began, and therefore showed a high initial leucocyte count—viz., 17,600 per c.mm. The high level of all the leucocyte counts and the change in the percentage of lymphocytes (12 per cent.) would mark this case as a severe one, judging solely from the condition of the blood.

No. 2, Br.—Aged 22. No history of previous infection, service in France. Onset of symptoms had been gradual after service in the trenches. At the time of examination the patient showed the full symptoms of D.A.H. He made no progress, and was discharged as permanently unfit. This man also did not have the preliminary rest, and his initial count was 17,600 per c.mm., with a rise to 20,200 per c.mm. after exercise, and a rest count of 10,360 per c.mm. He showed a slight fall in lymphocytes, 7 per cent. after exercise instead of the usual rise, but the change is sufficiently small to come within the margin of error. Judging from the total leucocyte count the case is a severe one.

No. 3, He.—Aged 19. History of rheumatic fever in 1911. No service abroad. Onset of symptoms gradual since childhood, worse since rheumatic fever. The full symptoms of D.A.H. were present. He made no progress, and was discharged as permanently unfit. The two leucocyte counts taken after rest were practically identical—viz., 14,500 and 13,600. The count after exercise was 20,600. The lymphocytes showed a typical rise of 10 per cent. after exercise and a fall of 20 per cent. after rest. These two points, the 42 per cent. rise of total leucocytes and the 20 per cent. change in lymphocytes, mark the case as a severe one.

No. 4, G.—Aged 24. History of frequent sore-throats. No service abroad. Onset of symptoms gradual, dating back several years. He showed the full symptoms of D.A.H., made no progress, and was discharged as permanently unfit. From the hæmatological point of view this case was the most severe of the series. The total leucocyte count showed a rise of 84 per cent. after 14 units of exercise up to 23,800 per c.mm., and the lymphocytes showed a small rise after exercise, but a fall of 21·75 per cent. after rest.

No. 5, T.—Aged 18½. History of scarlet fever and diphtheria in childhood. Service in France. Onset of symptoms gradual during many years. Full symptoms of D.A.H. were present and the heart was enlarged. He made no progress and was discharged as permanently unfit. This patient showed a rise of 65 per cent. in the total count up to 15,000 per c.mm. His differential count showed little variation, the lymphocytes showing a fall of 2·75 after rest and the polynuclears a rise of 5 per cent. Although the differential count does not give any definite indication, the big rise in the total leucocytes marks the case as severe.

No. 6, Be.—Aged 21. History of scarlet fever and rheumatism in 1907. No service abroad. Onset gradual since illness in 1907. The full symptoms of D.A.H. were present. The patient made no progress and was discharged as permanently unfit. This patient had a total count of 16,700 per c.mm. after exercise and a count of 9600 after the second rest. The percentage of lymphocytes showed no change after the exercise, but a fall of 16·25 per cent. after a rest. Therefore the case was regarded as a severe one.

No. 7, Q.—Aged 24. History of tonsillitis in 1914. No service abroad. Had had symptoms for many years. He did not show any improvement and was discharged as fit for sedentary work. Although this patient did not show any improvement, his case was considered to be, clinically, one of the least severe of the series, and there was a suspicion that he was making the most of his symptoms. This case from the

hæmatological point of view did not show any characteristic points, except that the lymphocyte count was somewhat high, 44·5 per cent. All the total counts fell within normal limits, only a rise from 6900 to 8700 per c.mm. after exercise being noted. The differential counts before and after exercise were practically identical. This patient only did a short exercise, four times the two flights of stairs, as he said he could not go on, though he showed no objective signs of distress. It was noted at the time that he made no attempt to exert himself.

Two views may be taken of this patient. First, that he was a genuine slight case of D.A.H., but did not exert himself sufficiently to show the characteristic changes, against which view is the normal total count after slight exercise, and in favour of it the relatively high lymphocyte counts. Second, that this case was not a genuine one of D.A.H., and that the blood counts confirmed the clinical suspicion of malingering.

No. 8, Wa.—Aged 19. History of chronic suppuration and otitis media. Service in France. Onset of symptoms sudden, following bombardment. His symptoms of D.A.H. were mild, he made slight progress, and was discharged in category "a" (fit for general service). This case showed a small rise in total leucocytes after exercise, from 11,100 to 13,700 per c.mm. There was little change in the differential count the lymphocytes rose 4 per cent. after exercise and fell 2 per cent. after. There was no lymphocytosis, the highest reading being 32·25 per cent. Here the blood picture appears to confirm the clinical diagnosis of a mild case.

No. 9, Cu.—Aged 21. No history of previous infection. Service in France and the Dardanelles. Symptoms came on after four months' service in France and after "malaria" and dysentery. He showed the usual symptoms, but improved under treatment. This patient did not show very marked changes in the blood. The leucocyte count at rest was 10,900 and after exercise 12,100. The lymphocytes rose 11 per cent. after exercise and fell 7·5 per cent. after rest. The highest lymphocyte reading was 39·25 per cent. From the blood findings the case should be classed as a mild one.

No. 10, Cl.—Aged 24. History of "brain fever" as a baby. Service in France. Onset of symptoms gradual after one year in France. He showed the usual symptoms, which improved slightly, but he was only able to proceed to the higher exercises with difficulty. This patient only showed a moderate rise in leucocytes after exercise —viz., 9000 to 11,620. His lymphocytes rose 5·5 per cent. after exercise and fell 5·25 per cent. after rest. He was therefore classed at a mild case. The first test was carried out in the third week after admission. In the seventh week the test was repeated, except that the third estimation was not carried out. Very little change was observed. The leucocytes rose from 9,700 to 11,700 per c.mm., and the lymphocytes rose 3·25 per cent. The highest lymphocyte reading was 37 per cent. on the first date, and 33.25 per cent. on the second. From the blood findings the patient had made no improvement, though the variations are not very marked.

No. 11. Ha.—Aged 19. History of whooping cough, chicken-pox, tonsillitis. No service in France. Symptoms for several years. He showed the full symptoms of D.A.H., made no progress, and was discharged as permanently unfit. This case is interesting, as the leucocyte count at rest was normal, 7,000, rose to 9,500 per c.mm. after exercise (he only did eight units of exercise), but his lymphocytes showed a big rise from 36·25 to 52·25 per cent., and fell again after exercise to 34·5. The absolute numbers show that the increase in leucocytes was almost entirely due to lymphocytes, the polynuclear numbers remaining practically stationary, so that the readings after exercise were 40·5 polynuclears and 4963 lymphocytes. From this case it would appear to be necessary to do a differential count as well as a total count in the test exercise, otherwise the lymphocytosis and big variation in percentages would not be noticed.

Nos. 12 and 13 Wi.—The two estimations refer to the same patient. The first was made in the fourth week after admission, the second in the tenth week. Aged 24. No history of previous infections. Service in France. Onset of symptoms gradual after one year in France. His symptoms were moderate. He made considerable progress while in hospital, and was discharged in category "a." On the first occasion patient could only do 8 units of exercise. The rest count was 10,000, after exercise 18,200. The lymphocytes rose 12·5 per cent. and fell 9·25 per cent. after rest. These findings would mark the case as severe. Six weeks later the test was repeated; this time the patient did 16 units of exercise. The total count rose from 9000 to 12,400 and the lymphocytes rose 5·5 per cent. On these findings alone the case would be classed as mild. Two weeks later, just before the patient's discharge, when he was sufficiently fit to do route marches, an estimation was done without any preliminary rest or exercise. The total count was 7300 per c.mm. and the polynuclear percentage 59. This case seems to indicate that the condition of the blood varies with the general progress, and that one test exercise is not of much value in the prognosis, although it may be useful for diagnosis.

No. 14, A.—Aged 22. Symptoms for several years. No history of previous infection. Service in Mesopotamia. Present symptoms of moderate severity; no progress. This patient had a high lymphocyte count throughout. He was found to be a carrier of *Entamœba histolytica*. He showed the characteristic change in the blood after exercise.

A list of these patients drawn up by the clinicians in accordance with the severity of the symptoms was compared with a similar list based on the blood findings. The correspondence between the two methods of classification was very close.

The four most severe cases by clinical standards showed the highest total leucocyte counts after exercise (18,000 to 23,800), the four least severe cases showed only a moderate leucocytosis after exercise (8700 to 13,700). The remaining cases were intermediate to the above groups both in the severity of their symptoms and in the degree of leucocytosis (9500 to 18,000). A big rise in the lymphocyte percentage after exercise was regarded as a sign of some severity, even if the total count was below 10,000 per c.mm.

An analysis of these cases demonstrates that the men who have a history of symptoms dating back many years show a higher lymphocyte count than the men who date their symptoms as subsequent to service abroad.

The cases may be divided into two classes: In Class A, in which the onset of symptoms dates back to civilian life, the highest lymphocyte counts are respectively, Case 1, 48·5 per cent.; Case 3, 44 per cent.; Case 4, 51 per cent.; Case 5, 37 per cent.; Case 6, 45·5 per cent.; Case 7, 44·75 per cent.; Case 11, 52·25 per cent.; Case 14, 57·5 per cent. The average is 47·5 per cent. In Class B, in which the onset of symptoms is dated from the strain of actual service in the trenches, the highest lymphocyte counts are respectively, Case 2, 41·5 per cent.; Case 8, 32·25 per cent.; Case 9, 39·25 per cent.; Case 10, 37 per cent.; Case 12, 41 per cent. The average is 38·2 per cent. In the controls the average of the highest lymphocyte counts is 38·2 per cent. Of the first class, A, three of the eight men had served abroad, six were discharged as permanently unfit, one case, No. 7, in which there was a suspicion of malingering, was discharged in category "d," and one is still in hospital. In the second class, B, all had served abroad, three of the five men were discharged in category "a," one as permanently unfit; the other one is still in hospital.

This classification seems to indicate that men who have shown signs of "unfitness" in civilian life are very liable to break down while still in training, and are not likely to improve much under treatment, while the men who have passed through their training successfully and then break down under the strain of foreign service are likely to obtain considerable benefit from treatment.

Diagnosis.—Patients with conspicuous symptoms of "irritable heart" show in nearly every case a moderate leucocytosis. Patients with slight symptoms may only show the leucocytosis after moderate exercise. The same amount of exercise in normal individuals will produce a smaller response. Patients with symptoms of long standing are more apt to show a higher lymphocyte count than those with symptoms of recent origin. This, however, is not invariable, as the patient who showed the most marked degree of lymphocytosis had a history of only six weeks' duration. The percentage rise in lymphocytes may be considerable in patients who do not show any appreciable rise in the number of leucocytes after exercise. It is therefore necessary to estimate both the total and differential counts if the effect of exercise is to be used as a point in diagnosis. As a help in diagnosis it is suggested that the following test should be carried out.

The patient should be made to perform an amount of muscular work equivalent to the staircase exercise, and his total and differential counts estimated immediately afterwards. He should then lie down for an hour while the counts are in process of estimation. If the total count is below 11,000, and the lymphocyte count is below 45 per cent., he can be regarded as negative, and a second count is unnecessary. If, however, the total count is below 11,000, but the lymphocyte count above 45 per cent., a second estimation should be made after an hour's rest. If the total count immediately after exercise falls between 11,000 and 14,000 per c.mm., the condition may be regarded as mild, when the count falls above 14,000 as moderately severe. If after exercise the total count is below 11,000, but the lymphocyte count is high (above 45 per cent.), and after rest shows a big percentage fall (10 to 20 per cent.) the case may be regarded as moderately severe.

A few illustrations will show how the test can be shortened in practice. Nos. 1, 2, and 3 were three consecutive patients sent up to the hospital for diagnosis. No. 1 did 20 units of exercise; his total count immediately after was 8600 per c.mm. and his percentage of polynuclears 62. The findings were negative and no further examination was done. No. 2 did 12 units of exercise; his total count immediately after was 16,700 per c.mm.; this alone was sufficient to class him as a moderately severe case. No. 3 did 20 units of exercise; his total count after was 12,000 per c.mm., polynuclear percentage 77. He was regarded as a mild case. In each instance the clinical findings agreed with the findings based on the leucocyte estimations.

It cannot be said definitely that a normal blood count in these patients excludes a diagnosis of "irritable heart." On the other hand, a blood count which shows a marked deviation from the normal is a positive sign entirely outside the control of the patient, and may be regarded as a definite objective point in diagnosis. The blood count does not give much help in prognosis, as the condition of the blood appears to vary with the general condition, and this can be judged by the usual clinical methods.

The degree of lymphocytosis present in many of these cases appears to bear out the statement of Curschmann[6] that a high lymphocyte count is indicative of a "substandard" constitution. This author only gives percentages from the differential count, and does not make any statement as to the total number of leucocytes present in his cases.

Summary.—The following conclusions apply to patients who show the signs and symptoms referred to at present under the term "irritable heart."

1. At absolute rest there is a slight leucocytosis or no leucocytosis.

2. While up and about there is a decided leucocytosis. In many, and especially in cases of long standing, there may be a relative and absolute lymphocytosis.

3. The variability of the different kinds of leucocytes is greater (more than double) than in normal individuals.

4. The response to muscular exercise is similar to that found in healthy subjects, but is exaggerated in its degree. This exaggerated response can be used as an objective sign in diagnosis.

5. The degree of leucocytosis and of variability in percentages after exercise is proportionate to the severity of the symptoms.

Addendum.

The error of differential counts.—The question of making a reasonably accurate differential count presented some difficulty. Owing to the fact that many of the preparations had to be made at different times of the day and by different individuals, it was necessary to depend upon a dried film as a routine. Also the object in view was to devise a method which could be carried out as a clinical test. Thus in the test exercise described above three estimations of total leucocytes and three differential counts had to be carried out, so that the smallest number of cells compatible with reasonable accuracy were counted. Four hundred cells were counted as a routine, and an attempt was made to estimate the margin of error by the method used. The films were spread by one slide upon another. This method undoubtedly exercises a selective action, some of the larger leucocytes being carried along to the edge of the film. A large error is possible by simply counting down the middle of the films. The routine adopted was to count 400 cells—100 down the middle, another 100 right across the slide, another along one of the sides, and another at the end of the film. This method of distributing the count appeared to be satisfactory, as the same slides counted by two observers gave approximately the same results.

Comparison of wet and dry counts.—The error was estimated by counting a dry film against a wet preparation. Dry and wet films were prepared simultaneously, and 400 cells were counted in each by two observers independently, and the results compared, the count in the dry film being distributed as described above. The wet film was prepared in the following manner, the procedure being a combination of the wet counting methods recommended by A. G. Phear[7] and Hill.[8] The stain was prepared according to Hill's method, except that Jenner's stain was found to be as good as, if not better than, Wright's for the purpose. One soloid stain (Wright or Jenner) was dissolved in 10 c.c. of pure methyl alcohol. The actual diluent was made up fresh each day from this stock solution in the following proportions: Distilled water, 12 parts; acetone, 3 parts, methyl alcohol, 1 part; stain (filtered), 4 parts. The mixture must be thoroughly shaken.

A small drop of blood is picked up on a slide, a small quantity of the diluent dropped on it, and the blood is mixed with the stain by blowing a current of air on to the surface of the drop through a pipette. This mixing must be done quickly, otherwise the acetone will evaporate and the eosin-methylene blue combination will be precipitated. The least trace of acidity will cause precipitation. The drop is covered quickly by a cover-slip, the under surface of which has been previously rimmed with liquid parolein for one-eighth of an inch. The leucocytes can be easily recognised and counted with a 1/8 in. objective. The details are seen best with a 1/12 in. objective, the light being considerably reduced. The eosinophils stand out brilliantly, the granules stain a deep crimson and are so prominent that the nucleus is almost obscured. In the polynuclears the protoplasm takes up a pinkish colour and the granules are very noticeable. The shape of the nucleus is not so clearly defined as in a dry film. The large mononuclears are distinctive, appearing as large oval cells with a relatively small kidney-shaped nucleus, the protoplasm having a distinct bluish tinge. In the lymphocytes the protoplasm is practically colourless.

Six consecutive parallel counts carried out by two observers independently gave the following results, 400 cells being counted in each. Nos. 1 and 2 from a control. Nos. 3 to 6 from 2 patients. (Table X.)

TABLE X.—*Comparison of Wet and Dry Films.*

	Wet Counts. (Counted by Observer A.)					*Dry Counts.* (Counted by Observer B.)				
	Differential count, 400 cells.					Differential count, 400 cells.				
No.	Poly-nuclears.	Lympho-cytes.	Eosino-phils.	Large mono-nuclears.	Baso-phils.	Poly-nuclears.	Lympho-cytes.	Eosino-phils.	Large mono-nuclears.	Baso-phils.
1	64·5	32·25	1·0	2·25	0	65·0	30·5	2·5	1·0	1·0
2	64·0	32·75	2·0	1·25	0	63·0	32·0	2·25	2·0	0·75
3	58·0	34·0	5·0	2·5	0·5	61·75	33·25	3·0	1·75	0·25
4	55·0	37·0	4·5	3·0	0·5	56·25	38·75	3·25	1·25	0·5
5	62·0	31·0	3·25	3·0	0·75	62·25	33·0	2·0	2·25	0·5
6	45·0	45·5	5·25	3·5	0·75	48·0	44·0	4·0	3·0	1·5

Taking the wet counts as a standard, the dry counts show an average error of 1·5 per cent., with a maximum error of 3·75 per cent. That the cells are evenly distributed in the wet films can be proved by comparing the numbers of polynuclears in the different hundreds. Thus, in one wet film, 400 cells were first counted at random. The percentage of polynuclears was 64·5. Then an attempt was made to count every cell in the film (over 3200). The percentage was 64·37, and the eight successive lots of 400 each gave percentages of 60·5, 67, 64, 63·25, 60·75, 68·25, 65, and 66·25. The chances of error may be gauged from the following statement taken from statistical tables[9]: given a count of 403 leucocytes, and an observed percentage of 39 lymphocytes, the chances are 9 to 1 that the error will fall within 4 per cent.—i.e., that the truth will lie between 35 per cent. and 43 per cent. Throughout the paper the probable margin of error has been considered to be 4 per cent. in a differential count of 400 cells.

In conclusion, I wish to acknowledge my indebtedness to Captain Lyn Dimond, R.A.M C., for his help in carrying out the investigation, and also to Miss I. B. Matthews, of Toronto, for the great assistance she has given in making many of the differential counts.

THE INFLUENCE OF MATERNAL ORAL SEPSIS ON THE FŒTUS AND MARASMIC CHILDREN.

BY E. SPENCER PIERREPONT, L.D.S. R.C.S. ENG.,

DENTAL SURGEON TO THE EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL, E.; AND TO THE PRINCE OF WALES'S GENERAL HOSPITAL, TOTTENHAM, N.

AT a time like the present, when the children of the British Empire are such an imperial necessity and asset to the nation, it is the aim of every medical man to do all in his power to enable those children to be as healthy and vigorous as possible; therefore it appears opportune to call attention to a condition of maternal oral sepsis and its resulting evils upon the children that has not received any attention from the medical world before the present investigations were undertaken, so far as I am aware. For the past nine years observation has been kept by myself upon marasmic children and their mothers, and also those children who, being breast-fed, yet suffered from vomiting and diarrhœa, and the conditions of the mothers' mouths carefully noted. The clinical evidence strongly points to the septic condition of the mother's mouth having a very marked effect upon both the fœtus and the post-natal condition of the child. The cases examined do not include such obvious causes as syphilis and other well-known conditions, that are universally admitted to cause stunting in growth or wasting in children, &c., but are all cases where clinically nothing of a pathological condition was found in the mother other than in the mouth. In some cases, however, the mother's milk rapidly failed; later in this article this matter will be discussed.

All the cases examined, and of which notes were made, were first examined by physicians as to their condition, and then

referred to the author as being more or less obscure, and about whom nothing definite was known. In an article by Dr. J. W. Ballantyne [1] he says:—

"It has been shown that in the lower animals the placenta has a real affinity for some toxic bodies, and by storing them up in its substance prevents them passing to the fœtus. In this respect it resembles the action of the liver in the adult, being an accumulator of poisons. Of course, it does not necessarily prevent their passage, although it may store them up. Bacteriological researches have shown that through it can pass the bacillus of anthrax, of fowl cholera, typhoid fever, the pneumococcus, the streptococcus, the spirillum of Obermeier, the bacillus of glanders, the pathogenic organism of hydrophobia, and, perhaps, the hæmatozoon of malaria. So we have now to look at the opposite side of the question, viz., the placenta as a means of access of germs and toxins to the fœtus. It would seem also that it is not necessary for the placenta to be macroscopically diseased, as by hæmorrhage into its substance, in order that the organisms may pass; in fact, in some cases in which the germs have passed the placental tissue does not appear to have been even microscopically affected. The fact that it is through the placenta that infection reaches the fœtus has an important bearing upon the primary lesions in the fœtus. The germs and toxins arrive at the body in the blood, passing first through the placenta and umbilical vein, then either through the liver or ductus venosus, then through the heart, and so to the whole circulation. Erysipelas in the mother has been found associated with streptococcic endocarditis in the fœtus and not with erysipelatous inflammation of the fœtal skin (reported by Bidone). Atrophic conditions of the subcutaneous tissue are sometimes found as congenital states."

Now, if these conditions have been demonstrated and certain well-defined micro-organisms found in the fœtus, logically the toxins from the maternal septic mouth should also produce their effect on the fœtus by the same means of transmission. On the other hand, the mother may herself acquire a certain amount of immunity by antibodies from her own toxins, and that would explain the birth of certain healthy and vigorous children in spite of the maternal oral sepsis.

Stress is laid upon the term oral sepsis, as certain of the mothers' mouths showed the teeth to be well formed, free from caries, and with all the teeth *in situ*. In many cases where the mother had several children there was found a progressively increasing change for the worse in the health and vigour of the younger children of a greater degree of intensity than one would expect to find as the result of repeated pregnancies, suggesting other agencies at work than the natural exhaustion of the mother, and explicable on the ground of a successively increasing toxæmia. The following cases will give some data for arriving at certain definite conclusions, but it must be understood that these cases are just ordinary ones occurring in hospital practice, as all the material for this article has been obtained from patients attending the East London Hospital for Children, Shadwell, and the Prince of Wales's General Hospital, Tottenham, and not from private practice.

CASE 1.—Male, aged 8 weeks. Marasmus. Weight 10 lb. 4 oz. Breast-fed. Vomits after each feed. Motions curdy. Very flatulent. Condition of mother's mouth: Very septic; teeth [2] $\frac{8^{***}\ 7^{***}\ 4}{8\ \ 7\ 6\ 5\ 3}\ |\ \frac{5^{*}\ 7^{*}\ 8^{***}}{3\ 4\ 5\ 7\ 8}$ all badly carious and septic. Had six children, two living, including the patient, and four dead. Eldest and youngest alive. Mother fed children on breast for first few weeks; then on bottle, as her milk went.

CASE 2.—Male, aged 2½ months. Marasmus. Weight 6 lb. 2 oz. Breast-fed for first two weeks; Nestlé's milk after. Condition of mother's mouth: Very septic; salivary calculus; pus and chronic gingivitis round all teeth. $\frac{6^{***}\ |\ 6}{6\ \ \ 5\ |\ 6}$ carious. Mother had eight children, three living, five dead. The patient was the first marasmic child, according to the mother's statement. Mother's milk went soon after she got up with all the earlier children; last three children breast-fed. The two born immediately before the patient had died. Mother aged 34; father 33, healthy.

CASE 3.—Male, aged 10 weeks. Marasmus; weight 5 lb. 14 oz. Bottle-fed from birth. Condition of mother's mouth: Oral sepsis; teeth good except $\frac{|\ 2}{6\ |}$ carious. Chronic gingivitis. Salivary calculus and pus round necks of teeth. Had five children. Child immediately before this one, dead: others alive and healthy. Dead child marasmic; breast-fed. Mother aged 27; father 28, healthy.

CASE 4.—Male, aged 5 months. Marasmus. Breast-fed. Condition of mother's mouth: Oral sepsis; chronic interstitial gingivitis and débris of food at necks of teeth; septic roots of $\frac{|}{6^{**}\ 5^{*}\ |}$; teeth good and well formed. Mother was advised to have her mouth treated but refused, so advised that child should be taken off breast and artificially fed. Mother had nine children, four dead, five living. Child older than the patient, aged 2 years, wasted until 14 months old, when it was taken off the breast. Second and third children breast-fed for five months and died of marasmus.

CASE 5.—Female, aged 5 months. Marasmus; weight 8 lb. 5 oz. Breast-fed. First child. Always sick after breast, almost immediately. Condition of mother's mouth: Oral sepsis; salivary calculus and pyorrhœa alveolaris round lower incisors; some chronic gingivitis round upper teeth. Teeth good. No caries; $\frac{|}{6\ 5\ |}$ have been extracted. Mother aged 20; father 22, healthy.

CASE 6.—Male aged 4 months. Marasmus; weight 6 lb. Breast-fed for three months, then milk and barley-water. Had diarrhœa last four weeks. No vomiting. Child died in hospital. Post-mortem report: "All viscera normal as far as could be ascertained." Condition of mother's mouth: Very foul and septic. Would not allow a proper examination to be made. Much pus could be squeezed out round lower incisors by finger.

CASE 7.—Male, aged 12 months. Marasmus; weight 11 lb. 8 oz. Breast-fed. Condition of mother's mouth. Very septic, pyorrhœa alveolaris at incisor region. Teeth: $\frac{7^{***}\ |\ 6^{***}\ 7^{***}}{|}$, all suppurating. Had six children altogether, four living (aged 10, 9, and 5 years, and the patient). The two children born immediately before the patient had died from marasmus. Mother, aged 36.

CASE 8.—Male, aged 6 weeks. Marasmus; weight 8 lb. Breast-fed. Condition of mother's mouth. Terribly septic, all teeth bathed in pus. Teeth in mouth:—

$$\frac{8\ 7\ 6^{***}\ 5\ 4\ 3\ 2\ 1\ |\ 1\ 2\ 3\ 4\ 5^{*}\ 6\ 7}{8\ \ \ \ \ \ \ 5\ 4\ 3\ 2\ 1\ |\ 1\ 2\ 3\ 4\ 5\ \ \ \ \ 8^{*}}$$

Had five children altogether; eldest healthy, fourth child sickly, and fifth the present one. Second and third children died at the age of 9 months of marasmus. Mother's age 37.

CASE 9.—Male aged 2 months. Marasmus; weight 9 lb. Twin brother of patient in hospital for "wasting." Both breast-fed. Condition of mother's mouth: Very septic; full of septic roots. All the teeth decayed and on level of gum as roots, and mostly suppurating. Never had any extracted. Had five children altogether, eldest healthy; second not so strong, third sickly. Mother aged 32.

CASE 10.—Female aged 3 months. Marasmus; weight, 5 lb. 2 oz. Breast-fed. Vomits immediately after feed. Two weeks in hospital, then died. Condition of mother's mouth: Oral sepsis; teeth *very* good; severe chronic interstitial gingivitis; food débris (old) round necks of teeth and subgingival calculus; no pus. Oral sepsis for want of toothbrush. Has two children (living and healthy) besides the patient, both breast-fed. Mother aged 22 years and 10 months; father 31, healthy.

CASE 11.—Male aged 3 years and 9 months. When first brought up for treatment was marasmic. Breast-fed. Taken off breast and artificially fed. Now fine healthy boy. Mother's mouth very septic when first seen. Full of suppurating roots, which have all been removed and mouth treated.

CASE 12.—Female, aged 2 months. Marasmus; weight 6 lb. 6 oz. Breast-fed. Condition of mother's mouth: Full of septic roots and pyorrhœa alveolaris. The patient was the only child. Mother aged 26; father 31, healthy.

CASE 13.—Male, aged 3 months. Marasmus; weight 7 lb. 2 oz. Breast-fed. Condition of mother's mouth: Full of very septic roots and teeth. Two other children, aged 2 and 3 years; eldest healthy, second not so strong.

CASE 14.—Male, aged 4 months. Marasmus. Breast-fed. Condition of mother's mouth: Oral sepsis; $\frac{8^{***}\ 2^{*}\ |\ 2^{*}7^{***}8^{***}}{8^{**}5^{*}4^{*}\ |\ \ \ \ \ \ \ \ 8^{**}}$ carious and septic; some gingivitis. Four living and healthy children besides the patient. Father healthy.

CASE 15.—Female, aged 10 weeks. Marasmus; weight at birth 9 lb.; present weight 8 lb. 2 oz. Bottle-fed from birth. Condition of mother's mouth: Pyorrhœa alveolaris; carious and septic teeth $\frac{7\ 6\ 4\ |\ 6}{8\ 7^{**}\ |\ 7^{**}\ 8^{*}}$. Had 12 children altogether; five alive, all bottle-fed. Father healthy.

[1] "Pathology of Pregnancy," Green's Encyclopædia of Medicine.
[2] An * after a number signifies a root.

CASE 16.—Female, aged 1 year and 2 months. Marasmus. Breast-fed. Wasted up to the age of 8 months, then taken off breast and put on bottle. Condition of mother's mouth: Very septic; pyorrhœa alveolaris and salivary calculus. Teeth: $\frac{7^{***}\ 6^{***}\ 5^{*}\ 4^{*}\ 2^{*}}{6}$ | $\frac{2^{*}\ 4^{*}\ 6^{***}\ 7^{***}}{3^{*}4^{*}\qquad 8^{**}}$ carious and septic. Three more children alive, all healthy. Eldest bottle-fed, others on breast.

CASE 17.—Female, aged 6 weeks. Marasmus; weight 3½ lb. Premature child, between seven and eight months. Condition of mother's mouth: Exceptionally foul and septic. Sleeps with upper denture (vulcanite, covering palate) in mouth. Has not removed denture from mouth for 12 months. Said she was told by dentist (?) never to take it out of mouth. On removal, palatine surface of denture covered with decomposed food, &c.; very malodorous. Palate very inflamed and covered with ulcerating patches; four carious teeth in mouth. Six children living and healthy; one (next to patient) dead (marasmus); all breast-fed.

CASE 18.—Male, aged 7 weeks. Marasmus; weight at birth, 10 lb.; present weight, 6 lb. Breast-fed. Condition of mother's mouth: Oral sepsis; pyorrhœa alveolaris round lower incisors. Teeth: $\frac{6^{*}\ 4^{*}\ 1^{*}}{4^{*}}$ | $\frac{1^{*}\ 2^{*}\ 3^{*}\ 4^{*}\ 5^{*}}{\qquad}$ all carious and septic. Had four children and one miscarriage. Miscarriage before birth of patient, 18 months ago. Also boy of seven months died half an hour after birth. All children breast-fed; two eldest children healthy. Mother aged 33; father 37, healthy.

CASE 19.—Female, aged 13 months. Marasmus. Breast-fed until the age of 3 months; bottle-fed since. Condition of mother's mouth: Oral sepsis; chronic gingivitis; pus round necks of teeth. Teeth: $\frac{6\ 4^{*}}{7^{**}6^{**}}$ | $\frac{6^{**}}{8^{**}}$ carious and septic. Had three children and one miscarriage at six months before the birth of the patient. Mother's milk gradually goes when she gets up, and not then sufficient to feed children. Mother aged 29; father 29, healthy.

CASE 20.—Male, aged 3½ months. Marasmus; weight, 9 lb. 5 oz. Breast-fed. Condition of mother's mouth: Great congestion of gums; salivary calculus round teeth. Teeth: $\frac{\qquad}{4^{*}\ 5^{*}\ 8^{***}}$ carious and septic. Milk gradually went six weeks after the birth of this child. Four children besides this one, all alive and healthy.

In the analysis of these cases it will be noticed that the health of the children becomes progressively worse in the younger ones in Cases 1, 2, 3, 4, 7, 8, 9, 13, 17, 18, and 19, pointing to an increasing maternal toxæmia as the condition of the mother's mouth becomes more septic, this sepsis having an adverse effect upon the health of the children. In Case 17 the mucous membrane of the mother's mouth covered by the denture was exceedingly inflamed and covered with small areas of ulceration, the whole forming, in fact, an ideal area for the absorption of toxic material. The mother expressed herself very strongly in terms of indignation when it was suggested to her that the condition of her mouth might be the cause of her child's health and the prematurity of its birth, as she considered it clean, and a stigma had been cast upon her. Certainly the sepsis arising from the retained denture had more to do with the child's condition than anything else. In Cases 1, 2, 3, 4, 7, 8, 15, 17, and 18 one or more children were dead. It is not claimed in every case that the maternal oral sepsis was the cause of the death of all these children; but it does seem to suggest that the children were born with a vitality impaired, caused by a maternal toxæmia, and therefore the children were less resistant to the common diseases of childhood than children whose vitality is unimpaired.

In Cases 18 and 19 miscarriage occurred immediately preceding the birth of the marasmic children, and in Cases 17 and 18 there were premature children. It is well known how often the above two conditions are produced by syphilis, and if a syphilitic toxæmia is capable of producing these conditions; it is surely not unreasonable to expect certain other toxæmias to have a similar effect upon the fœtus. There is not sufficient data collected yet to be dogmatic upon this point, but it would seem as if an oral sepsis in certain cases were the deciding factor.

In Cases 5 and 10 the child vomits after taking the breast, thereby showing there is some strong disturbance in the alimentary tract, and giving evidence of a toxic condition of the mother's milk. Dr. J. Haig Ferguson, in his article on "The Pathology of the Puerperium,"[3] writes as follows:

"Organisms can gain access to the breast through its numerous ducts when there are any abrasions on the nipple or areola, and as such breaches of surface are frequent in lactating women the entrance of pathogenic organisms readily takes place. These organisms are mostly pyogenic, and thus it is not to be wondered at that the least abrasion of the nipple becomes a septic wound. Healthy mother's milk does not come from the breast absolutely sterile. Staphylococcus pyogenes albus and aureus are commonly found and probably find their way into the milk from without, through the milk ducts. On the other hand, organisms may reach the milk through the blood in women suffering from septic diseases."

If organisms can reach the milk through the blood it is much more likely that toxins should reach it by the same channel.

In Cases 1, 2, 19, and 20 the mother's milk disappears. In many cases the disappearance of the mother's milk would point to the selective affinity of certain toxins on the secreting cells of the mammæ, thereby producing in some cases a diminution in the quantity of the milk, and in others a deficiency in the normal constituents (e.g., fats, salts, &c.) of the milk. In some 10,000 cases of infantile diarrhœa and vomiting where the children have been suckled on the breast, these cases extending over a period of nearly 10 years, the child has been immediately taken off the breast and artificially fed, and in the great majority of cases the diarrhœa or vomiting has ceased. These cases have been treated by different resident and also non-resident medical officers on my urgent representations, and in many cases the mother's mouth has been treated, and the child again fed on the breast with gratifying result. The same treatment has been carried out in numerous cases of wasting children with marked good results, proving beyond doubt that the toxic effect of the mother's milk was due to oral sepsis.

Dr. J. Lamond Lackie writes in his article on "The Physiology of Pregnancy"[4]:—

"Pregnancy creates important changes in the different systems and organs of the body. The blood and the nervous system are affected to the greatest extent, but practically all the functions of the body are more or less modified. Since the pregnant woman has to perform nutritive and excretory functions for herself and her fœtus extensive changes in the general system must occur. So long as these changes take place within certain limits, health is preserved and improved, but when carried to excess they lead to serious complications. Much has been written on the subject of the toxæmia of pregnancy. It is now believed by some authorities that many of the hitherto supposed physiological symptoms of pregnancy are the results of slight toxæmia, and that the graver complications of pregnancy, labour, and the puerperium are due to intense toxic infection. Vomiting, pigmentary changes in the skin, neuralgia, irritability of temper, &c., have generally been supposed to be normal, since they are so common, but possibly they are due to the presence of toxins. As pregnancy advances the general economy becomes adapted to the new conditions and the symptoms of poisoning pass off. The emunctory organs work at high pressure, but if one of them gives way, then symptoms of toxæmia become intensified, and may become so serious as to endanger the patient's life. Eclampsia is the most striking example of severe toxic infection. It is no longer regarded as a disease primarily of the kidneys. The causes of these toxic conditions during pregnancy, labour, and the puerperium are varied, and include heredity, climate, previous renal disease, dyspepsia, hepatic disorders, anæmia, and tight lacing. Early recognition of toxic symptoms is important, as active treatment is frequently necessary to prevent serious complications."

Now, looking at these conditions of toxæmia, two of which at least are known to be influenced by oral sepsis—viz., dyspepsia and anæmia—it does seem rational that any toxic state in the mother, other than metabolic, might be the factor that would induce one or other of these toxæmias of pregnancy and act as the proverbial straw that breaks the camel's back, and when no other toxic focus can be ascertained, and a septic condition of the mouth is present, it is logical to assume that that sepsis may make all the difference between a normal and a pathological pregnancy.

The conclusions drawn from a series of some 500 cases, from which the above 20 cases are a fair selection, are:—

1. The toxins from the maternal oral sepsis have a very strong influence in a large number of cases upon the vitality of the rapidly growing fœtus, so that the child is handicapped from before birth with a lowered vitality, and therefore the marasmic condition is ante-natal in its inception.

[3] Green's Encyclopædia of Medicine.

[4] Ibid.

2. That prematurity of birth and miscarriages, where no other cause can be discovered, are brought about by the toxic state of the mother induced by the septic condition of her mouth.

3. The diminution in the quantity, or alteration in the quality, of the mother's milk, where no other cause can be ascertained, is due to the selective affinity of certain toxins for certain secretory cells of the mammæ, and where no such diminution or alteration can be demonstrated, then the toxins, and in some cases micro-organisms themselves, are in the milk.

4. In the toxæmias of pregnancy and the puerperium the high pressure at which the emunctory organs are working is probably adversely influenced by the toxic state produced by the mouth, and this is the deciding factor in many cases that just brings the balance down on the wrong side and results in eclampsia or the other toxæmic conditions.

I would like to take this opportunity of thanking all those who have been good enough to help me in my investigations, especially Dr. R. S. Frew, for referring numerous cases, and also Dr. Gordon Moore and Dr. Eisdell Moore for their interest in the subject, and also for their care in the treatment of cases. Sister Berkeley, for the trouble she displayed in getting the mothers of in-patients to come to see me, is especially thanked. Dr. Harold K. Waller, whilst resident medical officer at the East London Hospital for Children, also referred some cases to me for investigation.

If the interest of the medical world can be aroused to take some notice of the important rôle which oral sepsis plays in pregnant women, this article will not have been written in vain; and a plea is here made for the systematic examination and treatment of the mouths of expectant mothers, as marasmus in children should be treated whilst the child is still in utero, paradoxical as this may sound; also many pregnancies will result in a normal instead of a pathological termination or complication by such treatment.

It is interesting to observe that in two cases where the mother had had marasmic children immediately before the last-born child, after the mother's mouth had been treated the next pregnancy resulted in a healthy child and no marasmus has supervened.

Cockspur-street, S.W.

THE VAGINAL PLUG.[1]

BY E. HASTINGS TWEEDY, F.R.C.P. IREL.,
ACTING MASTER, ROTUNDA HOSPITAL, DUBLIN.

THE treatment of ante-partum hæmorrhage by means of a vaginal plug is one of the oldest devices of surgery, yet it is within recent years only that the method of applying the plug has been properly understood. I remember hearing, when a student, my lecturer on obstetrics assert that he knew of no more efficient material for plugging than his silk pocket-handkerchief, and to illustrate his contention he took from his pocket an enormous scarf, dull red in colour and stained deeply by snuff and nasal secretion. I remember also an elderly doctor asserting that the family bath sponge made a most efficient vaginal plug. In my early professional days it was considered dangerous to introduce several small plugs lest some of them should be subsequently left in the vagina. It was to guard against this danger that the ridiculous kite-tailed arrangement was devised.

The subject of vaginal plugging was, however, seriously discussed only by the antiquated obstetrician, for the then modern one considered the method to be the most unsuccessful of futile manœuvres. At the present time one can hardly appreciate how great was the moral courage that enabled Sir William Smyly to become its advocate, and how keen and resentful was the opposition that his advocacy of it induced. The controversy has long since been forgotten, and statistics have proved that in its efficiency the plug has at present no rival.

The method as now practised depends for its efficiency on the capacity of the plug to push the lateral fornices of the vagina far up into the abdomen, so that they can be felt by abdominal palpation as hard rounded tumours situate well above the level of Poupart's ligaments. To plug efficiently the left hand should be passed into the vagina with the palmar surface directed towards the hollow of the sacrum, while the tips of the fingers lie behind the cervix. Small pieces of cotton-wool, squeezed out of lysol solution and each the size of the thumb knuckle, are then taken and inserted by means of the right hand round the cervix. The fingers of the left hand are kept busy squeezing the pellets into a compact mass and forcing the spaces between them to permit the insertion of still another plug. This process is continued in a systematic manner from above downwards till the vulva is reached and the vagina can hold no more. A T-bandage is applied to keep the plug in position, and an abdominal binder is fastened tightly from above downwards to press the side walls of the uterus against the vaginal dam, and thus completes the operation. A plug so applied will cause immediate cessation of hæmorrhage, and when it is removed after the lapse of hours so much blood only will be found as can be accounted for by the flow that took place during the operation.

Various explanations have been given of how the plug acts, and many of these by their ineptitude have greatly prejudiced the method of treatment. Many suppose that a back pressure on the blood-vessels is caused by the outpoured blood above the plug. This explanation is quite inadequate, and justifies Berkeley and Bonney in writing that "on first consideration the logic of plugging the vagina to arrest bleeding that is going on some distance above it may not appear obvious, yet its efficacy in cases with free external hæmorrhage is proven." These writers satisfy themselves that the efficacy of the plug depends on it increasing the power of the uterus to contract. When dealing with concealed accidental hæmorrhage, however, with the accompanying uterine inertia, they are driven to express a doubt whether the plug can have any directly useful effect. They say "it is easy to apply" and that it "has this great advantage, that it avoids rapid emptying of the uterus, a proceeding which always impresses severe shock on these patients. We think there can be no doubt that in some of these cases the bleeding has stopped by the time the practitioner comes on the scene, and that in such plugging the vagina has the great advantage of compelling him to pursue a course of masterly inactivity."

No doubt a plug applied in the method recommended by these writers will produce very different results from one applied in the way described above. They apply the plug with the aid of a speculum and a forceps, and use for this purpose rolls of cotton, each tied round with a string to facilitate removal. I feel sure it would not be possible to place in position one dozen of such rolls as are portrayed in their illustration. The plug, as I understand it, should consist of from 20 to 40 separate pieces, packed and dovetailed so closely into each other that they could not possibly be removed by pulling on them with a string.

I have quoted from the work of these writers to show how much, even now, the correct action of this device is misunderstood, and how much the method of treatment has suffered in consequence.

In 1898 I laid before this section of the Academy evidence to show that the plug acted directly as a compressor of the uterine vessels. Recently I have re-read that article and still cannot understand how anyone who took the trouble to weigh carefully the evidence I then adduced could have any doubt as to the truth of my contention. In the report of the discussion on that paper I find that, with the exception of Dr. Doyle, a general practitioner, all the speakers either ignored the suggestion altogether or treated it with contempt. It is therefore not surprising that the suggestion has not received general recognition in other countries. If truth could be destroyed by means of a studied boycott, assuredly this one would have shared that fate.

After nearly 20 years I am able now to bring forward positive proof that the plug acts in the way I have suggested. During the performance of several Cæsarean sections, after the delivery of the child and the stitching of the uterine wound, I have got an assistant to pass his hand into the vagina and to press it into the lateral fornix. In each instance his hand has formed a prominent convex tumour, which can be seen from the abdominal wound to press the base of the broad ligament upwards above the level of Poupart's ligament. On this tumour the uterine vessels lie, and I have been able to demonstrate to my colleagues, Sir William Smyly, Dr. Purefoy, and my Assistant Masters, that

[1] A paper read before the Obstetrical Section of the Royal Academy of Medicine in Ireland on April 20th.

the pulsation in these vessels is stopped by the pressure. On the last occasion I asked my assistant to tell the class what he felt. First he said the pulsation in the artery had ceased, and when I pressed the fundus of the uterus downwards to reproduce the conditions induced by the abdominal binder he said his finger had become nipped between the resistance below and the side wall of the uterus. If we remember the size and importance of the blood-vessels, both ovarian and uterine, which are situate in this region, the result of direct pressure exercised on them by a tightly fitting vaginal plug will at once become apparent.

In labour the opening of the internal os removes from the lateral fornices the support that it formerly afforded, and so allows the fornices to be pushed far up into the abdomen. In the non-pregnant state this cannot be done on account of the tightness of Mackenrodt's ligaments. These ligaments are really the tendons of the uterus. They are under the control of the uterine muscle fibres. It is the uterus by its inherent power, acting through these so-called ligaments and its other tendons, that forms the true floor of the pelvis. This is another truth of vital interest to the gynæcologist which I trust will not in its turn lie dormant for 20 years.

The vaginal plug is not easy to apply, nor is its application harmless. Sometimes, in spite of our best efforts, we cannot at the first attempt insert sufficient material to stop the bleeding. In such a case the plug must be removed entirely and then reinserted. On the second attempt the procedure will be found to have become much more easy on account of the dilatation of the vagina. Pain, distress, and some shock always follow from the application of the plug, and superficial tearing of the mucous membrane of the vagina is almost certain to occur.

It is clear that the words "vaginal plug" mean, in Dublin, something different from what they do elsewhere, and when one criticises the method of treatment one must bear the true meaning in mind.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF PLACENTA PRÆVIA AND TWINS.

BY W. GRAHAM REYNOLDS, M.R.C.S. ENG., L.R.C.P.LOND.;
AND
J. O. THOMSON, M.D. MCGILL,
SURGEONS, CANTON HOSPITAL.

OWING to its exceptional character, the following case may be worth recording.

The patient, a Chinese woman, aged 30, multipara, was sent into hospital with a history of there having been several severe gushes of blood. There had been no labour-pains, so that it was not possible to say when labour had started. Two previous confinements had terminated naturally. The patient was a strong healthy woman, of the farmer class. On examination the pulse was found to be strong and normal. The head was presenting; no fœtal heart was heard. Per vaginam the placenta was found to be centrally placed and the head presenting. The question of Cæsarean section was discussed and decided against, as the child was thought to be dead, and also we could not be sure as to who had examined previously. The os admitting two fingers and the cervix being soft and easily dilatable, it was thought that version and rapid delivery would offer the best chance for the mother, as, if there was any difficulty in delivery, perforation and extraction could be performed. Two fingers were accordingly introduced and bipolar version attempted; great difficulty, however, was experienced in turning the child. The cervix proving very easily dilatable, it was stretched with the fingers, the hole through the placenta enlarged, and a hand introduced, and first one and then the other leg was brought down. Quite gentle jaw traction was sufficient to deliver the after-coming head. The hand was reintroduced and the placenta removed. It was noticed, per abdomen, that after the child was born there was still a mass seemingly occupying the uterus. The hand introduced to peel off the placenta discovered a second fœtus, also with the head presenting. A leg was brought down and the fœtus delivered; there was a separate placenta, normally placed, which was delivered manually. The uterus contracted well, and the patient was returned to bed in good condition, not having lost much blood. The first child, though in a state of "white asphyxia," breathed well after some 15 minutes' artificial respiration had been done; the second child was quite dead, and had been so probably for a day or two. Both were males. The mother had a normal puerperium, and left the hospital with her child on the tenth day.

The chief points of interest in this case are the biocular twins, one placenta being normally placed and the other centrally over the internal os, and the ease with which the os dilated from the size of a florin to a size sufficient to admit of the passage of the first child. There was no tear either in the cervix or the vagina.

Canton, China.

CASE OF TETANUS TREATED BY INTRAMUSCULAR INJECTIONS OF ANTITOXIN.

BY G. H. V. APPLEBY, M.D., B.HY. DURH.,
ASSISTANT SURGEON, HARROGATE INFIRMARY.

IN view of the recent discussion of the methods of treatment of tetanus by antitoxin the following case may be of interest. The notes were taken by Mr. S. A. Faulkner, house surgeon, Chalmers Hospital, Edinburgh, and lately house surgeon, Harrogate Infirmary.

Patient was admitted to Harrogate Infirmary on Nov. 14th, 1916, suffering from a deep and jagged wound, 5 inches long, of the hypothenar eminence of left hand caused by a hay-chopper. The wound was dressed and the patient retained in hospital. No prophylactic injection of antitoxin. As wound was far from clean continuous eusol baths were ordered. On Nov. 23rd, ten days after admission, twitching of left leg with tonic contractions of both recti and slight opisthotonos. Patient was at once given antitoxin serum U.S.A., intramuscularly, 1500 units, and 20 c.c. of 10 per cent. sol. of mag. sulph. subcutaneously; these were continued during next five days. On Nov. 24th the symptoms were more pronounced; profuse sweating; risus sardonicus well marked and difficulty in swallowing. Temperature subnormal; it had been so after second day of admission and did not rise with onset of tetanic symptoms. Pulse remained about 80; respirations 24. On Nov. 28th temperature rose to 100° F.; pulse 100; respirations 28 and very laboured. Abdominal muscles contracted like a board. Patient was unable to swallow; clonic contractions of muscles of both legs and arms. Chloral hydrate was given per rectum, and antitoxin increased to 8000 units daily for three successive days (Nov. 28th, 29th, 30th). On Nov. 30th marked signs of improvement. Temperature normal; pulse 80; respirations 24 and less laboured. He could swallow, though with difficulty. Antitoxin again reduced to 1500 units, and continued daily together with injection of mag. sulph. until Dec. 20th. Patient continued to do well, the spasmodic contractions gradually abated, though the recti and abdominal muscles remained obstinately contracted well into convalescence and after the wound was soundly healed. He was discharged well on Jan. 3rd, 1917.

There is little doubt that in this case the initial doses of the antitoxin were too small, and that the very much increased doses had a quick and marked effect. Another point noticed was the persistence of the contraction of the abdominal muscles.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The annual general meeting of this society was held on May 18th, at 11, Chandos-street, W., Sir Alfred Pearce Gould, the President, being in the chair. From the annual report it appears that the invested capital of the society amounts to £140,000, and £4223 13*s.* 11*d.* were distributed during the year amongst the 48 widows and 9 orphans who are in receipt of grants. The working expenses amounted to about 4½ per cent. of the income, practically the whole of the income of the society being spent on the grants; but although nearly 7000 medical men are eligible for membership of the society, as residing within a 20-mile radius of Charing Cross, barely 300 are members. The President, commenting on this fact, said he quite realised that the young medical man just qualified thought he could never fail to rise to the top of his profession, but it only needed to attend the meetings of the court of directors to realise that in many instances these hopes were not attained.

Reviews and Notices of Books.

Medical Bacteriology. For Practitioners and Students. Edited by Dr. L. A. TARASSEVITCH. In three parts of 428, 700, and 200 pages respectively and an Atlas of Microphotographs in 16 plates. Petrograd and Kieff. 1912–1915. Price 17*s.* 8*d.*—This is a large text-book on bacteriology in Russian, to which 36 writers have contributed, including the preface by Professor Metchnikoff, the whole being under the editorship of Dr. Tarassevitch, of Moscow. Apart from the monumental work of Kolle and Wassermann, no other bacteriological treatise reaches the dimensions of Dr. Tarassevitch's work, which is original throughout. Each part is written by a specialist, and includes the best known Russian bacteriologists, such as Omelianskij, Tchistovitch, Wladimiroff, Zabolotny, and Korschun. Among the younger generation appear the names of Yakimoff, Klimenko, and Padlewsky. From the Pasteur Institute in Paris the Russian workers Besredka, Weinberg, Shoukevitch, and Romanovitch are important contributors. The life-history of all the pathogenic organisms is fully and critically described, and at the end of each chapter there is a general survey of the pathological lesions produced. Immunity reactions are exhaustively dealt with, the most recent phenomena in this involved field being adequately treated. Although some of the authors show a tendency to dogmatise a little more than is justifiable, it will be found in general that the work is excellently done. The supplement contains a special chapter on the infective diseases of plants and epizootics. It has been the aim of Dr. Tarassevitch to make the work exhaustive and at the same time practical, and he has succeeded in bringing out an eminently satisfactory text-book. Most encyclopædic works suffer from the defect that the various authors do not adopt the same methods of treating their respective subjects. In Tarassevitch's "Medical Bacteriology," however, a singular uniformity has been preserved. Although many Russian investigators have made great names for themselves during the bacteriological epoch in medicine this work in its completeness and magnitude will come rather as a surprise to a generation who has believed that it is only the German works that count, and it shows the high standard of medical intellectual culture in a country which has been to a large extent neglected in Western Europe. Accustomed to the high price of English medical books, the price of Dr. Tarassevitch's treatise must appear remarkable.

Les Fractures de l'Orbite par Projectiles de Guerre. By FELIX LAGRANGE, Professor in the Faculty of Medicine, Bordeaux. With 77 figures in the text and 6 plates. Paris: Masson et Cie. 1917. Pp. 222. Price 4 francs.—Professor Lagrange has written a very valuable précis of the war injuries to the eye under the misleading title, "Fractures of the Orbit." Many of his observations, which are founded upon an extensive experience at an important base hospital, are original, are discussed with a thorough knowledge of the pathology of the eye, and demand full recognition from ophthalmic surgeons. They are likely to overlook the importance of this small book, so inadequately described in the title, and it is therefore the more important to draw attention to the outstanding features of its contents.

Successive chapters deal with the surgical anatomy of the orbit, general considerations on the etiology of fractures of the orbit, fractures of the orbit with conservation of the eyeball, fractures of the orbit with destruction of the eyeball, treatment of orbital fractures, treatment of ocular complications, and reparative surgery. Many of the injuries of war, of course, resemble those met with in civil life, are due to similar causes, and require similar treatment. These are adequately discussed, with the citation of many illustrative cases, by Professor Lagrange. Of greater value are the original observations, the accuracy of which will for the most part be confirmed by the experience of British ophthalmologists. Thus it is pointed out that the direct injuries of war do not cause fractures of the roof of the orbit and implicate the optic foramen or sphenoidal fissure by irradiation, as is so commonly the case in fractures of the base of the skull in civilian life. The latter are generally caused by falls upon the head or severe blows directed downwards upon the vertex of the skull, injuries rarely met with in war. When the eye is directly struck by a projectile it is generally hopelessly disorganised. Slighter injuries are due either to the penetration of minute metallic fragments or to concussion. A projectile passing in the immediate vicinity of the eye causes severe injuries by concussion. Most of the ordinary effects of concussion, such as iridodialysis, traumatic cataract, dislocation of the lens, and so on, are frequently seen. Professor Lagrange has never seen an ordinary rupture of the globe in the intercalary region. We can confirm this observation, but possibly such cases do occur and the eyes are excised before the patients reach the base hospitals. Lagrange has seen many detachments of the retina, which does not altogether accord with our experience. He is certainly right in his remarks on the frequency of ruptures involving both retina and choroid. These are rare in civil life, whilst choroidal ruptures are common. Retino-choroidal ruptures are followed by the development of masses of cicatricial tissue in the fundus which are very familiar to those who have seen many war injuries of the eye. The repair of cicatrised and distorted sockets and of the ghastly ravages produced by war wounds of the face is one of the most trying tasks of the surgeons at the base. Professor Lagrange writes very enthusiastically of the value of fatty and cartilaginous grafts, especially of the latter. The book is admirably illustrated by very clear diagrams and excellent half-tone blocks of fundus conditions.

JOURNALS.

The Indian Journal of Medical Research. Vol. IV., No. 3.—This is a specially good number, and it is notable, moreover, for the beauty and excellence of its many coloured plates. It contains an abstract of the address delivered by Surgeon-General Sir Pardey Lukis before the Indian Section of the Royal Society of Arts, on the opportunities for medical research in India. Dr. R. Row, of the Petit Laboratory, Byculla, Bombay, describes a simplified technique devised by him of Bass's method of cultivating malarial parasites *in vitro*, along with some observations on the malarial parasites cultured by this technique. This paper is illustrated by seven coloured plates and numerous charts. A note on flagellate dysentery is contributed by Dr. S. C. Chatterjee, assistant professor of pathology at the Medical College, Calcutta (with five coloured plates). Captain H. E. Shortt furnishes notes on two hæmogregarines of cold-blooded vertebrates, illustrated by two coloured plates. The next two papers are by Major Clayton Lane in continuation of his previous work on intestinal parasites, the first relating to *Bunostomum kashinathi* and the Ankylostomidæ (with four plates); the second, a short paper, is entitled "Are *Echinostomum malayanum* and *Artyfechinostomum sufrartyfex* Identical?" The report of a special investigation conducted under the auspices of the Indian Research Fund Association, on dysentery in the jails of Eastern Bengal, is supplied jointly by Major J. Cunningham and Captain H. H. King. This contribution extends to 56 pages and is illustrated by photographs, maps, and charts. A study of entamœbic cysts is contributed by Captain R. Knowles, I.M.S., of the Bombay Bacteriological Laboratory, in conjunction with Captain A. F. Cole, R.A.M.C., of Cumbala War Hospital, Bombay. This paper is illustrated by four coloured plates and a number of charts and tables. Two editorials complete the number, the first dealing with a new species of Anopheline, *Myzorhynchus similis*, sent from the Malay Peninsula by Mr. Richardson, travelling entomologist, the second being a summary of current medical research in Germany, compiled from various German periodicals for the benefit of those workers in India who have a difficulty in obtaining current German literature in war time. This summary, among other things, deals with typhus, cholera, influenza, pyrexia of unknown origin, &c.

Revue de Chimiothérapie et de Médecine Générale. 1e ann. No. 1, Jan.-Févr., 1917. Rédaction: 2 rue de Rivoli, Paris.—We are asked by Dr. J. Laumonier, rédacteur-en-chef, to announce the issue of this review of chimiotherapy, a new science, we are told, "which Germans had accaparated for their own benefit," notwithstanding that two French physicians, Dr. Dujardin-Beaumetz and Dr. Bardet, had been, about 20 years ago, its true inventors. The number contains three abstracts from American journals, an article by Dr. Henri Bouquet on the present position of antitetanic sero-therapy, a review of the chimiotherapy of tuberculosis signed J. M., and chiefly dealing with cyanocuprol, and an original article by the editor on colloidal iodine furnished by Messrs. E. Viel and Co.

THE LANCET.

LONDON: SATURDAY, JUNE 2, 1917.

Heliotherapy.

FOR many years the Continental medical press has contained more or less scientific contributions on the subject of heliotherapy, and only the overpowering importance of all subjects connected with the war has preserved sun-treatment from the unbalanced puffs of the amateur physician in the lay press at home and abroad. But in the case of sun-treatment publicity has distinct advantages. Scientific heliotherapy is still in its infancy, and even the physicians best qualified to give an opinion admit that they are, so to speak, groping in the light, and that the element of empiricism in their procedure is still very great. Two recent discussions in Christiania and Gothenburg have clearly shown how insecure the scientific basis of heliotherapy still is. Some speakers in Christiania characterised the heliotherapy practised in certain quarters as but little more than a well-advertised business undertaking, and suggested that the flood of "before" and "after" illustrations was over-flowing and calculated to give the misleading impression that heliotherapy is a panacea. Other speakers joined issue over the physics of heliotherapy, and the opinions expressed as to the comparative value of sunlight and the various artificial lights were also conflicting. Nor need we be surprised at this, for even on small practical points in sun-treatment there are quite divergent views. Some authorities, for example, regard rapid bronzing of the skin as highly desirable and beneficial, while others see in excessive pigmentation a screen, depriving the body of some of the most valuable constituents of sunlight. Nothing but exhaustive observation can decide where truth lies.

But though stress on our ignorance of the processes occurring in the body as the results of insolation must be confessed, as well as the elementary character of heliotherapy as practised to-day, it would be unjust to ignore the recent pioneer work in this field by Dr. A. ROLLIER and others. ROLLIER, in particular, has earned our gratitude by elaborating a well-regulated system, by insisting on accuracy of dosage, by directing attention to idiosyncrasy of the individual, and by emphasising the dangers of indiscriminate practices. A perusal of his well-known and beautifully illustrated text-book, "Cure de Soleil," will convince the reader of the care with which ROLLIER hedges in his procedure. But the average patient no more dreams of taking his sun-baths according to medical prescription than of regulating his breakfast by other dictates than those of common-sense. Physicians at seaside resorts are familiar with the consequences of sun-bath orgies, for "beach fever" is no rare complaint in the holiday months. At the present stage it is urgently necessary that the dangers of heliotherapy should be recognised and preached; the antics of the crank are calculated to damn this valuable remedy more effectively than the most stodgy indifference. He is to be found by the score in every bathing resort, exposing to the sun by the hour his head and neck—the parts of the body most vulnerable to sunlight. Or, emerging from the shades of a London office, he starts his course of "heliotherapy" with several hours' exposure of most of his body. Little wonder if he returns to work a few weeks later listless and irritable, with a blistered skin and an aching brow. Some years ago a German writer called attention to the ill-effects of self-administered heliotherapy in an article in which he drew a well-defined clinical picture of nervous exhaustion and irritability. Many of our readers may be consulted concerning sun-treatment in the course of the next few weeks, in which case they will be well advised to recall the existence of quite serious conditions that may be induced by injudicious exposure to the rays of the sun.

The Swiss mountain health resorts offer admirable facilities for heliotherapy, and encouraging reports are coming in from other countries blessed with a less prodigal wealth of sunshine. In Norway, for example, heliotherapy has been adopted as part of the sanatorium régime by Dr. HOLMBOE at Mesnalien, and his verdict in cases of pulmonary tuberculosis in every stage when submitted to heliotherapy is favourable. The euphoria following the exposures was often so great, even in cases of advanced disease, that the patient was apt to exceed the prescribed limits. HOLMBOE adopts the cautious dosage recommended by ROLLIER in surgical tuberculosis, the first exposure being of the feet and ankles only and limited to a period of five minutes. In the course of about eight exposures he works up to a maximum of 4½ to 5 hours a day, the whole body, except the head, being treated. In this country heliotherapy has hitherto been at a discount. Yet it is not such a fog-bound island as the continental tradition would have it, and many a golden opportunity for turning the sun to account is undoubtedly lost. The institutions in which a properly planned solarium exists are, indeed, few; but it is to be hoped that when we emerge from this war heliotherapy will be introduced into the routine of sanatorium treatment. Already Mr. H. J. GAUVAIN[1] has shown at Alton that heliotherapy is a practical proposition in this country, and it is satisfactory to note that he is not blindly practising heliotherapy by rule of thumb, but is evolving and testing theories which may help to place this treatment on a more rational basis.

Medicinal Plants.

SERIOUS dislocation of important industries must always be reckoned among the inevitable results of hostilities in any part of the world, and it is only natural that efforts should be made to counterbalance and reduce the inconvenience at the earliest moment. While in this country the most pressing trouble lies in problems connected with

[1] THE LANCET, 1917, i., 663.

food-supply, the work of many surgeons, physicians, and pharmacists has been hampered by the war. Surgeons have found difficulty in replacing instruments, while physicians and pharmacists have similarly had trouble in making good the shortage of many synthetic remedies formerly derived from Germany. In addition there has been considerable inconvenience in pharmacy owing to the divergence into more important channels—munitions—of many articles previously largely employed in medicine. Therefore the supply of medicinal plants is attracting a great deal of attention at the present time, and we publish this week a note by a practical grower on their cultivation. The matter also formed the subject of a recent lecture at the Royal Society of Arts by Mr. J. C. SHENSTONE, F.L.S., and in the course of his remarks he emphasised the need of careful and continuous attention to scientific culture and economic organisation if herb-growing was to be of any real service to anybody. He admitted that much of the work would be of an experimental nature, to determine whether, under cultivation, the amount of active principle could be increased, though the value of home-grown medicinal plants might be much appreciated by war conditions.

To adapt ourselves to war conditions forms a part of the necessary process by which we all have to learn to share in helping to win the war. Manufacturing chemists have thus been stimulated to produce the equivalent of many synthetic remedies which were formerly imported, and it is to be hoped that in post-war conditions these new compounds will hold their ground against the inevitable foreign competition. The production of synthetic remedies must always remain in the hands of skilled pharmaceutical chemists, and it affords no outlet for the well-meaning efforts of the amateur. But the growing at home of medicinal plants was seen at once to give him a possible chance. Indeed, a promising field of energy was found in the attempt to popularise the collection and the cultivation of plants to be used as medicines. But the most earnest advocates of this movement admit regretfully that the number of indigenous plants officially recognised in this country is remarkably small, though they point to the plants used in France and in the United States as indicating that our employment of herbal remedies is unduly restricted, seeming to hope that an increased or varied supply of remedies will create a demand. Meanwhile it is realised that there are certain dangers in leaving the task of collecting in the hands of the untrained, and with a view to indicating where these dangers lie a charming little book on "Herbs Used in Medicine," with excellent coloured plates, has been published by the National Herb-Growing Association. Even in this small volume several plants which are not official are depicted, and the reader is referred to the two volumes, printed in 1790, of Dr. WOODVILLE'S "Medical Botany," with plates of all the medicinal plants then official. He will then see that it is possible that our whole outlook on the subject has been too narrow.

Undoubtedly very many vegetable drugs have been discarded since 1790. Remembering this, but knowing also that it has been prudence and not prejudice which has dictated the scientific attitude, we fear that an attempt to revive interest in home-grown pharmaceutical plants is doomed largely to disappointment. They have been tried and found wanting. Modern tendencies amongst medical men point to a form of treatment based upon an intimate knowledge of pharmacology, and the vegetable drugs which are retained in most instances have had to justify their existence as remedies by the presence of some definite alkaloid or active principle. If the activities of the National Herb-Growing Association are limited to the encouragement of an increased supply of herbs possessing alkaloids or active principles it is possible that a glut in the market may be produced speedily. On the other hand, it is very probable that, owing to improper methods of cultivation, a large amount of trouble will be expended without any corresponding advantage, as it is well known that medicinal plants require many peculiar conditions of soil and climate before they can attain the standard required by authority. With adequate care and knowledge these difficulties may be overcome, but the conditions cannot be met by enthusiasm alone. They demand special training and considerable expenditure, facts which were recognised by Mr. SHENSTONE in his lecture, in which he pleads for a Government Department entrusted with funds. We would not for a moment be found damping down the fires of a well-intentioned energy, but the article from a practical grower, to which we have already referred, reinforces Mr. SHENSTONE'S lesson that both money and expert knowledge are called for if the result of the growing of medicinal plants in this country is to be relative to the labour put forth.

Annotations.

"Ne quid nimis."

ATMOSPHERIC POLLUTION: A SENSIBLE GOVERNMENT GRANT.

THE Committee for the Investigation of Atmospheric Pollution has been constituted an "Advisory Committee on Atmospheric Pollution" to the Meteorological Office, and the advantages likely to result from obtaining a continuous record from year to year of the state of the atmosphere as regards suspended impurity have been recognised by a Government grant of £500, allotted by the Department of Scientific and Industrial Research, and designed to cover the cost of the work of the committee for the current year. The grant is intended to defray the expenditure of the Advisory Committee only, and was given on the understanding that the cost of gauges, collection, and analyses should be borne by the authorities which coöperate by setting up observing stations. Provision has been made for the nomination by each coöperating authority of a person for appointment as a member of the Advisory Committee. The action of the Department of Scientific and Industrial Research in making the grant was

only taken after full and careful consideration of the public advantages likely to accrue from the continuation of the work even during the war. At the same time, and since the value of the investigation depends on there being a sufficient number of observing stations, it was indicated that every effort should be made to maintain existing stations and to increase the scope of the movement, which has throughout received all the assistance which this journal could afford it. The collection, compilation, and publication of exact statistics on the suspended impurities of the air has a valuable function and supplements the study of all problems relating to fuel economy and smoke prevention. The reports for the years 1915–16 and 1916–17, forming the second and third annual reports of the committee, will shortly be published. Full information as to method of working at observation stations, with standardised instructions and blank forms for returns, can be obtained from the honorary secretary of the society, Dr. J. S. Owens, 47, Victoria-street, London, S.W. Since November, 1914, the returns in the form of a table, under the heading of "A Monthly Record of Atmospheric Pollution," have regularly appeared in our columns (those for the months of October and November, 1916, appear this week), and reprints are distributed to the committee and workers.

HYPOTHERMY AS AN EPILEPTIC EQUIVALENT.

IN the *Paris Médical* for May 12th, 1917, Dr. P. Carnot and Dr. A. de Kerdrel record a curious case coming under their observation at one of the neurological centres organised by the medical staff of the French Army.

The patient was a sergeant of the Chasseurs Alpins, aged 24, who was wounded on Sept. 16th, 1915, by a bullet which struck his forehead above the left eyebrow. Two hours later he was trephined. He is said to have remained unconscious for some 15 days, and on recovering his senses he found he was completely paralysed on the right side, but was able to speak. In the course of a month or more the hemiplegia gradually disappeared. Seven months after the date of the injury the patient suddenly had a fit of Jacksonian epilepsy, beginning in the right arm and becoming generalised; its duration was a quarter of an hour. Twenty-seven days later he had a second attack, beginning in the fingers of the right hand, and following the usual march up the arm and down the trunk and right leg. When he came under the observation of the writers he was seen to have a pulsating depression two finger-breadths above the outer end of the left eyebrow, pressure on which, however slight, produced an unpleasant feeling of malaise and painful radiating sensations referred to the right arm. There was slight general weakness of the right arm and slight diminution in sensibility in the same distribution. The rectal temperature was normal. A few days later a remarkable lowering of the temperature took place in a progressive fashion: from 36·7° C. (98° F.) it went gradually down in the course of three days to 34·4° C. (94° F.), rising again almost to normal in some 24 hours. Two days later another Jacksonian fit occurred of the same typical kind as before. On this occasion, however, repeated slight attacks also took place involving the right arm only, followed by paresis of the arm. On this occasion, further, the contractions in the arm were very painful, a condition which had not been remarked before. Some five or six days later the temperature began to fall again, and went down to 34·2° C. (93·5° F.), again gradually rising in the course of two or three days; a brief attack occurred at that time, influenced, no doubt, by the bromide treatment which had been instituted. This treatment also was responsible for the curtailing of a third phase of hypothermy and painful tingling in the right arm, without twitching, which developed some 14 days later. On the suggestion of Professor Sicard, in charge of the neurological centre, the patient's wound was reopened and the cicatrix was found to be adherent to the underlying gyri. It was completely freed, and thereafter the attacks of Jacksonian epilepsy and the hypothermy both ceased.

The question of heat "centres" in the nervous system is still the subject of much discussion among physiologists. Clinical evidence is abundant but conflicting. Cerebral lesions not infrequently produce a state of marked thermic disequilibrium. Sir William Gowers recorded a case of thrombosis of the basilar where the temperature rose to over 109° F., repeatedly verified. On the other hand, Janssen has reported a temperature of 87·2° F. in a case of general paralysis. Further, remarkable changes in body temperature occur after traumatic lesions of the spinal cord, and these vary with the level of the lesion, as has been shown by Gardiner and Pembrey in a series taken from the Guy's Hospital reports over a period of 50 years. There is, also, some evidence to suggest that in epilepsy an "attack" of hypothermy or hyperthermy may be of the nature of an epileptic discharge—an epileptic equivalent. In the present case the association between the two is curiously significant. The interpretation of these and other thermic phenomena may be difficult, but the subject is one deserving further study and investigation.

BACK TO THE LAND AND THE WAGES QUESTION.

THE National Housing and Town Planning Council has issued, in the form of a letter addressed to individual Members of Parliament, a pronouncement of its views upon the subject of the weekly wage contemplated for the agricultural labourer by the Corn Production Bill. Its main proposition is that the suggested minimum wage of 25*s.* is inadequate, and does not represent for the labourer an advantage corresponding to that offered to the farmer with the object of increasing the country's production of food. The Council does not put forward an amount to be substituted, but suggests that even the 30*s.* per week asked for by the National Agricultural Labourers' Union will prove insufficient. This opens up a serious prospect for those responsible for the national finances after the war, and for the promotion of agriculture under conditions to be brought about by statute, but as 25*s.* constitutes a rise of over 100 per cent. for the labourer in two counties, according to the statistics relied upon by the National Housing and Town Planning Council, and as in few areas will an increase of less than 100 per cent. be represented by a weekly wage of 30*s.*, it is clear that drastic reform is called for. The sums given as the "total earnings" of the labourer before the war, amounts which presumably include harvest money and like bonuses, will probably have to be raised by increasing these extra payments upon a scale corresponding with the increase in wages, for it can hardly be expected that they will be foregone, and their value as the rewards of industry will have depreciated as much as that of the weekly wage. The question of adequate agricultural wages will have to be faced and a decision arrived at, for the importance of it is evident, and the arguments put forward in the letter of the National Housing and Town Planning Council are clearly stated, whatever conclusion of assent or dissent be arrived at after perusing them. The aim of the legislator, in addition to that of providing for our future food-supply, will be to keep good workmen on the land and to tempt good workmen to return to it from the towns to which they have migrated, driven thither to a large extent by bad wages and bad housing accommodation in past generations—grave errors for which we are now about to pay. The matter of housing accommodation naturally receives prominence in the Council's letter, and from 5*s.* 8*d.* to 7*s.* 1*d.* are the weekly

rentals which it regards as necessary if cottages of a suitable character are not to be built at a loss to those providing them. The increased price of food and other commodities, together with the prospect of such prices being long maintained, is the other element in the calculation, and here also the National Housing and Town Planning Council presents a case deserving careful consideration by the legislature. The Council considers that the minimum wage proposed is inadequate, and that a degree of benefit is promised to the farmer which is denied to the labourer. That something short of the increase suggested by the Council's letter may be found adequate is possible, but it is of vital importance to bring the workman back to the land, to live there in healthy circumstances and to breed a stalwart race that will repair the ravages of war. To medical men, to eugenists, and indeed to all thinking persons it is inconceivable that such a policy should be defeated by the costliness of the means for attaining it.

HÆMATURIA FROM RIDING.

IN the *Medical Review* for May attention is drawn to a cause of hæmaturia which is not generally recognised—riding. This contingency is of special interest at the present time as the subjects were medical men who were learning to ride, evidently for the purpose of undertaking military work. Two cases have been recorded by different German writers. The first is reported by Grünbaum[1]:—

A medical man, aged 32 years, was given his first riding lesson on June 8th. The next day he rode for half an hour without stirrups on a rearing horse. About two hours later he noticed that his urine was scanty and of a reddish-brown colour. He also had the usual pains associated with the first riding lessons. He took a bath and about three hours later collapsed and had to go to bed. He was a perfectly healthy man, whose urine previously had been normal. Examination now showed 0·06 per cent. albumin, a few granular and hyaline casts and a few erythrocytes. On June 10th the albumin had increased to 0·1 per cent., and there were numerous granular and hyaline casts with a few erythrocytes. Next day, in addition to the constituents mentioned, leucocytes, epithelial cells, and a few epithelial and blood casts were demonstrable. On June 12th there was no longer any albumin and the number of formed elements was much reduced. On the 15th microscopic examination showed nothing abnormal. No renal symptoms, such as œdema or cardiac complications, were present, and there was no sign of any infectious or cardiac complaint. The hæmaturia was therefore regarded as due to concussion of the kidneys.

The second case is recorded by Gast,[2] who was himself the subject.

Unaccustomed to violent exercise, he took lessons in riding. The riding-master, a non-commissioned officer, at once forced the pace, making him trot without stirrups. After the first day he ached all over and on the following day did not ride for so long. On returning he noticed that the urine was very red. Innumerable red cells and a few casts and other formed elements were found. Suspecting that the hæmaturia was due to concussion, he spent the afternoon and night in bed and took a light diet. Next morning there was no macroscopic sign of blood, but under the microscope red cells were still demonstrable, as well as a few hyaline casts, but they were far less numerous than on the previous day. He did not lie up, and in the next few days all trace of albumin and blood disappeared. A few weeks later he resumed riding lessons under a more sensible master and began more cautiously. Though he continued the lessons for weeks the renal symptoms did not recur.

Gast refers to Grünbaum's case, and considers that both cases show that it is not necessary for a soldier who develops hæmaturia after the first hours of riding to give it up provided the hæmorrhage is due to concussion. These cases also show the folly of forcing the pace in a course of riding lessons, as is often done in Germany. The jolting of the whole body when stirrups are not used is so severe that unless the exercise is graduated there may be ill effects.

MEDICAL RESEARCH IN INDIA.

THE valuable paper read not long ago for Surgeon-General Sir Pardey Lukis by Sir Havelock Charles before the Indian Section of the Royal Society of Arts has drawn the attention of the medical public to the great progress which has been made in our knowledge of certain diseases in India, and also to the unrivalled opportunities afforded in that country for prosecuting medical research. He pointed out some of the many benefits conferred already upon mankind, especially in respect of tropical diseases, by Indian investigations. The discovery, for instance, of the spirillum of relapsing fever by Vandyke Carter at Bombay, opened out a new vista in connexion with the origin of specific fevers. The demonstration by Ross of the proteosoma parasite in birds, and his subsequent observation of a similar cycle of development of the malaria parasite, began a new era in the history of tropical medicine. Since then the detailed work carried out in India in connexion with the plague bacillus and the special investigations made concerning the cholera vibrio form valuable additions to the general stock of knowledge, and upon them have been based many of the practical measures formulated for the control and prevention of these diseases. No less important have been the recent contributions made in India in the field of scientific therapeutics, and in this connexion the methods of treatment of cholera, dysentery, kala-azar, and leprosy, recorded by Rogers in Calcutta, are deserving of special mention—examples which do not by any means exhaust the list. In the immediate future we may anticipate fresh discoveries as a result of the new research laboratories established in Bombay, Kasauli, and Madras. Two new schools of tropical medicine are being inaugurated at Bombay and Calcutta, and when the present world-wide war is over and the various professors and lecturers return to India from their military service it may confidently be expected that, by the education of native medical men in modern scientific methods of research, a fresh stimulus will be given to the investigation of those diseases of India the nature and origin of which are still obscure. The recruiting of the Indian Medical Service from the more highly qualified and earnest young practitioners of our own country may also be expected to assist, as in the past, in elucidating many medical problems in view of the special opportunities now afforded in India to competent investigators. The establishment in 1911 of the Indian Research Fund Association, generously endowed by Government, is likely to prove of great assistance to qualified experts who otherwise, on account of the cost, would be unable to carry out their protracted experiments. The *Indian Journal of Medical Research*, which is edited by the Director-General of the Indian Medical Service and the Sanitary Commissioner with the Government of India, and published by the Indian Research Fund Association, supplies a convenient and useful medium for making known to the scientific world the results obtained by these investigators. This journal is now in the fourth year of its publication, and already many important contributions have appeared in its pages relating to such subjects as malaria, plague, cholera, yellow fever, kala-azar, ankylostomiasis, dysentery, goitre, and leprosy, as well as the bacterial standards of tropical water-supplies, the cinchona derivatives, the flies and mosquitoes

of India, parasitic ticks, and the like. Some current investigations, we learn, have been interrupted by the war, but will be resumed as soon as peace is declared. In another column we notice the last issue, which is notable for its profuse and valuable illustrations.

A CASE OF PROGERIA.

PROGERIA is defined by Mr. Hastings Gilford[1] as "primary spontaneous infantilism mingled with premature senility." The premature senility is its most obvious feature, and only a few cases of it have been described. Dr. J. C. Schippers has recently reported[2] a new instance.

The patient, a boy weighing 6 lb. at birth (August, 1911), was the first child of healthy parents. He was fed at the breast for a time, but was always puny and had a disproportionately large skull with prominent veins on it. After the first year, when he had whooping-cough, his hair fell off; his first teeth appeared and he walked at 18 months, and at the age of 2 he talked. His mental faculties seemed normal, and he got on well with other children. Dr. Schippers first saw him in April, 1915; he was a slightly built child with a very large rounded forehead, brown ill-nourished skin, projecting eyes, bald and prominently veined head, slightly enlarged thyroid, and over-large joints. The thoracic and abdominal viscera seemed normal, and no evidence of arterio-sclerosis could be obtained; there was nothing found amiss with the nervous system or the urine. Examination of the blood showed slight anæmia, and over 9 per cent. of the white cells were eosinophiles. The head was 49 cm. in circumference, the chest 48 cm., and the child weighed 25 lb. Examination with the X rays showed a normal sella turcica and nothing abnormal about the ossification of the bones generally. Eighteen months later the child was seen again and was in much the same general condition. He was over 5 years of age, but the anterior fontanelle was still open; the head was 50 cm. in circumference, the height was 88 cm., the weight over 26 lb., and an Arneth blood-count gave normal results.

Dr. Schippers mentions as the chief features of this case the pigmentation and malnutrition of the skin, the prominence of the joints, the open anterior fontanelle, and the baldness, with greyness of the few remaining hairs. Photographs, indifferently reproduced, show the build, pigmentation, and aged look of the child; his facies recall that of the well-known case recorded by Mr. Hastings Gilford. Dr. Schippers discusses the pathogenesis of progeria, which remains obscure.

THE CENTRAL STATISTICAL BUREAU.

WE referred in our issue of May 19th to the vital statistics for 1915 at some length, for it is of the greatest interest to know how the first year of war affected the population as shown by official figures. The value of statistical information is to-day increasingly recognised, and we are glad to learn that for the future the Registrar-General will undertake the responsibility of furnishing local mortality statistics to the medical officers of health of the various sanitary authorities throughout the country. In this way they will receive an adequate record of vital statistics the trustworthiness of which is guaranteed by a Government department. That this important duty should be undertaken, as a matter of routine, by the central statistical bureau has always been the contention of THE LANCET, and it is hoped that the system, which was successfully inaugurated last year, may be continued permanently, with the abolition of overlapping. Indeed, adherence to former methods of estimating populations has been rendered impossible by conditions of war. Men of military age have been largely drafted to military training centres or have been sent abroad with the Army, and the remainder of the male adult population, as well as much of the female population, has migrated to an inordinate extent into areas other than those in which it had been enumerated in 1911. In these circumstances estimates, whether of total or local populations, on the basis of Census returns, were obviously inadmissible, and the National Register of 1915 became the best available substitute. The only local estimates attempted have been those of total civil populations in the several areas, based on the results obtained from the National Register. A new light on the difficulties encountered, as the result of war, in the estimation of local populations was supplied by Sir Bernard Mallet's presidential address to the Royal Statistical Society, which has been reprinted for private circulation. In this document, the extent to which local fluctuations affect the vital statistics of administrative areas is revealed in the statement, that "owing to the unprecedented dislocation of the population caused by the withdrawal of men of military age from civil life, and the demand for munition factories and war services, the data for calculating local birth-rates and death-rates with any approach to accuracy simply do not now exist." After acknowledging appreciatively the help already derived from national registration, he goes on to assert that, without annual revision, national registration can supply no basis for calculations in this and future years. Fortunately, however, the need for some kind of enumeration for statistical purposes, at the conclusion of war, is conceded by the majority of those whose judgment is entitled to respect.

POISONING BY RHUBARB LEAVES.

AT the resumed inquiry held by the Enfield coroner on Tuesday last into the death of a local minister of religion, Dr. B. H. Spilsbury, who made the necropsy, attributed the fatal issue to coma consequent on oxalic acid poisoning, the oxalic acid having been taken in the form of cooked rhubarb leaves. Mr. J. Webster, assistant analyst to the Home Office, stated that he had found oxalic acid in certain organs of the body and no traces of any other poison. Analysis of rhubarb leaves from the same ground as those eaten by the deceased showed the presence of calcium and potassium oxalates in quantity about 10 grains of each to the pound. Dr. Spilsbury characterised this quantity as a borderline amount sufficient to cause serious symptoms in certain people. The smallest recorded fatal dose of oxalic acid is given in text-books as 60 grains, and the soluble acid potassium salt is stated to be equally poisonous. Taken in concentrated form both act as violent irritants and quickly excite vomiting, by which some at least of the poison is expelled. Well diluted or taken with other food gastric irritation may be absent and nervous symptoms dominate the case, due to alteration of the calcium content of the blood. Combined with calcium oxalic acid is entirely inert. The coroner uttered a warning against the use of soda in cooking rhubarb stalks —an addition which has been recommended to neutralise the acidity and avoid the necessity of adding sugar—inasmuch as a soluble oxalate may be produced by its action. He might well have given the positive injunction to add a pinch of powdered chalk in the cooking, whereby the same end is attained with perfect safety.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

—o—

WEDNESDAY, MAY 23RD, AND THURSDAY, MAY 24TH.

THE Council resumed its sittings at its offices, 44, Hallam-street, W., Sir DONALD MACALISTER, the President, being in the chair.

Penal Cases.

The first case to be considered was that of Thomas Dixon Cook (adjourned from Nov. 29th, 1916[1]) on a charge of enabling certain uncertified women to attend women in childbirth in contravention of the Midwives Act, 1902.

At the conclusion of the hearing in November the President announced that the Council had found the facts alleged in the charge against the practitioner to be proved, but judgment was postponed until the present session.

Mr. Cook attended, and the complainants, the Central Midwives Board, were represented by Mr. J. Bertram, solicitor.

Mr. COOK made a brief statement in which he stated that since he appeared before the Council he had conducted his midwifery practice entirely in accord with the Council's requirements.

Testimonials from certain medical practitioners in Torquay were read stating that no fault was to be found with Mr. Cook's professional conduct since he appeared before the Council.

The PRESIDENT said: Mr. Cook, the Council having considered your assurances as to your future conduct and the testimony in your favour given by your professional brethren as to your conduct in the interval, does not see fit to direct the Registrar to erase your name from the Medical Register.

The next case was that of Edward White, registered as of 2, Green Park, Bath, L.S.A. Lond., 1893; M.R.C.S. Eng., 1900; L.R.C.P. Lond., 1900, who had been summoned to appear before the Council on a similar charge.

Mr. White attended, and the complainants, the Central Midwives Board, were represented by Mr. J. Bertram, solicitor.

Mr. BERTRAM, for the complainants, submitted three cases on which the complaint was framed. Mr. White, he stated, was not present at any of the deliveries, which were conducted by an uncertified woman, Mrs. Webb, and, as he was informed, the services rendered by the medical man of a medical kind were not very much more than perfunctory services. The engagement in all cases was not made by the patient or or behalf of the patient with the medical man, but was made by the uncertified woman, who said she would see that the doctor came.

Mr. WHITE addressed the Council on his own behalf and stated that he had no intention or desire to contravene the directions of the General Medical Council. It was quite true that Mrs. Webb was prosecuted, and he gave evidence in connexion with the three cases. His answer was that although he had not been present at the births, he had given his continued attendance subsequently. He had fully and carefully taken all the usual precautions and had kept in touch with the cases both by personal visit and by inquiries for about two weeks. In view of his continued attendances, he did not think he was "covering" an uncertified woman, and if he had done so, it had been done unintentionally. He was anxious to conduct his practice in conformity with the rules and wishes of the Council.

The PRESIDENT said: Mr. White, the Council has come to the conclusion that the facts alleged against you in the notice have been proved. These facts are that you by your assistance knowingly enabled Mrs. Elizabeth Webb, whose name had been removed by the Cental Midwives Board from the Roll of Midwives, to attend women in childbirth under cover or pretence that such women were attended or to be attended by you or by her under your direction, thereby enabling the said Mrs. Elizabeth Webb, in contravention of the Midwives Act, 1902, to practise as if she were certified thereunder. You so enabled her by notifying births, on her behalf, in cases attended by her, and by signing maternity benefit certificates which she was not qualified to sign. The Council, in the public interest, takes a very grave view of the danger which arises from a medical practitioner who lends his name for such a purpose, and "covers" the practice of unqualified persons, under whatever pretext they practise midwifery, and whatever may be his personal opinion as to their skill and capacity to attend women in labour. In order, however, to give you an opportunity of reconsidering your whole position in relation to this matter, the Council has postponed judgment in your case till the next session in November. Before that date you will be required to send to the Registrar of the Council the names of some of your professional brethren who may be willing to testify as to your character and conduct in the interval.

The next case was that of Henri Saturnin Hartley, registered as of 8, Sackville-street, Port of Spain, Trinidad, M.D. U.Laval, 1906, who had been summoned to appear before the Council on a charge of issuing certificates of successful vaccination without having seen, examined, or vaccinated the persons in question, and of having paid commission to the person who procured him to give the certificates.

The case was brought to the notice of the Council by the Medical Board of Trinidad.

Dr. Hartley attended in person and was accompanied by his counsel, Mr. J. H. Watts.

Mr. HARPER, the solicitor to the Council, explained the circumstances in which the charge was brought. The Medical Board of Trinidad held an inquiry into a charge practically identical with the one now brought forward, and as a result the practitioner's name was erased from the Medical Register of Trinidad. He read a petition by Dr. Hartley to the Medical Board of Trinidad for the restoration of his name to the Register of the colony which was refused.

Dr. HARTLEY gave evidence on his own behalf, denying the allegations.

At the conclusion of the hearing the PRESIDENT announced that the facts alleged against Dr. Hartley had not been proved to the satisfaction of the Council, and the complaint was accordingly dismissed.

The Council then considered the case of Andrew Robertson Dow, registered as of Silverhowe, College Park, N.W., M.B., Ch.B., 1902, U. Glasg., who had been summoned to appear before the Council on the following charge:—

That being a registered medical practitioner you were at the general session of the Central Criminal Court beginning on the 6th day of February, 1917, convicted of conspiring with other persons to defeat the provisions of the Military Service Acts, 1916, and were sentenced to nine months' imprisonment in the second division.

Mr. Robertson Dow attended and was represented by Mr. Ernest Wild, K.C., and Mr. Showell Cooper.

Mr. HARPER, the Council's solicitor, in bringing the case to the notice of the Council, put in the certificate of conviction. He said that the course which Mr. Dow had taken in the events which had led to the proceedings in court was to give three certificates to men who were seeking for total exemption from military service or to be placed in a lower category. In two cases these certificates stated that the man had been his patient for some time, which was contrary to fact.

Mr. ERNEST WILD, K.C., who addressed the Council on behalf of Mr. Dow, suggested that in the light of the small remuneration that Mr. Dow received for giving these certificates, and in the light of the diagnoses being honest diagnoses, he had been sufficiently punished for making a statement in the interest of his patients which was undoubtedly false. He appealed to the Council to give Mr. Dow one more chance.

The PRESIDENT (announcing the decision of the Council) said: Mr. Andrew Robertson Dow, I have to inform you that the Council have found it proved that you have been convicted of the misdemeanour alleged against you in the notice of inquiry and have directed the Registrar to erase your name from the Medical Register.

The Council adjourned.

FRIDAY, MAY 25TH, AND SATURDAY, MAY 26TH.

The Council resumed its sittings.

Penal Case.

The Council considered the case of Alfred Banks, registered as of Five Ways, Ryde, I. of W., M. 1891, F. 1893, R.C.S. Eng.; L.R.C.P. Lond., 1891, who had been summoned to appear before the Council on a charge of committing adultery with a patient whom he had been attending professionally.

Mr. Banks was not present, but he was represented by Mr. Hemmerde, K.C., and Mr. Le Bas. After hearing the case,

The PRESIDENT (intimating the decision of the Council) said: I have to announce that the facts alleged against Mr. Alfred Banks in the notice of inquiry have been proved to the satisfaction of the Council, and that the Council has adjudged Mr. Alfred Banks to have been guilty of infamous conduct in a professional respect and has directed the Registrar to erase from the Medical Register the name of Alfred Banks.

Reports of Committees.

Sir JOHN W. MOORE presented a report by the Public Health Committee on a new statistical table for the 10 years 1905–1914, giving the figures for the first examination and second examination for the qualifications in public health

[1] THE LANCET, 1916, ii., 987.

and on matters arising therefrom. The report stated that in the professional examinations held in 1916 for qualifications in sanitary science, public health, or State medicine the total number of candidates who presented themselves before all the examining bodies was 137. The figures for 1913 and 1914 were 626 and 589 respectively. These figures included both first and second or final examinations and passes and rejections. The report remarked that when now a qualification in medicine and surgery had been obtained there presented itself at once not merely an opening, but an urgent call, for the services of the new graduate for civil or military or naval work.

The report was formally received.

A report on exceptional cases was presented by the Students' Registration Committee.

The PRESIDENT submitted a report of the Pharmacopœia Committee. This report stated that the number of copies of the British Pharmacopœia, 1914, which were sold by the publishers between Nov. 26th, 1916, and May 19th, 1917, was 1099. The total number sold since May 20th, 1916, was thus about 28,134 copies. Of the second issue, published in May, 1915, about 450 remained in stock at the present date. The committee recommended that a third issue of 5000 copies should be ordered from the printers. The committee had had before them communications from a committee appointed by the Home Secretary to consider questions relating to economies in the use of drugs which, owing to the war, had become limited in supply. The communications referred in particular to official preparations containing glycerine and refined sugar. The committee recommended that the Council should delegate to them power to make on its behalf such official intimations on the subject as the existing conditions might render necessary. In briefly commenting on the terms of the report the President made reference to the restricted supply of sugar. It had been suggested to the committee that where possible there should be economy of sugar as an ingredient in preparations. If the Council would give the committee the power the latter would make temporary regulations.

The report with its recommendations was adopted.

A report of the Examination Committee was received on matters relating to the Apothecaries' Hall of Ireland.

Dr. KNOX moved the adoption of a recommendation of the committee to the effect—

That the Apothecaries' Hall be requested to continue to furnish the tables of exemptions from, and results of, examinations as heretofore, giving particulars of marks, and when the candidate had been previously examined by the Hall, and had passed some portion of the examination, the date of such examination. And that the report of Dr. William Taylor on the examinations held in December, 1916, be forwarded to the Apothecaries' Hall of Ireland for their information, with the request that they will favour the General Medical Council with any remarks they may desire to make, in time for the meeting of the Council in November, 1917.

Dr. MAGENNIS expressed the hope that the prolonged and exceptional inspections which he looked upon as persecution would not be continued.

The motion was agreed to.

Finance Committee's Report.

Mr. TOMES submitted the report of the Finance Committee, which showed that the income of the General and Branch Councils for the year ending Dec. 31st, 1916, was £7992 and the expenditure was £6997. That showed, said Mr. Tomes, that the financial position of the Council was satisfactory, and that there was a surplus of income over expenditure of about £1000. Owing to the conditions of the war there was considerable reason to anticipate that the next two years might be rather lean. The war had diminished the number of students who might take their qualification and registration, but later on the Council might hope to recover its receipts from the registrations which would take place in subsequent years. The Canadian medical men whose degrees and diplomas had been recognised here had to a material extent been absorbed in the Royal Army Medical Corps. Instead of registering some of them had taken it that being entitled to registration was the same thing as if they had actually registered.

The report was received.

Education Committee.

Dr. MACKAY intimated that the Education Committee did not bring forward a report this session. Last session certain changes as regards Latin were made in the preliminary examination which qualified for the universities. The question of Latin in the junior examination was remitted to the committee for further consideration. There was the question of the substitution of science for Latin in the junior school. The committee had been prepared to report on that subject, but the Government had appointed a committee to deal with the whole question of science teaching in secondary schools. In view of that fact the committee thought that it would be wiser not to bring forward the report now, but to hold it over to the next session.

Dental Representation on the Council.

Mr. THOMSON gave notice that at the next session of the Council he would move a motion in favour of legislation to secure direct representation of registered dentists on the General Medical Council.

Appointment of Committees.

The following committees were appointed:—

Examination Committee: Dr. Taylor, Dr. Elliot Smith, Dr. Caton, Dr. Russell, Dr. Cash, Dr. Norman Walker, Sir J. W. Moore, Sir Arthur Chance, and Dr. Kidd.

Education Committee: Dr. Norman Moore, Sir G. Philipson, Sir F. Champneys, Dr. Mackay, Mr. Hodsdon, Dr. Knox, Sir A. Chance, Sir B. Windle, and Dr. Dixon.

Public Health Committee: Sir A. Newsholme, Dr. Latimer, Mr. Verrall, Dr. Littlejohn, Dr. Cash, Dr. McVail, Sir J. W. Moore, Dr. Magennis, and Dr. Coey Bigger.

Dental Cases.

The Council, after consideration of a report of the Dental Committee referring to George Horatio Jones, who was registered in the Dentists Register on Oct. 8th, 1878, as "in practice on July 22nd, 1878," and whose address in the Register for the current year was Great Russell Mansions, Bloomsbury, London, W.C., directed the erasure of his name from the Dentists Register. The report had reference to certain advertisements.

The Council, after consideration of a report of the Dental Committee, directed the erasure from the Dentists Register of the name of James John Gordon Webster Clarke, who was registered on Dec. 24th, 1878, as "in practice on July 22nd, 1878," and whose address in the Register for the current year was 18, Waterloo Bridge-road, London, S.E.

The General Registrar.

Lieutenant-Colonel Norman C. King was reappointed general registrar.

The session then concluded.

THE CULTIVATION OF MEDICINAL PLANTS.

CONTRIBUTED BY A DRUG-GROWER.

THE communication from the National Health Insurance Commission for England to the Board of Agriculture quoted in the February number of the Board's *Journal* was useful in throwing the cold light of reasoned knowledge on a subject which has been largely dealt with by patriotic and enthusiastic amateurs. Even the leaflet 288 of the Board of Agriculture, on which much of the amateur herb-growing was based, seems to have been written and issued without very careful investigation of the subject. At all events, some of the important herb-growers in this country, who might be expected to know their own business and have actual knowledge of the practicability of the culture of most medicinal plants, were not asked by the Board for their opinion. On the other hand, before the Insurance Commissioners published their statement on the matter, they undertook very careful and thorough inquiries, the result of which is embodied in their communication to the Board of Agriculture.

Official and Non-official Plants.

In the first place, until the Insurance Commissioners' report appeared no attempt was made to differentiate between the drugs used in ordinary medical practice—i.e., the official B.P. drugs which are comparatively few in number, e.g., Belladonna, Hyoscyamus, Aconite, Taraxacum, Filix Mas, and Valerian—and the host of others which are used mainly by the so-called botanic druggists and herbalists, such as Agrimony, Mugwort, Wormwood, Betony, Figwort, and so forth. The Insurance Commissioners naturally devoted their attention to the official drugs, singling out from these four—viz., Belladonna, Hyoscyamus, Digitalis, and Colchicum—for serious consideration. All the other official medicinal plants which might conceivably be grown or collected in this country can be dismissed in a few words.

Aconite.—Its cultivation has probably never paid in England, and at the present time it is possible to secure an ample supply at prices not greatly in excess of the pre-war figure, large quantities having been imported from Spain.

Dandelion (Taraxacum) cannot possibly pay to cultivate, nor is it necessary to do so as it is so common a weed. The grubbing of the root is a toilsome and dirty occupation, unsuited for the usual amateur herb-collector. While the greater part of the supply of dandelion root is used for non-official purposes, there has been ample available for the preparation of the official extract and juice. Last autumn one firm alone received from the collectors 5 to 10 tons a week.

Couch grass (Agropyrum) is present in quantities in most arable fields, and large quantities are readily available if required. The amount used in medicine is trivial.

Male fern (*Filix mas*).—With this a curious difficulty has arisen. Manufacturers using English root have found themselves unable to produce an extract containing the proper proportion of filicin; the B.P. requires not less than 20 per cent. Possibly the English root does not contain as much of this principle as the continental owing to climatic conditions, or the root may have been gathered at the wrong season of the year. At a recent drug sale more than 20 bales of this root were offered but found no bidder.

Chamomile and Valerian.—Before the war the supplies came mainly from Belgium, and these will presumably be again available later. In the meantime, recourse has been taken to the Japanese product from a different species, stronger than the European variety, and to an Indian species which is also official.

There remain the four essential medicinal plants to which the Insurance Commissioners direct attention. Of these, there is no manner of doubt that the supply of wild *Digitalis* and *Colchicum* is sufficient. With the former the only difficulty is proper drying, but a little experience will be likely to ensure a good result. *Colchicum* is present abundantly in this country, but its harvesting presents one practical difficulty. It affects the best pastures, and as it must be dug in summer serious damage is done to the grass, farmers naturally requiring substantial compensation for their loss. This and the scarcity of labour make the present price very high.

Belladonna is, of course, far the most important of the four, and while great scarcity and famine prices have largely prevailed, large quantities are now under cultivation and ample supplies will probably be available this summer and certainly next, not only for the use of the medical profession at home, but also for export.

Hyoscyamus usually commands good prices, generally better than Belladonna, but it is a very uncertain crop and liable to attacks by insect pests which in some seasons completely destroy acres of plants in a few days. Occasionally it produces very heavy crops and is then decidedly profitable, but such years are rare, and between them will be many lean ones and some absolute failures. Its cultivation is therefore hardly suited to anyone of small means to whom a crop failure would be a serious matter.

The Difficulties of the Small Cultivator.

The prudent will bear in mind the experience with lavender 20 years ago. The great frost of 1895 destroyed a large proportion of the lavender plantations and misleading reports were published about a "dying English industry." The late Sir W. Gilbey interested himself in the matter, with the result that so much was produced within the next few years that the price dropped to a ruinously low figure, entailing much loss to the growers. In the cultivation of Belladonna, growers who are also manufacturers have an advantage over those who are growers only in being able to judge their own requirements and lay down a corresponding acreage of the plant. Certain British herb-growers have now five or six times as much land under medicinal crops as two years ago and expect to be entirely independent of outside supplies this summer. Large growers are in a position to employ up-to-date and extensive drying apparatus, and in this and other ways are at an advantage over the small grower, to whom, therefore, the caution of the Board of Agriculture may not be out of place. For the cultivator of an acre or two the provision of suitable drying plant, used only for a short period each year, is an expensive item. In a large business parts, if not all, of the drying plant can be used nearly all the year for one purpose or another. Unless, too, the small cultivator definitely secures a customer for his prospective crop at a fixed price before he sows it he runs a risk of not being able to sell at all. Unlike corn and potatoes, for which there is only too ready a market, the moment the demand for medicinal crops is met (and the demand is strictly limited) the crop becomes unsaleable.

The Collection of Wild Plants.

From a business point of view a safer outlet for the energies of the amateur drug-producer is in the collection of wild plants, remembering that, for the most part, these are used by herbalists. As soon as the supply is sufficient the collector ceases operations, and hence does not accumulate more than he can sell. The occupation, although healthy, is rather humdrum as well as toilsome. It should also be regarded as a war-time measure. Many of these drugs grow wild in parts of the world other than the Central Empires. France, Spain, Italy, Russia, India, and Japan produce much already, and will probably send more in the future. Such "crude" drugs are the raw material of the drug manufacturer, and, along with other raw materials, have not hitherto been considered a suitable object for a protective tariff.

A MONTHLY RECORD OF ATMOSPHERIC POLLUTION.

COMMITTEE FOR THE INVESTIGATION OF ATMOSPHERIC POLLUTION: SUMMARY OF REPORTS FOR THE MONTHS ENDING

Oct. 31st, 1916.

Place.	Rainfall in millimetres.	Metric tons of deposit per square kilometre. Insoluble matter. Tar.	Carbonaceous other than tar	Ash	Soluble matter. Loss on ignition	Ash.	Total solids.	Included in soluble matter. Sulphate as (SO_3).	Chlorine (Cl).	Ammonia (NH_3).

* Owing to frost no returns were available at Victoria Park and Wandsworth Common. At Exeter and Malvern observations have been discontinued owing to the war.

"Tar" includes all matter insoluble in water but soluble in CS_2. "Carbonaceous" includes all combustible matter insoluble in water and in CS_2. "Insoluble ash" includes all earthy matter, fuel, ash, &c. One metric ton per sq. kilometre is equivalent to: (*a*) Approx. 9lb. per acre; (*b*) 2 56 English tons per sq. mile; (*c*) one gramme per sq. metre; (*d*) 1/1000 millimetre of rainfall.

The personnel of public health authorities concerned in the supervision of these examinations and of the analytical work involved remains the same as published in previous tables.

THE JOINT MEDICAL CONFERENCE IN CHINA.

(FROM OUR OWN CORRESPONDENT.)

THE Joint Medical Conference, which was held in Canton from Jan. 24th to 31st of this year, will long be remembered not only for its great success but also as the first real attempt made by Chinese and foreign medical men to join forces in this land. It may be remembered that the National Medical Association, consisting of modern-trained Chinese medical men, was formed in Shanghai just over two years ago. Last year THE LANCET published the proceedings of its first Conference held in Shanghai, where, among other things, it was decided to hold the Conference of 1917 in Canton in conjunction with the China Medical Missionary Association. The membership of the Missionary Association is about 450 and that of the National Association close on 500. There were 64 foreign and 92 Chinese doctors present, including 34 women.

The organisers in Canton did all they could to establish a record. Both Chinese and foreign doctors formed strong committees and enlisted the powerful support of the Civil Governor of the province, Chu Ching Lan. Good as his record had been as an enlightened and democratic official, no one expected that the Governor would go out of his way so much to promote the success of the Conference. His Excellency not only attended the opening reception on the evening of Jan. 24th, but he entertained all the delegates and their wives, numbering 170 persons, to a banquet on the roof garden of the leading Chinese hotel, opened the public health campaign in the city, and personally conducted the delegates in two yachts to the historic suburb of Whampoo on the Canton River for a picnic. No wonder the foreign guests expressed a hope that Governor Chu (who is only 42) would become one day President of China, as ensuring the rapid headway of medical science.

Papers Read.

The President of the Medical Missionary Association was Dr. W. H. Venable, of Kashing, while that of the National Association was Dr. Wu Lien-Teh (G. L. Tuck) of plague fame. Sessions were held in the morning and afternoon and on two occasions in the evening as well, Dr. Venable and Dr. Wu presiding on alternate days.

The most interesting papers read were as follows:—

1. *Standardisation in Mission Hospital Work*, by Dr. H. S. Houghton, who referred to the waste incurred in a medical man having to keep books, watch the market quotations, plan the building of hospitals, and generally look after affairs which could with greater economy be done by other men. He laid emphasis upon the need for proper staffing and management, keeping records and skilful nursing. He advocated standardisation in statistics and accounts. All financial records should embody clearly administration, maintenance, capital expense, and purchasing. There should be a central purchasing agency for all hospitals, situated preferably in Shanghai.

2. *Medical Schools in China*, by Dr. H. H. Hume (Johns Hopkins and Changsha), who classified them according to provinces, cities, date of foundation, and language taught. He enumerated 26 colleges altogether in the country, some missionary, some under the Chinese Government, some private, some joint foreign and Chinese, and two purely female institutions. The largest in point of numbers was the Army Medical College in Tientsin, with nearly 350 students, while the best equipped, with the possible exception of Hong-Kong which he had not visited, was the German Medical College at Shanghai, where students received a preliminary language training of three years and a professional training of four years. The total number of medical students in China at this moment was under 1500, of whom 136 were women—a very small number.

3. *The Nature of Plague Proteotoxins*, by Dr. Fred. Eberson, bacteriologist of the Manchurian Plague Prevention Service. These researches, undertaken to discover a serum for plague more potent than any, dealt with the peculiar nature of the proteotoxin of *Bacillus pestis*, which is unlike that of *B. typhosus*. Dr. Eberson's conclusions are: (*a*) Powerful shock-producing poisons can be obtained by allowing normal guinea-pig or horse serum to act upon sensitised plague bacilli. (*b*) The proteotoxins of *B. pestis* are thermostabile, resisting prolonged heating at temperatures ranging from 50°-61° C. (*c*) A wide range exists within which the poisons may be obtained. The essential requirement is sufficient sensitisation of the plague organisms. (*d*) Proteotoxins are obtainable even after considerable exposures, the average being 14 hours, sometimes 18 hours. (*e*) The mechanism of plague infection seems to depend upon a primary sensitisation of the organisms, the antigen-sensitiser complex being important for poison production.

4. *Placenta Prævia*, by Dr. R. W. Gibson (Hong-Kong). He enumerated the dangers of this serious complication in childbirth and produced statistics to show that it was more common among Chinese primiparæ than among Europeans, the proportion being 17 per cent. to 4·4 per cent. These cases were always serious for both mother and child, and occurred in the seventh to eighth month of intra-uterine life. He advocated podalic version, and a brisk discussion ensued.

5. *Spinal Anæsthesia Produced by Tropacocaine.*—Dr. Cheng Ho (Canton) described the technique and enumerated a considerable number of major operations which he had done by this method. He recommended its general use where general anæsthesia was dangerous—e.g., in cases of heart or lung trouble.

6. *The Menace of Morphine*, by Dr. Wu Lien-Teh, who drew attention to the enormous increase in the output of morphine from British firms in Great Britain and its smuggling by Japanese agencies into China. In 1911 the declared export from Great Britain was 208,540 ounces, or 5½ tons; in 1914 this had increased to 504,020, or 14 tons. He urged everyone present to support a resolution to be sent to the Chinese and British Governments and other medical bodies to act without delay upon the articles of the Hague Opium Convention signed on Jan. 23rd, 1912.[1]

7. *Diabetes*, by Dr. H. G. Earle, of Hong-Kong University, who after outlining the various theories of its causation, invited discussion on its treatment. He himself considered absolute starvation the best. In this he was supported by other speakers.

8. *The Work of the China Medical Board of the Rockefeller Foundation*, by Mr. R. S. Greene, resident director of the Foundation in China. He outlined the work in various educational centres, including two large medical schools in Peking and Shanghai, and the considerable financial support accorded to the Union Medical College at Tsinanfu, Red Cross Hospital (Shanghai), Changsha and Canton, as well as the foundation of scholarships and fellowships to Chinese and foreign doctors, pharmacists, and nurses. The assistance rendered by the Rockefeller Foundation to medical education in China has been very considerable during its three years' activity in China.

Other Proceedings.

The Research Committee reported what had been accomplished during the last two years. This comprised work done on "Pelvic Measurement," "Height, Weight, and Chest Measurements," "The Circulation," and "Normal Blood." This attempt to find a normal or physiological standard among Chinese may become very valuable; already much good work in a similar direction has been conducted by a physiological chemist in Tsinanfu on "The Diet of Chinese." Such investigations as this and as those so excellently carried on by the Plague Prevention Service show how progressive the study of medicine is becoming in China.

Considerable interest was aroused by the presidential address delivered by Dr. Wu Lien-Teh on "Some Problems before the Medical Profession in China." He alluded to the prevailing ideas among the conservative Chinese regarding the medical profession, and said that the Japanese were trying more to adapt Western medical science to the needs of the people, and that it was necessary for their Western colleagues not to fall behind. He advocated the formation without delay of a Central Medical Council corresponding to the General Medical Council of Great Britain, with functions similar to those possessed by that body.

Two resolutions were passed in joint session of the Conference, the first drawing the attention of the Government to the need of adopting measures to prevent the morphine habit, and the second to the need of the establishment of a Central Medical Council in Peking, whose duties should be the fixation of a minimum standard of general education, the maintenance of a student and medical register, the drawing-up of laws and regulations affecting the medical profession, and the adoption of a medical nomenclature in Chinese.

The Conference terminated on Jan. 31st, after an election of officers for the next two years. The new President of the Medical Missionary Association is Mr. C. J. Davenport, F.R.C.S. Eng., surgeon to the Shantung-road Hospital, Shanghai, while Dr. Wu Lien-Teh was re-elected for a further term of two years as President of the National Association. The next place of meeting will be Peking, in 1919. There is no doubt that a joint conference is the ideal to be aimed at by those who wish to see medical science make rapid headway. Both sides can mutually help one another, and there is every evidence that the next two years will see even greater progress.

Canton, March 16th.

[1] We hope to publish a fuller note on this paper.

THE annual general meeting of the South London Hospital for Women, Clapham Common, will be held at 5, Carlton House Terrace, S.W., on Wednesday, June 6th, at 3.15 P.M. The Marchioness of Londonderry will preside, and among the speakers will be Dr. Lina Potter, who will give her experiences in Russia, and Dr. Jane Walker.

HOSPITAL DISPENSER FOR 49 YEARS.—The death occurred recently at Shoreham of Mr. E. Fenner, who for 49 years was dispenser at the Royal Sussex County Hospital at Brighton. On his retirement from the office the governors, as a mark of their appreciation of his work, elected him a life governor of the hospital. His only son, a captain in the veterinary service, succumbed to wounds while in captivity during the South African War.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Welfare of Mothers and Children in Ireland.

A REPORT on the physical welfare of mothers and children in Ireland has been compiled for the Carnegie United Kingdom Trustees by Dr. E. Coey Bigger, the Medical Commissioner of the Local Government Board for Ireland, and was issued last week. It is an exhaustive and acute study of the causes underlying maternal and infantile disease and mortality, together with suggestions for improvement of present conditions. It gains added force from the strong feelings which have inspired the author. Dr. Bigger points out the special importance of the subject at present, when so many of the healthiest and fittest of our manhood, those who should be the fathers of the next generation, are losing their lives on the battle-fields of Europe. "The newly-born infant has less chance of living till this time next year than his father who is fighting out in France." It is true that the infant death-rate in Ireland—92 per 1000 births—is lower than that in England (110) or in Scotland (126), but whereas the rate in England has been steadily falling for many years past, in Ireland there has been little improvement. Dr. Bigger gives a table showing the geographical distribution of infant mortality, and from this it appears that in no less than eight counties the infant mortality is less than 60 per 1000. In only three counties—Antrim, Kildare, and Dublin—is the mortality over 100 per 1000. In each of the six county boroughs, however, the mortality is high, ranging from 108 in Limerick to 160 in Dublin. The greatest mortality is in the first few weeks of life, as, for example, in the Dublin registration area, where almost exactly one-third of the total deaths in the first year occur in the first month. From this fact it is clear that any scheme to diminish infant mortality must include consideration both of the health of expectant mothers and of the conditions under which child-birth takes place. Dr. Bigger gives reasons for believing that the most fatal of infantile diseases are bronchitis and pneumonia, the next group being diarrhœa and enteritis. Bronchitis and pneumonia would seem to be diseases that could be fairly readily prevented if mothers were better educated as to the means of preserving the health of their children.

The average puerperal death-rate for the past ten years has been a little over 2 per 1000 births. There is no Midwives Act in force in Ireland, and many of the confinements are attended only by "handy women." A marked proof of the value of skilled attendance at childbirth is shown by the fact that whereas the maternal death-rate in Dublin was 4·5 per 1000 in 1915, the rate among the patients attended by the Rotunda Hospital was only 2·3 per 1000. In giving this contrast its full value it is to be remembered that the Rotunda Hospital cases included many sent to the hospital on account of difficulties or complications.

Dr. Bigger has made a study of the economic conditions of working-class families, and he shows that before the war the wage of the agricultural labourer varied from 11*s.* to 15*s.* a week, while the average wage of the unskilled labourer in Dublin was 16*s.* 7½*d.* On such a wage it was impossible to support a wife and family in health. He adds:—

The tenement system of housing is largely responsible for the high mortality in the towns, because of the scanty water-supply, bad sanitation, and overcrowding of these tenement houses, which are mostly let in one- or two-room dwellings. That better housing can effect an enormous reduction in infant mortality is proved by the statistics of the Peabody Buildings in London. In these the density of the population was 504 persons per acre, but only 1·8 per room, and the infant mortality rate in them was 92 per 1000 when the rate for London was 120. It is therefore domestic not municipal overcrowding that is the important factor.

In parts of the North-East of Ireland it is the custom for girls to work as "half-timers" in the spinning-mills from the age of 12. These girls learn nothing of housecraft, and their health is bound to suffer from work at such a tender age. They often marry early. "Is it any wonder," says Dr. Bigger, "that a large proportion of the children of such mothers either die or are permanently disabled? ..... The manufacturers who employ 'half-timers' are contributing to the perpetuation of a great national wrong which cries aloud for redress."

I do not try to follow Dr. Bigger through the entire report, but I quote some of the more important of the recommendations with which he concludes:—

(1) A Midwives Act for Ireland; (2) schemes for the instruction of expectant and nursing mothers, and the establishment of infant and child-welfare centres; (3) the extension of the boarding-out system and the detention of mothers of illegitimate children for at least three months; (4) the extension of the Provision of Meals Act to rural districts, and a grant-in-aid from the Treasury for that purpose; (5) a scheme for the medical inspection of school children; (6) the raising of the age of girls allowed to work in factories to 15 years, and the establishment of a system of full-time medical officers of health; (7) improvement of housing conditions, the abolition of slums, and power to urban district councils to provide houses for the poorer working classes; (8) the establishment of milk depôts and more vigorous and uniform enforcement of the Dairies, Cowsheds, and Milkshops Order of 1908, with provision in large towns for bacteriological tests for the detection of tubercle bacilli in milk; (9) State-aid for parents of the poorer classes as a grant for each child.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Duration of War-deafness.

THE term war-deafness has been given to the deficiencies of hearing produced by the sudden change of pressure when a projectile of large calibre explodes. Three kinds of lesions have been distinguished affecting: (1) the middle ear alone (18 per cent.); (2) the middle and internal ear (57 per cent.); (3) the internal ear alone (25 per cent.). In the last case the injury leaves no visible effect. It has been said that 98 per cent. of these cases of deafness recover spontaneously; but Dr. Marage has recently brought before the Academy of Sciences evidence to show that this is not true, for lesions of the middle ear leave behind, after clinical recovery, more or less pronounced deafness which impairs the efficiency of officers, non-commissioned officers, and telephonists. In the 25 per cent. of cases of deafness due to disturbances of the internal ear without apparent lesions spontaneous recovery should be shown by an increase of auditory acuity proportional to the length of time since the injury was received. This was not the case. In 150 cases of deafness of 2–14 months' duration investigated by Dr. Marage the average of auditory acuity remained equally bad whatever the date of the lesion. Re-education is therefore an imperative need for these cases.

Intrascapular Fracture of the Hip Treated by Grafting.

M. Pierre Delbet reported recently to the Academy of Medicine on the results in fracture and pseudarthrosis of the neck of the femur treated by a method of his own. While extra-articular fractures when suitably treated consolidated by formation of bony callus leaving only slight weakness, intra-articular fractures through the surgical neck or with complete separation of the head resulted in pseudarthrosis with more or less complete disablement. This was the more regrettable since, contrary to accepted theory, intra-articular fracture was the rule among young people. Hitherto no satisfactory treatment has been devised. M. Delbet employs grafts of 6½ cm. to 11 cm. in length, according to the size of the neck of the femur, completely stripped of periosteum and becoming actually part of the living bone. Proof of this was furnished not only by successive radiographs made over a period of 2–3 years, but also by the fact that the separate portions of broken grafts became consolidated. The rapidity of the restoration of function after operation depended on the duration of the pseudarthrosis and the extent of the secondary muscular atrophy. The duration of the disablement was much reduced in patients thus treated at the outset, and M. Delbet estimates that in future it should not exceed that in ordinary fracture of the femur. The long duration of pseudarthrosis is a troublesome factor, inasmuch as it renders regeneration of bone difficult, if not impossible, and because the absorption of bone which has occurred by enlarging the space between the fragments necessitates a larger graft and exposes it to the risk of breaking. Delay does not, however, constitute an absolute contra-indication to operation. Nor is age in itself a drawback. Of the 15 cases treated by M. Delbet one must be excluded, that of a much debilitated woman of

66 years who became paralytic in the course of treatment. Of the remaining 14 cases, only one failed to derive benefit—namely, a woman of 59 years, excessively obese, suffering from multiple dry arthritis, who died within a year of operation without regaining her ability to walk. The 13 other patients are walking, three of them still improving. One of these, operated upon three months ago, already walks so well that reasonable doubt might arise as to the existence of a fracture. Another, operated upon four months ago, cannot yet dispense with a stick. The same is the case with a woman who has fractured her graft.

Trench Hemeralopia.

In a communication to the Academy of Medicine M. Aubaret noted that while disturbances of vision at night are fairly frequent at the front the number of cases of true hemeralopia is relatively small. The distinction of pseudo-hemeralopia from true hemeralopia is not difficult. True hemeralopia appears in several forms according to the site of insufficient adaptation—pupillary (a fairly frequent form), retinal, or cerebral. Cases of insufficient adaptation were found amenable to treatment with atropine. For faulty retinal or cerebral adaptation smoked glasses of a fairly high degree of obscurity, Nos. 4–5, worn during the daytime were found of service. In all doubtful cases of hemeralopia care should be taken to improve the general condition; physical and mental rest, the exhibition of tonics and reconstituents, and a routine of diet conducive to the elimination of toxins are the measures indicated.

Obituary.

MAJOR GREENWOOD, SEN., M.D. BRUX., L.R.C.P. LOND., M.R.C.S. ENG., D.P.H., LL.B. LOND.

Major Greenwood, the deputy coroner for North-East London, who died on May 16th, aged 63, in Hackney, where he had long resided, came of a family which had long been established in the East-End of London. He was the son of the late Dr. Major Greenwood of Dalston, and was educated at the Merchant Taylors' School, whence, in 1873, he obtained a Buxton scholarship at the London Hospital. He qualified in 1876, taking the M.R.C.S. Eng., and the L.R.C.P. Lond. in the following year, and held various resident appointments at the hospital. Later he became resident medical officer to the North-Eastern Hospital for Children, now the Queen's Hospital for Children, and on leaving this appointment he settled down to general practice first in Dalston and later in Hackney. But at the same time he displayed his energetic temperament by joining Lincoln's Inn and reading for the Bar. In 1887 he took the M.D. of Brussels and in the same year the D.P.H. of the Conjoint Board, and in 1894, having been called to the Bar, he took the LL.B. Lond.

The mere enumeration of Dr. Greenwood's appointments will show how active he was professionally, politically, and socially. He was, in addition to being a busy medical man and a deputy coroner, senior district surgeon to the City of London Lying-in Hospital, public vaccinator for Haggerston and medical officer for No. 5 District of St. Leonard, Shoreditch, medical officer to King Edward's Industrial School, treasurer of the Brussels Medical Graduates' Association, secretary of the Poor-law Medical Officers' Association, Vice-President of the Medical Defence Union, and a member of the Central Council and President of the Metropolitan Counties Branch of the British Medical Association. In the activities of the British Medical Association he played a valuable part in many capacities.

Major Greenwood was a voluminous writer along lines of widely differing directions. He was the editor of *Poor Law Supplement*, the author of monographs on zoology and vaccination, and of essays on the Great Plague of London and other subjects of historical and literary interest. He obtained a prize in 1894 for an essay in the *Law Students' Journal* upon the Responsibility of Judges, and in the same year he published a note summarising the claims of the two professions, law and medicine, on the coronership. He wrote also an exposition of the Law Relating to Poor-law Medical Service, and a story of medical life, entitled "John Armstrong." It will be gathered that Major Greenwood was an exceedingly busy man, and all the numerous public and private claims upon his time received from him just acknowledgment. His wide experience, courage, and industry earned for him the regard of the large section of the medical profession to whom he was known personally or through his works, and where controversy ran high in medical politics he allowed no personal feelings either to mar his relations with opponents or to diminish his zeal in the cause of medical reform.

Dr. Major Greenwood leaves by his first wife a son, Captain M. Greenwood, R.A.M.C., of the Lister Institute of Preventive Medicine. In 1906 he remarried, and his widow survives him. To her and to Captain Greenwood we address our sympathies.

THE SERVICES.

ROYAL ARMY MEDICAL CORPS.

Capt. (temp. Major) J. Owen relinquishes his temporary rank.

Major William C. Croly to be acting Lieutenant-Colonel whilst in command of a Field Ambulance.

Capt. C. Woollard, C.A.M.C., to be temporary Major.

Temp.-Lieut. W. F. Gibb to be temporary Captain.

Temporary Honorary Lieutenants to be temporary Honorary Captains while serving with the Welsh Hospital, Netley: E. V. Jones and J. Boyd.

Officers relinquishing their commissions:—Temporary Captains: A. D. Forbes, R. V. Dolbey, J. I. M. Jamieson, and L. J. J. Nye, and J. H. P. B. Barrett, on account of ill-health. Lieutenants: E. C. Smith, F. H. Hurlburt, G. T. Griffith, A. J. Shilstra.

Lieutenants to be Captains: D. Loughlin, L. J. F. Bull, M. St. C. Hamilton, H. M. Wharry, J. P. Bracken, P. R. E. Kirby, E. H. V. Hensley, C. E. Bond, R. C. Davenport, R. H. Yolland.

To be Lieutenants: A. Rose-Innes, J. P. Williams, E. V. Beale, C. K. Mowll, D. Cameron, H. N. Pritchett, R. S. Corbett, H. W. H. Holmes, from University of London Contingent, O.T.C.; W. J. Walters; J. M. Norman, from Edinburgh University Contingent, O.T.C.; A. L. Packham; G. R. Hubbard; C. G. S. Milne from Aberdeen University Contingent, O.T.C.; S. Vidot; T. P. Chapman from Dublin University Contingent, O.T.C.; E. D. Roberts; W. J. Walters.

Second Lieut. A. Robertson, from Unattached List, T.F., to be Lieutenant.

Captains relinquishing their commissions: A. W. B. Loudon, A. Ramsbotham, W. F. Munro, W. H. P. Hey, K. W. Jones, D.S.O.

TERRITORIAL FORCE.

Lieut.-Col. (temp. Col.) W. K. Clayton relinquishes his temporary rank on vacating the appointment of Assistant Director of Medical Services, and is restored to the establishment.

Lieut.-Col. (temp. Col.) R. Pickard, C.M.G., relinquishes his temporary rank on vacating the appointment of Assistant Director of Medical Services, and is restored to the establishment.

Capt. (acting Lieut.-Col.) J. W. Mackenzie relinquishes his acting rank on alteration in posting due to reorganisation.

Major (acting Lieut.-Col.) F. B. Treves relinquishes his acting rank on alteration in posting due to reorganisation.

Capt. (acting Lieut.-Col.) R. Waterhouse to relinquish his acting rank on alteration in posting due to reorganisation.

Capt. (temp. Major) L. M. V. Mitchell relinquishes his temporary rank on alteration in posting due to reorganisation.

Capt. (acting Lieut.-Col.) H. N. Barnett relinquishes his acting rank on ceasing to command a Field Ambulance.

Capt. R. A. Broderick to be acting Lieutenant-Colonel whilst commanding a Field Ambulance.

Capt. (temp. Lieut.-Col.) E. Alderson reverts to the temporary rank of Major on ceasing to command a Field Ambulance.

Major (temp. Lieut.-Col.) W. M. Sturrock relinquishes his temporary rank on alteration in posting.

Majors to be temporary Lieutenant-Colonels: H. B. Roderick, A. Cooke, F. W. Burton-Fanning.

Captains to be temporary Majors: W. Tyson, H. A. Cookson, M. G. Foster, J. H. Thursfield, H. W. Wilson, F. D. S. Jackson, W. S. Colman, E. R. Carling, G. A. Ewart, J. Everidge, D. H. de Souza, A. J. Jex-Blake.

Major F. J. Steward to be temporary Lieutenant-Colonel.

Lieut.-Col. Sir J. K. Fowler, K.C.V.O., is restored to the establishment.

Major G. N. Biggs to be temporary Lieutenant-Colonel.

Major J. G. Martin to be acting Lieutenant-Colonel whilst commanding a Casualty Clearing Station.

Capt. P. G. Williamson to be Major.

Capt. C. Mearns to be Captain.

Captains restored to the establishment: A. Ramsbottom, W. F. Munro, A. W. B. Loudon, K. W. Jones.

Capt. R. E. Bickerton, D.S.O., to be acting Lieutenant-Colonel whilst commanding a Field Ambulance.

Major (temp. Lt.-Col.) J. C. S. Burkitt relinquishes his temporary rank on alteration in posting.

Major (temp. Lt.-Col.) W. S. Kerr relinquishes his temporary rank on ceasing to command a Field Ambulance.

Capt. (acting Lt.-Col.) F. D. Blandy relinquishes his acting rank on ceasing to command a Field Ambulance.

Capt. (temp. Maj.) W. Blackwood to be acting Lieutenant-Colonel whilst commanding a Field Ambulance.

Capt. W. H. P. Hey is seconded for service overseas.

To be Lieutenant: J. Waterston.

Lieutenants to be Captains: W. J. Wilson, D. Lyon, R. E. Pitts.

Lieut.-Col. A. A. Watson relinquishes his commission.

Capt. F. Smith relinquishes his commission on account of ill-health.

Capt. S. Hughes relinquishes his commission on account of ill-health, and is granted the honorary rank of Captain.

Capt. H. G. Smeeth relinquishes his commission.

Correspondence.

"Audi alteram partem."

THE LATE SIR VICTOR HORSLEY.

To the Editor of THE LANCET.

SIR,—Last July came the news of Sir Victor Horsley's death in Mesopotamia. We ought to have some record of his life and of his work; we cannot afford to forget him and what he did for medicine and surgery. I am collecting notes for a book; I hope that it will plainly show what we lost when we lost him. I ask for help in this venture from his friends and colleagues, and from the many patients in hospital practice or in private practice who have reason to be thankful for his skill and his kindness. I want all that they can tell me of him, and any letters of his which they will let me use. Without their help nothing that I can write of him will be of much service to anybody. Great care will be taken to return all letters.—I am, Sir, yours faithfully,

21, Ladbroke-square, W.11, May 24th, 1917. STEPHEN PAGET.

THE LUMLEIAN LECTURES AND MEDICAL RESEARCH.

To the Editor of THE LANCET.

SIR,—It has necessarily been a terrible shock to me to receive such a snub from Sir James Mackenzie in your last issue. When Olympian Zeus frowns the world must needs tremble. And what of the unfortunate individual? I, however, console myself to this extent, that the majority of those who are interested in the progress of heart disease are aware that from 1900–13 no year has gone by in which my collaborators and I have not endeavoured to throw some new light on the problems of rheumatism and heart disease. In passing, I would correct his statement that the microbe was "my discovery." First described in 1899 by Wassermann, it was worked out in the various lesions and demonstrated by Dr. Paine and myself in 1900. This work took two years and was overlapped by Wassermann, who got home first on rheumatic arthritis.

That the discovery has been therapeutically and clinically sterile is in its turn a discovery—Sir James Mackenzie's discovery. It is hardly, I think, yet corroborated by the numerous clinical assistants who have kindly worked with me, or by the hundreds of rheumatic children and many adults I have supervised in the last 18 years. Such corroboration, however, necessarily takes time. I regard it as a kindly act on his part to indicate how I should have worked and be working at the subject instead of bawling "my discovery." Yet I am embarrassed to this extent that already (1900–1905) I had shown with Dr. Paine that an important site of entrance of the infection, long suspected, was the tonsillar region, and that already in my writings on heart disease and rheumatism in children I have described the earliest stages and their clinical importance. I should have done more I admit, but the routine of a general physician is arduous. For at least ten years steady preventive work has been done on the throat and nose both at University College Hospital and the Hospital for Sick Children, and I should have hoped, nay even expected, that it would have reached Sir James Mackenzie by A.D. 1917.

I would assure him I am not at all at a loss as to what to do with "my discovery." I am aiming at the prevention of rheumatic heart disease in childhood, and need the assistance of our profession. This is a long affair, not so rapid, for example, as a polygraph tracing. I am aiming at the arrest of the advance of heart disease in childhood by, among other steps, the institution of special rest-homes. I am trying to take my part in persuading our profession that salicylate of soda is not a specific remedy. Lastly, I am trying to introduce a modern study of heart disease based upon the development of infective heart disease in childhood. The study of heart disease in general terms is at present upside down, and I want to put it the other way up. When I have succeeded, which will not be at once, heart affections will be placed in their correct perspective in human ailments—a decided advance, I think, if we may judge by many of the recent writings. The peculiarities of adult cardiac disease will then also be recognised in the process of evolution. I have other aims, but those enumerated will probably suffice to occupy the rest of my life-time.

I am, Sir, yours faithfully,

Devonshire-place, W., May 26th, 1917. F. JOHN POYNTON.

TUBERCULOSIS AND THE WAR.

To the Editor of THE LANCET.

SIR,—At one time I was probably as enthusiastic for sanatorium treatment as Dr. E. E. Prest[1]; in fact, when in Parliament, and later, I had a good deal to do with the agitation which resulted in the erecting of a sanatorium of 370 beds in Western Australia. When in charge of the Coolgardie Sanatorium, however, I found that some patients treated in their own homes did better than any similar cases treated in the sanatorium. When I came to England to study the problem of the relation of dispensary to sanatorium treatment for tuberculosis, I was fortunate in being appointed to my present position for the duration of the war, which has a large dispensary as well as a small sanatorium of 27 beds. This has given me the opportunity I sought. The conclusion to which I have come after two years of study of that phase of the question is that, although for a certain number of tuberculous patients sanatorium treatment is not only beneficial but essential, in the majority of the really early cases a sanatorium is not only not necessary but inadvisable.

Dr. Prest and I would probably differ in our definition of an "early case." I would probably consider his "early case" further advanced as we both appear to differ as to the meaning of "cured." What he would consider cured I would consider as arrested. To me an early case is one which used to be considered as incipient phthisis—that in which the individual's resistance to the tuberculous invasion is threatened. In the same way the so-called cured cases are, to me, cases in which resistance has been re-established. The fact, however, remains that in a large number of cases the resistance can be re-established without sanatorium treatment, and this especially holds of the working class, where it will be frequently discovered that the cause of loss of resistance is working overtime or undue strain of some kind which can be relieved, though in a number of these cases it cannot be done except in a sanatorium. It is the insistence on the need for sanatorium treatment in all cases that does so much mischief and makes many people hesitate, when they suspect tuberculosis, to have their suspicion verified.

This year and last we had 104 cases working, earning full wages and attending the dispensary, and of these only four have died from any cause, and only three have had to be taken from work and are going downhill. I have about 60 cases a month sent to me for diagnosis, of whom about half show definite evidence of what may be considered active tuberculosis, and there are some 800 cases under observation. Our funds and opportunities allow about ten beds in the sanatorium each month. With proper supervision this is sufficient for the treatment of all cases in Class 1.

The great problem that at present needs serious consideration and discussion is not "how to send all cases to a sanatorium," but "When is sanatorium treatment necessary and beneficial, and how many beds are necessary for those cases who can by that means have their resistance raised?" This is essentially a question for the dispensary to solve, where all classes of cases are seen during their whole time, not one or two classes for part of their time.

The present interest in the matter gives hope for a future settlement of this question of national importance, and its foundation must rest on the information acquired in a tuberculosis dispensary and the administration of the National Insurance Act. I am, Sir, yours faithfully,

HENRY A. ELLIS.

Tuberculosis Dispensary, Middlesbrough, May 21st, 1917.

THE TECHNIQUE OF LUMBAR PUNCTURE.

To the Editor of THE LANCET.

SIR,—In reference to the correspondence on the subject of what Dr. T. J. Horder aptly terms a restricted flow from a tense theca I should like to add a few observations from my personal experience gained from 1100 punctures performed on cases of real or suspected meningitis.

[1] See THE LANCET, May 5th, 1917, p. 700.

In the first place a restricted flow may occur drop by drop, simulating the normal rate, or, on the other hand, five or six drops may run in rapid succession, followed by a pause. This latter phenomenon would at once suggest that the mouth of the cannula was not lying free in the arachnoid space. Another point is that when such a restricted flow occurs the respiratory movements are not imparted to the column of fluid. The explanation of this occurrence must of necessity be largely a matter of conjecture. A possible explanation is furnished by the surmise that the dura mater is pushed in front of the needle and then pierced, the mouth of the cannula thus lying in a narrow chink between the approximated dorsal and ventral dura mater. The dura mater is bound to the bony canal by loose areolar tissue which could be easily separated by a comparatively blunt needle. In this regard I may remark that this contretemps occurs most frequently when the needle fails to reach the theca at the first plunge and has already struck bone. Further, I have more often met with this difficulty at the end of a series of eight or ten operations on different patients when the same needles had to be reboiled and used a second time. The simple manœuvre of gently withdrawing the needle will frequently establish a good flow, possibly by widening the interval between the surfaces of dura mater. Rotation of the needle will in some instances establish a full flow, particularly if the needle has been introduced in such a way that the mouth of the cannula does not look directly towards the cephalic aspect of the arachnoid space. If these manœuvres fail a full flow will always be obtained by taking a sharp needle and selecting another space. A "dry puncture," except in cases of hydrocephalus, I take to be proof-positive that the needle has not entered the theca. Where the fluid is thick and purulent and a good flow cannot be obtained even with the assiduous use of the stylet it seems probable that, as Dr. Horder suggests, the needle may have entered a loculus. A fresh puncture at another level will often secure a more abundant flow. When the fluid is blood-tinged and not obviously purulent it is better to perform a fresh puncture in order to obtain fluid free from blood for cytological examination. I have rarely found fluid blood-stained on a second puncture at another level.

I am, Sir, yours faithfully,

MICHAEL FOSTER,

British Expeditionary Force, May 22nd, 1917. Captain, R.A.M.C. (T.).

TRENCH SHIN.

To the Editor of THE LANCET.

SIR,—While greatly interested in Lieutenant-Colonel Graham Chambers's paper on "Trench Shin" in your issue of May 19th, experience does not lead one to agree with all he has to say regarding etiology and treatment. Opportunities for observing this complaint have been incessant during two and a half years' work with a battalion on the Western front, though there has been no chance of following up the more severe cases. If the disease is micro-organic in origin and possibly infective, which seems probable, constriction and exposure must play a very minor part. Last winter this battalion suffered more from exposure and deep mud than even in 1914, yet more cases are occurring now when the weather is good and the recent fighting has been more or less in open and clean country. Experiences in 1915 and 1916 bear this out. If the puttee played an important part as a causative factor, one would expect far more cases in the infantry, and the incidence of the disease (like the wearing of the puttee) to be continuous. The name "infectious fibrositis" precludes constriction and exposure. Those who previously held that trench foot was due to the tight puttee, and others who now hold it to be an infection with *Scopulariopsis koningii* from contact with mud, will both doubtless find analogical comfort in this paper on "Trench Shin."

With regard to experimental treatment, in slight cases, one's energies are naturally limited by the medical pannier. The pain is most intractable; to relieve it and so give sleep, aspirin, phenacetin, and sodium salicylate quite fail in small or large doses; opium has disadvantages; in fact, morphia injections alone are reliable, and they of course cannot be repeated indefinitely. The pain is greatly increased by constriction and bandaging; lessened by gentle massage and the use of liniments. Complete rest, unless the pyrexia is marked, does not seem so desirable as "light duty," because the pain is at its worst when resting. Elevation of the legs is indicated. The disease seems self-limiting, and tonics and rest usually restore the health in from 10 to 30 days. After careful inquiry and observation, the much suspected and often guilty louse has been let off with a caution as being the cause of "trench shin"; for the worst cases have often occurred among the cleanest N.C.O.'s and men. On the other hand, officers in this battalion—usually free from lice—have never been sufferers.

I hope Lieutenant-Colonel Graham Chambers will take this not so much in the light of a criticism of his paper as a statement of the experiences of the writer.

I am, Sir, yours faithfully,

IVAN C. MACLEAN,

B.E.F., France, May 26th, 1917. Temporary Captain, R.A.M.C.

THE PARAFFIN TREATMENT OF BURNS.

To the Editor of THE LANCET.

SIR,—As chief surgeon of a Russian flying surgical column for two years, and of one of the largest Russian field hospitals for the past seven months, I have had the handling of a good many cases of burns, frost-bites, and scalds, and was at my wits' end, so to speak, for a treatment that would relieve pain, promote healing, and at the same time act as a disinfectant. About a year ago I heard about the paraffin treatment used in France. Unfortunately, it was practically impossible to obtain any of this remedy. I have, however, been using for nearly a year the following formula:—

Resin, 1 part; beeswax, 1 part; paraffin, 4 parts. Melt in a dish set in boiling water for half an hour. I put it on the same way as the French remedy is used. With a metal spray, spray on a thin coat, then cover with a very thin layer of cotton. Then with a camel's-hair brush put on three or four layers of the wax. After it has hardened for 10 minutes bandage.

Frozen toes, fingers, and ears respond splendidly. In scalds (we have many on account of the Russian steam baths) the pain is entirely stopped at once, and the skin heals readily. Burns from the German liquid fire are often very deep, the pain and suffering is intense, yet after applying the wax the patients soon go to sleep. Care must be taken not to let any water get into the wax. Only a small patch should be sprayed at a time, and covered with a thin layer of cotton while the wax is still hot. Another area should then be sprayed until the whole wounded surface is covered. Finally, with long strokes of the brush, redipping with each stroke, the whole area is gone over again. A new covering is put on each day until there is no further sign of pus, then every two or three days. I am, Sir, yours faithfully,

EUGENE HURD,

Russian Front, April 9th, 1917. Surgeon-Colonel.

THE INSTITUTE OF MASSAGE AND REMEDIAL GYMNASTICS.

To the Editor of THE LANCET.

SIR,—In the April number of the *Journal of the Incorporated Society of Trained Masseuses* an account was given of the formation, of the Institute of Massage and Remedial Gymnastics and a more or less accurate description of the negotiations which took place up to the conference between delegates of the advisory board and of the council of the Incorporated Society of Trained Masseuses on the one side and of the Institute of Massage and Remedial Gymnastics on the other side. The article ends with the following paragraph:—

> The representatives of the newly formed Manchester Institute who attended the conference mainly directed their remarks to criticising the methods and constitution of the Incorporated Society of Trained Masseuses, and the conference broke up without any tangible result being attained.

In the notes of the conference made by the advisory board of the Incorporated Society of Trained Masseuses the following paragraph occurs:—

> It was decided that no shorthand writer should be present at the conference, and that the proceedings should be regarded as confidential, though no objection was taken to either party communicating the general tenor of the discussion to their respective councils.

The article referred to is, therefore, a breach of the agreement which was entered into at the conference. As negotiations are still proceeding as a result of the conference, it is too early to say whether they will be successful or otherwise, but this article is so prejudicial to the interest of the profession of massage for which we are working, that we feel it is essential to express our disapprobation of the course adopted without further delay.

We are, Sir, yours faithfully,

W. MILLIGAN, M.D., Chairman of the Executive Council

A. E. BARCLAY, M.D., Honorary Secretary.

71, King-street, Manchester, May 26th, 1917.

The War.

THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue :—

Killed.

Capt. W. G. Cummings, R.A.M.C., received his education at Queen's University, Belfast, and qualified in 1903. He was in practice at Hanwell, London, at the outbreak of war and joined the R.A.M.C. forthwith. He was a first-class Rugby player in his student days.

Lieut.-Col. W. B. Grandage, Royal Field Artillery, was engaged in the war as a combatant officer. He was educated at Cambridge and at St. Bartholomew's Hospital, qualifying in 1905, and held appointments at the Victoria Hospital for Children, at the Queen Charlotte Lying-in Hospital, and at St. Bartholomew's. He was a well-known Rugby football player and was engaged in practice in South Kensington prior to the war.

Drowned.

Capt. H. H. Robinson, D.S.O., R.A.M.C., was educated at Owens College, Manchester, and qualified in 1899. Before joining the R.A.M.C. he was in practice at Birkenhead, where he was honorary medical officer to the Children's Hospital. He was awarded the D.S.O. in August last year (see THE LANCET, Sept. 2nd, 1916, p. 450).

Died.

Captain R. F. Russell, R.A.M.C., qualified in 1905 at Aberdeen and practised at Methlick, Aberdeenshire, where he was medical officer and public vaccinator, and later joined the Jamaica Medical Service.

Missing, believed Drowned.

Capt. C. A. W. Pope, R.A.M.C., was educated at Cambridge and at St. Bartholomew's Hospital, London, and qualified in 1903. He had held appointments at the Somerset Hospital, Capetown, and at the South Devon and East Cornwall Hospital, and had been medical officer in charge of military families at Aldershot. He was in practice at St. Leonard's-on-Sea prior to joining the R.A.M.C.

Lieut. J. G. B. Smith, R.A.M.C., was a student at St. Bartholomew's Hospital and qualified in 1915.

Capt. A. Tilbury, R.A.M.C., was a student at Guy's Hospital and qualified in 1913. He was in practice in South London when war broke out and was given a commission in the R.A.M.C. He saw service in Egypt and returned to England later. He went down in the torpedoed s.s. *Transylvania*.

Previously reported Missing, now reported Killed.

Surgeon A. M. Russell, R.N., qualified at Glasgow in 1914, and joined the Navy soon afterwards.

Previously reported Wounded, now reported Died of Wounds.

Capt. R. H. Wilson, R.A.M.C., attached R.F.A., qualified at Belfast in 1915, and joined up soon afterwards.

Wounded.

Lieut. A. S. Carter, R.A.M.C., attached Worcester Regt.
Capt. J. C. Fergusson, R.A.M.C.
Lieut. J. W. Mackie, R.A.M.C., attached Northumberland Fusiliers.
Capt. H. N. Stafford, R.A.M.C.
Capt. J. F. Bourke, M.C., R.A.M.C., attached Scottish Rifles.
Capt. T. J. Gilmore, R.A.M.C., attached Gloucester Regt.
Capt. J. A. Gilfillan, R.A.M.C., attached Seaforths.
Lieut.-Col. J. J. Fraser, Canadian A.M.C.
Capt. W. W. J. Lawson, R.A.M.C.

DEATHS AMONG THE SONS OF MEDICAL MEN.

The following sons of medical men must be added to our lists of those who have fallen during the war:—

Acting Capt. C. C. Codner, Somerset Light Infantry, younger son of Dr. J. Codner, of Corfe, near Taunton.
Lieut. B. O. Warner, Essex Regiment, youngest son of the late Dr. P. Warner, of Woodford Green, Essex.
Second Lieut. J. M. Dunwoody, Royal Dublin Fusiliers, only son of Dr. W. G. Dunwoody, of Ramsgate.

[The name of Capt. C. A. R. Gatley, R.A.M.C., should not have been included under this heading in our last issue, and we much regret the error. Capt. Gatley is wounded, and is at present in the Hall Walker Hospital for Officers at Regent's Park, London.]

THE HONOURS LIST.

The following awards to medical officers are announced :—

Bar to the Military Cross.

Temp. Capt. Reginald Peter Nutcombe Buckland Bluett, M.C., R.A.M.C., attached Highland Light Infantry.

For conspicuous gallantry and devotion to duty. He displayed great judgment and endurance in organising the stretcher-bearers in the attack. He worked continuously throughout the day, exposed for many hours to very heavy hostile fire.

(The award of the Military Cross was announced in THE LANCET of April 8th, 1916, p. 798.)

Military Cross.

Temp. Capt. Thomas Dowzer, R.A.M.C., attached Manchester Regiment.

For conspicuous gallantry and devotion to duty. He showed great personal bravery in moving about in the open under heavy fire, organising his bearers, and assisting in the search for the wounded.

Capt. Thomas Graham, R.A.M.C.

For conspicuous gallantry and devotion to duty. He rendered invaluable assistance in evacuating the wounded under very heavy fire. He has at all times set a splendid example of courage and determination.

Capt. Thomas Whittle Martin, R.A.M.C., Spec. Res., attached Royal Scots.

For conspicuous gallantry and devotion to duty. He was of the greatest assistance in organising the evacuation of the wounded across "No Man's Land" during the operation. He has on many previous occasions done fine work.

Temp. Capt. Francis Lorne McKinnon, R.A.M.C.

For conspicuous gallantry and devotion to duty. He personally led a search party up to the enemy wire in front of the village, under very close rifle and machine-gun fire. He succeeded in recovering two wounded men.

Temp. Capt. Charles O'Brien, R.A.M.C.

For conspicuous gallantry and devotion to duty. Although wounded, he insisted on remaining in command of the bearer division of his field ambulance, and in so doing materially expedited the removal of the wounded from the field.

Capt. Bertrand Cecil Owens Sheridan, R.A.M.C., Spec. Res., attached Worcester Regiment.

For conspicuous gallantry and devotion to duty. He tended the wounded continuously for 12 hours under very heavy fire. He set a splendid example of courage and determination throughout.

Capt. George Charles Willcocks, Australian A.M.C.

For conspicuous gallantry and devotion to duty. He worked continuously for about 16 hours in the open under heavy fire and successfully evacuated a large number of wounded men. He set a splendid example of courage and determination.

MENTIONED IN DESPATCHES.

In a despatch dated April 9th, 1917, received from Field-Marshal Sir Douglas Haig, G.C.B., Commander-in-Chief of the British Armies in France, the names of the following medical officers are mentioned:—

Royal Navy.—Temp. Surg. H. B. Padwick, D.S.O.
Royal Marines.—Temp. Surg. J. N. M. Ross, R.N.

Army Medical Service.

Headquarters Staff.

Lt.-Col. (temp. Col.) J. D. Alexander, R.A.M.C.
Capt. D. C. G. Ballingall, M.C., R.A.M.C.; Lt.-Col. (temp. Col.) H. P. W. Barrow, C.M.G., R.A.M.C.; Capt. J. J. H. Beckton, R.A.M.C.; Lt.-Col. (temp. Col.) W. C. Beevor, C.B., C.M.G., ret. pay; Lt.-Col. W. W. O. Beveridge, C.B., D.S.O.; Col. A. W. Bewley; Lt.-Col. (temp. Col.) R. J. Blackham, C.I.E., D.S.O., R.A.M.C.; Lt.-Col. W. R. Blackwell; Lt.-Col. (temp. Col.) B. W. Bliss, D.S.O., R.A.M.C.; Lt.-Col. (temp. Col.) A. W. N. Bowen, R.A.M.C.; Lt.-Col. (temp. Col.) G. W. Brazier-Creagh, C.M.G., ret. pay; Col. E. G. Browne, C.B.; Col. C. H. Burtchaell, C.M.G.
Col. H. Carr, C.B.; Capt. F. Casement, R.A.M.C.; Maj. H. St. M. Carter, D.S.O.; Lt.-Col. S. L. Cummins, C.M.G.
Capt. K. K. Drury, M.C.
Lt.-Col. and Bt.-Col. H. Ensor, D.S.O., R.A.M.C.
Lt.-Col. H. B. Fawcus, C.M.G.; Temp. Col. C. C. Fleming, D.S.O., ret. pay (Res. of Off.).
Col. J. J. Gerrard; Capt. A. J. Gibson; Lt.-Col. (actg. Col.) J. G. Gill, R.A.M.C.; Lt.-Col. (temp. Col.) J. Grech, D.S.O., R.A.M.C.; Lt.-Col. (temp. Col.) F. J. Greig, ret. pay (Res. of Off.).
Maj. J. A. Hartigan, D.S.O.; Lt.-Col. (actg. Col.) H. Herrick, R.A.M.C.; Temp. Capt. G. J. D. Hindley, R.A.M.C.; Lt.-Col. (temp. Col.) H. A. Hinge, C.M.G., R.A.M.C.; Lt.-Col. (temp. Col.) A. W. Hooper, C.M.G., D.S.O., R.A.M.C.
Col. (temp. Surg.-Gen.) J. M. Irwin.
Col. R. Jackson.
Col. E. Kirkpatrick, C.M.G.

Silver Medal for Military Valour.—Capt. H. H. Burnham, Canadian A.M.C.; Temp. Capt. H. N. M. Puckle, R.A.M.C.; Temp. Capt. M. Scott, R.A.M.C.; Temp. Capt. C. McM. Wilson, M.C., R.A.M.C.

THE SUPPLY OF MEDICAL OFFICERS FOR THE ARMY: POSSIBLE AMERICAN ASSISTANCE.

The Central Medical War Committee has been working steadily and at great pressure to meet the demands of the War Office for medical officers for the Army, and the position indicated in these columns some time ago as imminent has clearly been reached. In existing circumstances all the War Office demands cannot be met. The information that a large number of American medical men will shortly be available for service in France has been considered by many to promise an amelioration of the situation, but there is as yet no definite and official warrant for believing that the problem of an adequate supply of medical officers for the British Army will be solved in this way. Undoubtedly there are American medical men promptly available to serve for the time being with our Army or with the French Army, and probably more of the same gallant assistance will be forthcoming. Recognition of the qualifications of these American confrères by their Medical Association or statutory Colleges would enable them to be at once available for the armies at the Allied fronts. But these American doctors would probably have to be returned to the American Army when expeditionary forces begin to arrive from the United States. A temporary respite from acute trouble, however, might be gained through the employment of American doctors, and such respite would be valuable to this country where the supply of medical men has become so dangerously short. The subject is now under the discussion of the Central Medical War Committee. No one who is aware of the circumstances in which exemption is refused or obtained by our medical men of military condition can possibly suggest that the Central Medical War Committee takes other than a very high view of its responsibilities towards the Army. It has, however, an enormously important duty towards the civilian population in this country, and cannot be blind to it. So closely have the areas in England been scrutinised with a view to obtaining every medical officer for the Army, so intensive is the method of investigation and reinvestigation now being conducted, that it seems certain that should all this energy and self-sacrifice not bear sufficient fruit the Army will have to economise in the employment of medical men under some plan of redistribution or reorganisation. There are already men being sent into the Army who can badly be spared by the State.

HAMPSTEAD MEDICAL WAR COMMITTEE.

Having regard to the fact that medical men who have relinquished their commissions in the Army are now returning to practise, the following resolution was recently passed by the Committee:—

This Committee is of opinion that there should be no receding from the terms of the undertakings issued by this or other Medical War Committees. No request from returning doctors should absolve the members of the profession from their obligations incurred by the undertakings.

The resolution was occasioned on account of the apparent disloyalty of some members of the public towards the men who have sacrificed so much by accepting commissions, although over military age. If the members of the profession are loyal to their undertakings it is hoped that the laity will learn from them.

The undertaking referred to is one which was almost universally signed and agreed to in November, 1915, and will be remembered by all our readers.

AN IMPERIAL MEDICAL AND NURSING SCHEME.

Sir J. Kingston Fowler, late consulting physician to the Army in France, has issued through Messrs. Macmillan and Co., in the form of a pamphlet, a scheme for the organisation of the medical and nursing professions of the Empire for war, in the hope that it may serve to stimulate imagination and thought and foster *esprit de corps*. Beginning with a tribute of praise to the splendid work of the Royal Army Medical Corps, both Regular and Territorial, during the war, and to the foresight and ability of Sir Alfred Keogh, K.C.B., who organised the medical services of the Territorial Force, thus enabling the country to provide fully equipped hospitals ready to receive patients before the wounded arrived from France, he says, "this should not lead us to think that perfection has been attained ..... and every effort should be made to ensure that the experience now in many minds is not lost after the war is over, but is utilised for our future advantage." After describing the medical service of the old Volunteer Force, which had many defects, and the existing system under the Territorial Force, he outlines the proposed scheme which is to utilise the sentiment of attachment to the medical schools as a factor in the organisation of the medical profession for war.

Any scheme of the kind must fulfil certain conditions: It must be independent of the form of military service, whether voluntary or compulsory, or territorial; it must be flexible and capable of unlimited expansion; it should be applicable to the whole Empire; it must recognise that allegiance to an Alma Mater may by long association with another institution be transferred; it must provide for men who have no such allegiance; it must have regard to those universities which only make provision for the preliminary and intermediate subjects of a medical education; it must recognise that in the Scotch universities the number of graduates is so large that the sentimental attachment is, as regards some of them, possibly weaker than obtains in the London schools; provision must be made for the inclusion of general hospitals situated in large towns in which there is no medical school, as in regard to these hospitals there is a strong feeling of attachment amongst the medical men of the town and county; the names given to the hospital units must be reminiscent of their origin and of Home. While it is true that the mention of a number may be a powerful aid to the imagination, as witness the numbers of many regiments, in relation to hospital units numbers are weak. The regiment never dies; its traditions are quickly learned by the recruit, but the hospital units are formed *ad hoc*, and after a war is over they disappear, and any *esprit de corps* that may have been evoked is lost and forgotten.

The proposal is to name the hospitals after the school, college, university, or town from which the personnel has been drawn, and which in each case forms the bond uniting the individual members of the staff to one another. For example, such names as No. 1 London General Hospital, R.A.M.C. (T.), No. 1 Northern General Hospital, R.A.M.C. (T.), and all the others so named would disappear from the Army List and would be replaced by No. 1 Oxford University, No. 1 Cambridge University, No. 1 Edinburgh University, No. 1 St. Bartholomew's Hospital. The permanent staff of a centre would consist of the commanding officer, the adjutant, the quartermaster, and a certain number of orderlies. The duties of the commanding officer and adjutant in time of peace would be—

To receive all communications from the War Office and to carry the regulations into effect; to keep the mobilisation roll; to receive applications for admission to the roll, and to accept or refuse them; to classify the applicants according to their attainments and record of work; to recommend officers for commissions in the units under their control; to keep up the personnel of at least one complete general hospital, and usually of two or more such hospitals—of these No. 1 would be for service in this country; No. 2 possibly for service abroad;—to carry out the regulations as to the training of the orderlies; to receive the order "Mobilise," and to carry it into effect; in time of war to maintain the personnel of their units and to provide drafts for the units of the fighting line as required by the War Office. The number of names on any roll would necessarily be far greater than would be required to maintain the personnel of the units for which the centre was responsible.

The personnel of No. 1 Hospital of any centre would consist of seniors—i.e., physicians, surgeons, officers in charge of special departments—who would serve in the military hospital at home. No officers liable for general service abroad in time of war should be appointed to No. 1 Hospital of any centre. The staff of No. 2 would consist of younger members of the honorary staff, with a similar complete personnel necessary for a general hospital abroad. Similarly with No. 3, and so on. Each hospital, whether serving abroad or at home, should be provided with a fully equipped bacteriological laboratory which is essential in the interest of the patients. Probably in many cases the institution or town responsible for the units would provide, as a gift, the laboratory and X ray outfit.

Among the advantages claimed for the scheme are its applicability to the whole Empire and its elasticity. The organisation of the nursing profession would follow broadly on the lines already suggested for the medical profession.

THE TREATMENT OF THE WAR CRIPPLE.

The statement by the Minister of Pensions, on which we commented last week, has now been supplemented by a very welcome circular addressed by the President of the Local Government Board to boards of guardians in regard to discharged disabled soldiers and sailors detained in Poor-law institutions. Under the terms of the new Royal Warrant any disabled man who is in receipt of a pension and has been recommended for special treatment in a sanatorium or other institution is entitled to an allowance of not less than 27*s.* 6*d.* a week for himself and an appropriate allowance for his wife and children, the local War Pensions Committees being charged with the duty of making the requisite arrangements for the institutional treatment of men residing within their area. In view of these provisions, the circular states, no discharged disabled man should in future be under the necessity of seeking Poor-law relief in a workhouse or infirmary in any case where the incapacity from which he is suffering is due to his disablement. The guardians are asked to communicate with the local War Pensions Committee of their area in regard to any such cases at present in institutions under their control. Future applications from discharged men should be referred at once to the local War Pensions Committee. The proposed surrender of the functions of the Statutory Pensions Committee to the Ministry of Pensions should serve still further to unify procedure.

THE UNITED STATES AND MEDICAL ORGANISATION FOR THE WAR.

The Sanitary Service in the Field.—In the field, according to the *Journal of the American Medical Association*, the sanitary service of the United States Army is divided into two sections—for the zone of advance and the line of communications. In the first zone the mobile sanitary units are located, the second being specially concerned with supply and the evacuation of sick and wounded. The general arrangements are similar to those in the large European armies. With each division there are four ambulance companies under a director, each company consisting of 5 medical officers and 79 enlisted men, with 12 ambulances and 3 wagons for the transport of supplies. On going into action immediate first-aid is performed by the sanitary detachments belonging to each regiment. Dressing stations are established at various parts of the field as required on the notification of the divisional surgeon, from which the wounded are removed to field hospitals in the rear. Four field hospital units are attached to a division under the control of a director of field hospitals, each to accommodate 216 patients, and with a personnel of six medical officers and 67 enlisted men. Where existing buildings are not available tents are to be erected. The field hospitals themselves can be evacuated as quickly as possible and the wounded removed to hospitals further in the rear. It is here that the Red Cross organisation comes into play. A motor transport is now being organised. The medical service on the lines of communication, which may nowadays be anything from 50 to 300 miles, is in charge of a surgeon stationed at the base, with a second to supervise the evacuation of the wounded from the time of leaving the field hospital until reaching the hospital train for the base. To prevent congestion on the railways bringing up supplies, two evacuation hospitals at the head of the line of communication are allotted to each division, each with a personnel of 14 officers and 153 enlisted men. These hospitals have a normal capacity of 432 beds, with sufficient supplies on hand to provide for sudden expansion. In the same hospitals complete treatment is provided for those who cannot be removed further owing to the serious nature of their wounds, and for those who will recover completely within a week or ten days. Evacuation from the line-head to base will eventually be carried out by fully-equipped hospital trains, providing the same care as a permanent hospital. Only one such train is at present ready for use. Base hospitals will have a capacity of 500 beds each with a personnel of 20 officers, 153 men, and 46 female nurses, but will be able to provide double accommodation at short notice. A convalescent camp is connected with each base hospital.

OBITUARY OF THE WAR.

FRANK ALBERT SYMONS, C.M.G., D.S.O., M.B. EDIN.,

TEMPORARY COLONEL, ROYAL ARMY MEDICAL CORPS.

Colonel F. A. Symons, who was killed on April 30th, was son of the late John Hughes Symons, of Nova Scotia, and received his medical education at Edinburgh University, qualifying M.B., C.M. in 1891. On the outbreak of the present war he was one of the first to leave England in command of a clearing hospital with the rank of lieutenant-colonel, and he had been abroad ever since. In November, 1915, he became temporary colonel and later Assistant Director of Medical Services. He was twice mentioned in Lord French's despatches, received the D.S.O. in the first honours list of the war, and was made a C.M.G. in the New Year honours list of the present year. He served in the South African War, where he was military secretary to the late Sir William Mac Cormac, with whom he was present at the battle of Colenso and the relief of Ladysmith.

"Colonel Symons was a splendid organiser and indefatigable worker," his Divisional General writes, "and these qualities, together with his cheery, tactful manner, won for him the affectionate regard of officers and men." Another writes of him as a valued senior medical officer, whose judgment in difficult situations was sound and practical.

Colonel Symons married in 1900 Dorothy, second daughter of the late Edmund Grove Bennett, of The Close, Salisbury, and leaves a widow and four children.

JAMES ELLIOT BLACK, M.B., CH.B. GLASG.,

MILITARY CROSS;
CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain J. E. Black, who was recently killed on active service in France, was the son of the late Adam Elliot Black, of Glasgow. He was educated at Cargillfield and Fettes College, graduating in medicine at Glasgow University in 1911. When war broke out he was studying for his D.P.H. Cambridge, but immediately volunteered for service, leaving in October, 1914, for France, where he was attached to a clearing hospital. He was one of the first medical officers to deal with drift-gas poisoning, and the results of observations on 685 such cases by himself and others were embodied in a paper published in the *British Medical Journal* of July 31st, 1915. In April, 1915, he was promoted to the rank of captain, and in January of the following year his name was mentioned in despatches. Later he became attached to the 8th Bedfordshire Regiment. His award of the Military Cross was recorded in THE LANCET of Nov. 18th last year for conspicuous gallantry and devotion to duty in the field. "He rendered valuable services when attending the wounded under heavy machine gun and shell fire. Later, he went out into 'No Man's Land' to succour the wounded." One of his fellow-workers in the pathological institute of the London Hospital, where he acted as assistant in 1912, writes: "An indefatigable worker in spite of poor health, gentle and kindly, always ready to help, modest to a degree which made him ignorant of his exceptional ability and of the value of his work, Captain Black had a personal charm which endeared him to all his colleagues."

ROBERT HOME, M.B., C.M. TOR.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain R. Home, who was recently reported killed on active service, was born in Toronto in 1890, graduating at his home University in 1913. Entering the Canadian Army Medical Corps, he served at the Military Hospital at the Exhibition Camp, Toronto, transferring to the Royal Army Medical Corps in November, 1915; at first with the 107th Field Ambulance, he was later medical officer of the 14th Gloucesters.

JOHN MARSHALL, M.B., CH.B. EDIN.,

LIEUTENANT, ROYAL ARMY MEDICAL CORPS.

Lieutenant J. Marshall, who was reported missing, believed drowned, on April 15th, was 30 years of age and eldest son of the late Alderman R. Marshall, J.P., of Berwick-on-Tweed. From Berwick Grammar School, where he was Johnston scholar and prizeman, he entered Edinburgh University, graduating M.B. Ch.B. in 1908 with first-class honours and the award of the McCosh travelling scholarship. After studying in Paris and Munich he was appointed house surgeon at Greenbank Hospital, Darlington, where he remained two years, leaving to become assistant to Dr. P. F. Mannix, of Lancaster. Latterly he had been resident at the Beaufort War Hospital, Bristol, until February of the present year, when he obtained a commission in the Royal Army Medical Corps. One of his intimates writes of him as a most unselfish man, respected and beloved by his patients, particularly by the poor.

GUY BROOKE BAILEY, M.B., B.S. MELB.,

CAPTAIN, AUSTRALIAN ARMY MEDICAL CORPS.

Captain G. B. Bailey, who was killed in the recent fighting in France, was 34 years of age at the time of his death and a medical graduate of Melbourne University. During his University career he took a prominent part in athletics, representing Trinity College in cricket and rowing. He was practising in Hobart, Tasmania, prior to joining the Australian Imperial Force. He leaves a widow and one child.

CLIVE BRITTEN BURDEN, M.B., CH.B. ADEL.,

CAPTAIN, AUSTRALIAN ARMY MEDICAL CORPS.

Captain C. B. Burden, who died on May 8th, aged 25 years, from injuries accidentally received, was the son of J. B. Burden, of Adelaide. He recently graduated in medicine at Adelaide University, where he was popular with his fellow students for his genial disposition and his skill in athletic sports. Joining the Australian Imperial Force in July last, he came over as a general reinforcement officer early in the present year, and later saw service in France. His loss is felt by brother officers here and by his many University friends in Australia.

ANOTHER HOSPITAL SHIP TORPEDOED.—On May 26th, at 6 P.M., the hospital ship *Dover Castle* was struck by a torpedo without warning in the Mediterranean and was sunk two hours later as the result of a second torpedo. All the patients and hospital staff were saved, as well as the whole crew with the exception of six men who were injured by the explosion.

GIFTS TO THE RED CROSS SOCIETY.—The Joint Finance Committee of the British Red Cross Society and the Order of St. John has received £5000, the result of an appeal made on behalf of the sick and wounded of the British armies by the Imperial Red Cross Committee of Newfoundland.

As a result of the Red Cross Sale held by Messrs. Christie in March and April last, £84,157 have been received by the British Red Society and the Order of St. John. The sale in 1915 produced £38,215, and that in 1916 £52,691.

WAR HOSPITAL MAGAZINES.—The May issues of the *Craigleith Hospital Chronicle* (Craigleith, Edinburgh, 6*d*.), the *Gazette of the 3rd London General Hospital* (Wandsworth, 4*d*.), and the *War Hospital Magazine* (Huddersfield, 3*d*.), maintain their standard, both in letterpress and illustration, making an appeal to the inmates and staffs of the hospitals they represent, as well as to the general public. The same may be said of the April issue of the *Ration* (Reading, 2*d*.). The profits on all these magazines are devoted to the provision of extra comforts for the hospital inmates, and we note with regret that, owing to the scarcity of paper, among other things, the *Craigleith Hospital Chronicle*, one of the earliest and best of this class of periodicals, will disappear as a monthly with the next issue. An occasional number may be issued from time to time.

A NAVAL FLEET-SURGEON'S IMPRESSIONS IN THE TRENCHES.—In order to strengthen the sympathetic bond between the sister services the Admiralty and War Office made arrangements in 1916 to send a certain number of naval officers to gain experience of trench life and a corresponding number of army officers to experience life afloat under war conditions. Fleet-Surgeon C. Marsh Beadnell, R.N., was one of the privileged officers of the Navy to visit the trenches, and the interesting account of his impressions, which was published in the January and April issues of the *Journal of the Royal Naval Medical Service*, has now been reprinted in the form of a pamphlet and published by Messrs. John Bale, Sons, and Danielsson, Great Titchfield-street, W. Naturally, the six days which the author spent in the trenches afforded only a glimpse of real trench life, but his observational powers enabled him to take in every detail which that glimpse afforded, and a useful as well as an interesting description with many humorous touches is the result. There is a description of the medical arrangements and an account of gas attacks, the routine to cope with this offensive, and the effects of the gas on man, animals, and vegetation. The itinerary includes a visit on foot to the firing trenches, a trip down the sap, and below No Man's Land.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates have passed in the subjects indicated:—

Surgery.—W. A. Bibby, Manchester; H. N. Dale-Richards (Sect. I.), St. Mary's Hospital; E. F. Deacon (Sect. I.), Guy's Hospital; J. Y. Dent (Sects. I. and II.), King's College Hospital; S. G. K. Kastelianski (Sect. II.), London Hospital; R. H. Pettersson (Sects. I. and II.), St. George's Hospital; G. W. Pratt (Sects. I. and II.), Cambridge; and F. A. Unwin (Sect. II.), Westminster Hospital.

Medicine.—E. A. Leak (Sect. I.), Cambridge and London Hospital; R. H. Pettersson (Sect. II.), St. George's Hospital; and L. J. Vincent (Sects. I. and II.), Cambridge and St. Mary's Hospital.

Forensic Medicine.—E. F. Deacon, Guy's Hospital; E. W. Diggett, Jefferson College, Philadelphia; L. E. Lewis, Glasgow; and D. Menzies, St. Mary's Hospital.

Midwifery.—G. S. Ashby, King's College Hospital; E. F. Deacon, Guy's Hospital; and M. Ibrahim, Middlesex Hospital.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—J. Y. Dent, S. G. K. Kastelianski, R. H. Pettersson, F. A. Unwin, and L. J. Vincent.

THE LATE MR. W. LE PAGE.—The death occurred on May 13th, at his residence in Guernsey, of William Le Page, L.R.C.P. Edin., L.F.P.S.Glasg., and L.M., aged 75, who was well known in the island. He was the son of Mr. Le Page and Amelia de Jersey and studied medicine at Durham University. He qualified by taking the triple qualification of Edinburgh and Glasgow. He had been a surgeon-lieutenant-colonel in the Royal Guernsey Militia, surgeon to St. Peter Port Hospital, surgeon to the Castel Hospital, and physician to the Castel Lunatic Asylum. He leaves a widow to mourn her loss.

LITERARY INTELLIGENCE.—Messrs. J. and A. Churchill announce the forthcoming appearance of a book entitled "Massage, its Principles and Practice," containing original photographic illustrations, by Dr. J. B. Mennell, physician to the Military Orthopædic Hospital, Shepherd's Bush, and one on "Surgical Nursing and After-treatment," containing over 100 illustrations, by Dr. H. C. R. Darling, assistant surgeon to South Sydney Hospital.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The annual meeting of this association will take place on July 25th, at 11, Chandos-street, Cavendish-square, London, W. The meeting, as in 1915 and 1916, will be held on one day only. In accordance with a by-law of the society, Dr. R. H. Steen, the acting honorary general secretary, requests the contribution of papers and other scientific matter. Dr. Steen may be addressed at the City of London Mental Hospital, Dartford, Kent.

THE annual general meeting of the Röntgen Society will be held on Tuesday, June 5th, at 8.15 P.M., at the Cancer Hospital (Free), Fulham-road, S.W. The adjourned discussion on the Future of the British X Ray Industry, will be opened by Captain R. Knox. Lieutenant-Colonel Robert Wilson, C.A.M.C., Mr. J. H. Webb, and Mr. Howard C. Head are expected to take part.

THE LATE MR. PETER MACEWAN, F.C.S.—We regret to learn the sudden death last week of Mr. Peter MacEwan, the editor of the *Chemist and Druggist*. His literary contributions to scientific pharmacy were numerous and valuable, and his knowledge of all the legal enactments dealing with his profession was intimate.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the committee, held on May 8th, 25 cases were considered, and £213 granted to 21 of the applicants. The following is a summary of some of the cases relieved:—

Wife, aged 56, of M.R.C.S. Eng. who practised at New Zealand and Hoxton. Applicant's husband has been paralysed for 28 years, and the little income he has is insufficient to support them. The wife prior to the war was able to earn as a teacher of music and languages, but cannot obtain pupils at present; and their only son, who used to help, has recently joined the Army and married. Voted £15 and referred to the Guild.—M.R.C.S. Eng., aged 74, married, who practised at Darlington and Malvern. Owing to ill-health and insufficient means, and the increased cost of living, unable to pay his way. His wife has recently broken her leg. Only income about £100 a year from son and friends. Rent £25. Voted £18 in 12 instalments.—Widow, aged 67, of M.R.C.S. Eng. who practised at Leighton Buzzard, and died in 1904. Applicant lost the small capital she had through fraudulent executors. Only income now 11*s*. per week provided by relatives. Pays 5*s*. 6*d*. per week rent; and high price of food makes it impossible for her to manage. Voted £12 in 12 instalments.—Widow, aged 46, of M.R.C.S. Eng. who practised at Brixton, and was an annuitant of the fund. Applicant left without means, and health very much impaired by the constant nursing, for the last eight years, of her husband, who was a chronic invalid. She hopes, after a rest, to find suitable employment, and then manage to earn a living. Voted £5. Widow, aged 58, of L.R.C.P. Edin. who practised at Blackburn, and died in 1902. Applicant was left unprovided for with a young daughter, now aged 19. Both have recently obtained work through the help of the Manchester branch of the Guild, and the prospects are brighter than they have been before, but they still require a little help to get their affairs straight, owing to their previous strenuous times. Relieved four times, £40. Voted £5.—Widow, aged 73, of M.R.C.S. Eng. who practised at Liverpool and died in 1887. Applicant kept house for her son, a medical man, who died in 1915 after a very strenuous time on war work. Applicant lives in own house, but it is heavily mortgaged. Takes in paying guests, but does not make sufficient to meet her liabilities. Relieved once, £10. Voted £10.—Widow, aged 41, of M.D. Glasg. who practised in London and died in 1910. Left entirely without means and has defective eyesight. In the summer months she earns 15*s*. a week as an attendant. In the winter months only has casual employment. Health has been very indifferent lately. Relieved twice, £20. Voted £10 in two instalments.—Daughter, aged 62, of L.S.A. Lond. who practised at Cheadle and died in 1874. Owing to ill-health and advancing years, unable to undertake permanent work. Friends allow her £25 a year. She earns about £5 by sewing. Relieved 11 times, £100. Voted £15 in 12 instalments.—Widow, aged 45, of L.S.A. Lond. who practised at Swansea and died in 1915. Was left entirely without means with three children. The eldest was taken by a relative, and the daughter, now aged 17, is being educated by the Guild. Applicant has had post as working housekeeper, but has recently had to give this up. Relieved once, two years ago. Voted £10 in two instalments.—Wife, aged 50, of M.R.C.S. Eng. who practised at Bournemouth. She and her daughter were deserted by her husband some years ago, being left entirely without means. The applicant is a chronic invalid, and the daughter is only able to earn a little by casual employment. Relieved four times, £38. Voted £12 in 12 instalments.—Widow, aged 63, of L.R.F.P.S. Glasg. who practised at Irvine and died in 1899. Applicant left without means, and she suffers from chronic rheumatism and sciatica. Manages to earn a little by letting rooms, but not sufficient to live on. Relieved three times, £36. Voted £12 in 12 instalments.—Daughter, aged 58, of L.S.A. Lond. who practised at Bow and Forest Gate. Applicant has to look after invalid father, who is an annuitant of the Fund, and owing to the high price of food finds it difficult to manage. Relieved once, £10. Voted £10 in two instalments.—Daughter, aged 41, of L.S.A. Lond. who practised at Bermondsey and died in 1887. Applicant's mother, who has just died, had

recently been helped by the Fund. The Guild propose training applicant as a shorthand typist, and placing her in a position to earn her own living. Voted £5.—Daughter, aged 51, of F.R.C.S. Eng. who practised at Biggleswade, and died in 1890. Applicant is a chronic invalid and unable to undertake any permanent work. Relieved 18 times, £165. Voted £12 in 12 instalments.—Daughter, aged 51, of M.R.C.S. Eng. who practised at Peckham and died in 1885. Applicant suffers from neuritis and defective eyesight and was only able to earn £2 last year. Only other income £20 from sister. Relieved 19 times, £221. Voted £15 in 12 instalments.—Daughter, aged 57, of M.R.C.S. Eng. who practised in London and other places and died when applicant was a child. For many years applicant had a very strenuous time, and last year commenced as a munition worker and was doing well, but was unfortunately knocked down by a 'bus in December last and was in the infirmary for almost four months. Is now staying with relations, who are unable to keep her. She hopes to get some compensation. Relieved twice, £10. Voted £12 in 12 instalments.

Subscriptions may be sent to the acting honorary treasurer, Dr. Samuel West, at 11, Chandos-street, Cavendish-square, London, W. 1.

Mr. V. Warren Low, C.B., M.D., F.R.C.S., has been appointed External Examiner in Surgery to the London University.

THE death is announced of Dr. J. Mitford Atkinson, for many years superintendent of the Government Civil Hospital at Hong-Kong.

THE DALRYMPLE INEBRIATE HOME.—The report of the Homes for Inebriates Association for the year ending Jan. 31st, 1917, includes the report for that year of Mr. F. S. D. Hogg, the medical superintendent of Dalrymple House, Rickmansworth. Mr. Hogg makes the interesting comment, in noting that readmissions have during the year been unusually numerous, that this has been due to good but ill-timed intentions on the part of the patients. "Men," he says, "have been over-anxious to obtain admission into the Army or Navy, or to return to a business or profession which is being neglected owing to scarcity of staff or substitutes, or they have been hit by the war and cannot afford to be away from their work. Whatever the reason, the period of treatment is curtailed, and a strenuous life has to be faced by one who is not yet fit to undertake such duties and who has not yet sufficiently recovered from the effects of alcohol or drug addiction."

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Venereal Disease Act.

THE Venereal Disease Act, 1917, has received the Royal Assent.

Whitsuntide Recess.

Parliament has adjourned for the Whitsuntide Recess.

HOUSE OF COMMONS.

WEDNESDAY, MAY 23RD.

Medical Re-examinations.

Mr. HOGGE asked the Under Secretary for War whether a discharged man recalled for examination under the Military Service (Review of Exceptions) Act could insist upon the Medical Board producing his medical history.—Mr. MACPHERSON replied: The answer is in the negative.

Epileptics and the Army.

Mr. HOGGE asked the Under Secretary for War whether there was an Army Order which forbade the discharge of epileptics from the Army.—Mr. MACPHERSON answered: The instructions issued on Dec. 9th on this point lay down that a soldier suffering from epilepsy will not be discharged on that ground alone unless his incapacity is such as to unfit him for any military employment suitable to C 3 men. He will be re-classified in a category from which men are eligible for transfer to Class P or P (T) of the Reserve.

THURSDAY, MAY 24TH.

Fees of R.A.M.C. Officers.

Sir G. TOULMIN asked the Financial Secretary to the War Office whether a captain in the Royal Army Medical Corps serving in a military hospital was entitled to charge a fee for filling up a statement required by a life association in reference to a man who had died under his charge.—Mr. H. FORSTER wrote in reply: I am not aware why any fee ordinarily payable by a life association should not be charged.

FRIDAY, MAY 25TH.

Medical Re-examinations.

Mr. NEEDHAM asked the Under Secretary for War what procedure was open to a man called up for examination under the Military Service (Review of Exceptions) Act, 1917, who was dissatisfied with his medical classification, to have his case submitted to a Medical Appeal Board.—Mr. MACPHERSON replied: An application to be examined by a special Medical Board is submitted for the consideration of the War Office by the military representative in a case where such examination is recommended by a military service tribunal before which the man concerned has laid his case.

Mr. PRINGLE: Are we to understand that he cannot get an appeal to a special Medical Board except through a tribunal?—Mr. MACPHERSON: That is so.

Replying to Mr. NEEDHAM, Mr. MACPHERSON said: The special Recruiting Medical Board at Leeds deals with cases of disputed medical classification of men resident in the North of England which tribunals recommend should be sent to an Appeal Board. The recommendations of the tribunals are submitted to the War Office along with the necessary documents in each case. Men sent to the special Medical Board for examination are provided with travelling warrants and with subsistence if detained overnight.

Answering Mr. T. TAYLOR, who asked whether examinations of recruits by the Medical Boards had frequently been made at the rate of 30 per hour, Mr MACPHERSON said that he was not aware of any instance in which recruits had been examined at the rate mentioned. Express instructions had been issued that examinations under the Military Service (Review of Exceptions) Act should be most careful. The classification certificate was signed by the president of the board.

In the course of the debate on the adjournment motion, Mr. MACPHERSON said that members of Medical Boards were just as sympathetic to men called up for examination under the Military Service (Review of Exceptions) Act as any Members of the House of Commons. At least 75 per cent. of the members of the Medical Boards were civilian practitioners. It was the invariable practice that two of every three doctors on those boards were civilians, and if it were true—and he thought it was true—that there was a proportion of two-thirds of three members of the board civilian, then to say that two-thirds was dominated by the remaining third passed his comprehension.

Cromarty Camp Hospital Huts.

Mr. ANDERSON asked the Under Secretary for War whether 25 of the huts in the Cromarty Military Camp were being used for cases of venereal disease.—Mr. MACPHERSON replied: No, sir. The scheme has been abandoned and other arrangements will be made.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

COLLINS, P., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Rathmore District of the County of Kerry.

ROYAL FREE HOSPITAL.—Acting Assistant Physician: CUTHBERT, HAZEL, H., M.D. Lond. Senior Resident Medical Officer: DEARNLEY, GERTRUDE, M.D. Lond. Junior Obstetric Assistant: DIXON, Miss.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

BIRMINGHAM CITY EDUCATION COMMITTEE.—Temporary Assistant School Medical Officer. Salary £300 per annum.

BRIGHTON COUNTY BOROUGH ASYLUM, Haywards Heath.—Assistant Resident Medical Officer for 4 or 5 weeks. Salary £6 6s. per week and travelling expenses.

BRISTOL GENERAL HOSPITAL.—Casualty House Surgeon. Salary at rate of £175 per annum, with board, &c.

BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN.—Female House Physician. Salary £150 per annum, with board, &c.

BRISTOL ROYAL INFIRMARY.—House Physician and House Surgeon. Salary at rate of £120 per annum, with board, &c.

BROMLEY EDUCATION COMMITTEE, Kent.—School Medical Officer. Salary £300 per annum.

CAPE TOWN, SOUTH AFRICAN COLLEGE.—Professors of Pharmacology, Pathology, and Bacteriology. Salary at rate of £800 per annum each.

CARDIFF, KING EDWARD VII.'S HOSPITAL.—House Surgeon for six months. Salary at rate of £175 per annum, with board, &c.

CHESTER ROYAL INFIRMARY.—House Physician and Assistant House Surgeon. Salaries £150 per annum, with board, &c.

DARLINGTON GENERAL HOSPITAL.—House Surgeon. Salary £200 per annum, with board &c.

DEVONPORT, ROYAL ALBERT HOSPITAL.—House Surgeon, unmarried. Salary £150 per annum, with board, &c.

GRIMSBY AND DISTRICT HOSPITAL.—House Surgeon. Salary £5 5s. per week, with board, &c.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton. House Physician for six months. Salary 30 guineas. Also Resident Medical Officer. Salary £200 per annum, with board, &c.

ITALIAN HOSPITAL, Queen-square, London, W.C.—House Surgeon for six months. Salary £80 per annum, with board, &c.

LEICESTER EDUCATION COMMITTEE.—Two Assistant School Medical Officers (Temporary). Salary £300 per annum.

LIVERPOOL EYE AND EAR INFIRMARY, Myrtle-street.—Female House Surgeon. Salary £150 per annum, with board, &c.

LONDON COUNTY ASYLUMS, Bexley, Kent, and Long Grove, Epsom.—Temporary Assistant Medical Officers. Salary 6 guineas per week, with board, &c.

MANCHESTER CHILDREN'S HOSPITAL, Pendlebury, near Manchester.—Two Female Resident Medical Officers, unmarried. Salary at rate of £100 per annum.

MANCHESTER, CORPORATION OF.—Temporary Assistant Tuberculosis Officer. Salary £450 per annum.

MILITARY HOSPITAL, Richmond, Surrey.—Whole-time Medical Officer. Salary 24s. per diem.

NEWCASTLE-UPON-TYNE, ROYAL VICTORIA INFIRMARY.—Resident Medical Officer. Salary as arranged, with board, &c.

NEW HOSPITAL FOR WOMEN, Euston-road.—Female House Physician, Obstetric Assistant, Two House Surgeons. Salary £50 per annum, with board, &c. Also Resident Medical Officer at House of Recovery, New Barnet. Salary £60 per annum.

NOTTS EDUCATION COMMITTEE.—Assistant School Medical Officer. Salary £350 per annum.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—District Resident Medical Officer for four months. Salary at rate of £60 per annum, with board, &c. Also Pathologist and Registrar. Salary at rate of £80 per annum, with lunch.

QUEEN MARY'S HOSPITAL FOR THE EAST END, Stratford.—Casualty Officer.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—House Physician, Casualty House Surgeon, and House Surgeon for six months. Salary £100 per annum, with board, &c.

ROYAL FREE MILITARY HOSPITAL, London, W.C.—Assistant Resident Medical Officer.

SHEFFIELD, JESSOP HOSPITAL FOR WOMEN, GYNÆCOLOGICAL AND MATERNITY DEPARTMENTS.—Junior Female House Surgeon, unmarried. Salary £200 per annum, with board, &c.

SHEFFIELD ROYAL INFIRMARY.—House Physician. Salary £120 per annum, with board, &c.

SOUTH LONDON HOSPITAL FOR WOMEN, South Side, Clapham Common, S.W.—Female House Surgeon for six months. Salary at rate of £100 per annum, with board, &c.

STOCKPORT, COUNTY BOROUGH EDUCATION COMMITTEE.—School Medical Officer. Salary £300 per annum.

SWANSEA EDUCATION COMMITTEE.—Female Assistant School Medical Officer. Salary £300 per annum.

WORCESTER, KING EDWARD VII. MEMORIAL SANATORIUM, Knightwick, near Worcester.—Temporary Medical Superintendent and Tuberculosis Officer. Salary £450 per annum, with board, &c.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Chew Magna, Somerset.

Births, Marriages, and Deaths.

BIRTHS.

BROWN.—On May 23th, at Adelaide, South Australia, to Dr. and Mrs. Gilbert Brown, of Snowtown, South Australia, a son. (By cable.)

DAW.—On May 20th, at a nursing home, Leeds, the wife of S. W. P. Daw, F.R.C.S., Captain, R.A.M.C., T., Park-square, Leeds, of a son.

HALL.—On May 24th, at a nursing home, the wife of Fleet-Surgeon J. Falconer Hall, Royal Navy, of a daughter.

REW.—On May 25th, at "Wotton Grange," Bedfont, Middlesex, the wife of Lieutenant G. Russell Rew, R.A.M.C., of a son.

MARRIAGES.

HEBBLETHWAITE—KING.—On May 24th, by licence, at St. George's Church, Leeds, Captain Arthur Stuart Hebblethwaite, M.C., R.A.M.C. (T.), to Elsie Langtry, second daughter of Mr. W. H. King, Bollerton, Cheshire.

ROBBINS—DUCHESNE.—On May 28th, by special licence, Captain Frank Hubert Robbins, R.A.M.C. (T.), to Dorothy Muriel Duchesne, elder daughter of Ernest Collier Duchesne, of Oakwood, Bishop Stortford, Herts.

DEATHS.

ATKINSON.—On May 23rd, at his residence, Comeragh-road, West Kensington, W., John Mitford Atkinson, M.B., aged 60.

CODD.—On May 24th, at Holwood Lodge, Bromley, Kent, of pneumonia, Arthur Frederick Gambell Codd, F.R.C.S., aged 60.

DAPHTARY.—On May 26th, at St. Peter's-square, Hammersmith, Surgeon-Major G. R. Daphtary, I.M.S., retired.

POPE.—On May 4th, officially reported missing, believed drowned on the occasion of the torpedoing of s.s. *Transylvania*, Charles A. W. Pope, M.A., M.B. Cantab., Captain R.A.M.C.

SMITH.—On May 23rd, at a nursing home after a brief illness, Thomas Smith, M.R.C.S., L.R.C.P., aged 47.

TILBURY.—Missing, and believed drowned in the Mediterranean on May 4th, Captain Arthur Tilbury, R.A.M.C., M.R.C.S., L.R.C.P. Lond., aged 29.

WOODROFFE.—On May 21st, John FitzHenry Woodroffe, M.D., of Conna, Shankill, co. Dublin, late of Craven Park, Harlesden, N.W., aged 61.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE VICTUALLING OF THE ROYAL NAVY.

AN appeal for contributions of vegetables and fruit in large quantities for the Navy, issued a few weeks ago, serves to draw attention to the fact that the food-supplies of civilians and the Army have been far more freely discussed than those of the Navy. Nevertheless, diet and disease, especially on board ship, is a subject of continued interest and speculation. In 1903 a little book of 30 pages was written by Dr. Alexander Turnbull, Inspector-General of Hospitals and Fleets (retired), and published by Elliot Stock at the price of 1s., entitled "The Victualling of the Royal Navy, Past, Present, and Future: A Practical Statement compiled from State Papers, Historic Documents, and Official Sources, 1486–1903 and After." The author says:—

> Owing to the courtesy of the Director and the Assistant Director of Victualling, I am enabled to furnish a chronological record of the more important improvements in the naval ration, premising that of late years there has been great improvement in the quality of the provisions supplied. In 1804 sugar and tea were introduced as substitutes for butter and cheese, and by 1824 had replaced those perishable articles. Surgeon Thomas Trotter, M.D., R.N., in his memorable treatise on scurvy (London, 1792), furnishing valuable evidence as to the victualling of the Navy in his time, indicated the authorised issue of cocoa at the end of the eighteenth century. A vegetable ration was introduced between 1806 and 1810; it is, however, possible that by means of the legalised and the prior non-legalised system of "savings" the seamen may have been able to purchase vegetables in harbour on their own account. Beer as a ration was finally abolished in 1831, but on foreign stations long prior to this spirits and wine had of necessity been substituted. In 1832 chocolate was substituted for cocoa, and a most popular substitution this proved to be; "ship's cocoa," as it is called, is an excellent breakfast beverage, sustaining and restorative. In the "sixties" several improvements in naval victualling were introduced; pepper and mustard were added in 1860. Preserved meats were reintroduced, preserved potato, rice, and celery seed, as a flavouring for pea-soup, were introduced into the seaman's dietary in 1867. Soft bread, when in harbour and it can be procured, was authorised as an alternative for biscuit in 1868, and in the same year soluble chocolate was supplied for special issues, in stress of weather, &c., it being more expeditiously prepared than chocolate ordinary, which requires prolonged boiling in its preparation. The final addition was salt.

Reference is made to the preserved meats as supplied to the Victorian Navy in the first instance:—

> The first preserved meats were supplied by Mr. Goldner, of Galatz, in Roumania, where cattle were cheaper than in this country. The first contract was in 1844, for five years, and then renewed. Goldner was a name familiar to naval officers in the "fifties," and long afterwards execrated by "all hands" in the Fleet, in connexion with these atrocious supplies, which were condemned wholesale in the naval victualling yards and afloat as unfit for human food, as it was known that they had been supplied to our Arctic explorers' ships. Some tins were found to contain offal, and some maintained—for which, however, there is no official support, as for the offal—that horses' hoofs and even shoes had been found "canned" by Goldner; numerous tins were bulged by the putrescence of their contents, indicating that their varied contents had not even been effectively preserved.

THE COST OF STARTING A COTTAGE HOSPITAL.

To the Editor of THE LANCET.

SIR,—I live in a village of some 800 inhabitants 16 miles from the nearest hospital town by road and much more by rail. There are 8–10 villages in a short radius similarly situated. We desire after the war to start a real cottage hospital with three or four beds, which would also serve as headquarters for, say, two district nurses. I should be much obliged if any of your readers could give me any information as to cost, &c., from their own experience in similar cases.

I am, Sir, yours faithfully,

May 24th, 1917. N. G.

THE TEACHING OF SEX HYGIENE.

WE have received from the National League for Physical Education and Improvement a series consisting of a pamphlet and four leaflets designed to give parents help in instructing their children in a subject which presents many difficulties, but which is of great importance to the welfare of the child. The pamphlet is by Mrs. House, and is in the form of an address to parents on the moral training of boys and girls, the leaflets being intended to be read respectively to a little child, a boy of 12 to 14, a girl of 11 to 13, and older boys and girls. Their aim is to encourage boys and girls to treat their bodies reverently and not hesitate, through a sense of false shame, to seek from older persons and responsible teachers the information for which the coming of adolescence may prompt a desire. The price of the series is 5*d.* from 4, Tavistock-square, London, W.C.

A SANCTUARY FOR LITTLE PILGRIMS.

UNDER this title Messrs. John Bale, Sons, and Danielsson are publishing at the price of 1s. an illustrated record of the progress of the work of the Sanatorium for Tuberculous Children at Harpenden, Herts, which is a special branch of the National Children's Home and Orphanage. The account is written by Dr. T. N. Kelynack, medical adviser to the Home and visiting physician to the Sanatorium, and there is an introduction by Sir Charles Wakefield, Lord Mayor of London, one of the treasurers, and a foreword by the Rev. William Hodson Smith, the principal. The National Children's Home and Orphanage, which has 15 branches in England and Wales and a centre in Canada, has over 2500 destitute and distressed children in its care and is doing an excellent work. The sanatorium, which was opened in June, 1910, has well justified its existence. Educational training is provided for all children of school age, an open-air school being, of course, a special feature. Even without the letterpress the pictures in the little book themselves tell the story of sickness relieved and children's lives made happy. The London offices of the institution are 104–122, City-road, E.C.

FLOUR VALUE.

To the Editor of THE LANCET.

SIR,—The amount of our labour being dependent on our food supply, and this owing to present conditions limited, would it not be wise for the Food Controller to have every sack of flour labelled with the composition and qualities of its contents? Many cases of indigestion come before me, said to be due to the bread not being perfectly made. At this one is not surprised, as the baker little knows what he is using, and is possibly making experiments at the public expense; if he knew the material he was dealing with, I think the public would be better supplied. "To be forewarned is to be forearmed."

I am, Sir, yours faithfully,
JOHN MCOSCAR, L.R.C.P.Lond., M.R.C.S.Eng.

Buxton, May 13th, 1917.

Justice.—We are not aware of the circumstances in which the Essex Insurance Committee may have refused to allow insured persons to make their own arrangements for medical treatment, but we point out that in the report in our article the London Panel Committee expressly referred to the small number of applications made to them to that effect, and drew a conclusion which does not appear unreasonable.

Medical Diary for the ensuing Week.

SOCIETIES.

RÖNTGEN SOCIETY, at the Cancer Hospital (Free), Fulham-road, S.W.

TUESDAY.—8.15 P.M., Annual General Meeting. Election of Officers and Council for the Session 1917–1918. Adjourned Discussion on the Future of the British X Ray Industry (opened by Capt. R. KNOX). Lieut.-Col. R. Wilson, C.A.M.C., Mr. J. H. Webb, and Mr. H. C. Head are expected to take part.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patients (Mr. E. Gillespie). 2.30 P.M., Medical Out-patients (Dr. T. R. Whipham): Gynæcological Out-patients (Dr. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

TUESDAY.—2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. Howell Evans); Nose, Throat, and Ear Out-patients (Mr. C. H. Hayton). Radiography (Dr. Metcalfe). 3.30 P.M., Medical In-patients (Dr. A. J. Whiting).

WEDNESDAY.—Clinics:—2.30 P.M., Throat Operations (Mr. C. H. Hayton). Children Out-patients (Dr. T. R. Whipham); Eye Out-patients (Mr. R. P. Brooks); Skin Out-patients (Dr. H. W. Barber). 5.30 P.M., Eye Operations (Mr. R. P. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patients (Dr. A. J. Whiting); Surgical Out-patients (Mr. Carson); Radiography (Dr. Metcalfe). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

FRIDAY.—2.30 P.M., Surgical Operations (Mr. Howell Evans). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. E. Gillespie); Eye Out-patients (Mr. R. P. Brooks).

ROYAL INSTITUTE OF PUBLIC HEALTH, Lecture Hall of the Institute, 37, Russell-square, W.C. 1.

Course of Lectures and Discussions on Public Health Problems under War and After-war Conditions:—

WEDNESDAY.—4 P.M., Lecture VIII.:—Mr. B. S. Rowntree: Welfare Work in Factories. Followed by a discussion.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.*

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C. 2.

MANAGER'S NOTICES.

ALTERATION IN THE PRICE OF "THE LANCET."

INCREASED war expenses and cost of production necessitate an increase of the price of THE LANCET. Commencing with the new year, the price was raised to 8*d*. The rates of subscription remain as revised in October.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C. 2, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION is published in time to catch the weekly Friday mails to all parts of the world.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given on page 6.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, May 30th, 1917.

Date.	Rainfall.	Solar Radiation in Vacuo.	Maximum Temp. Shade.	Min. Temp.	Wet Bulb.	Dry Bulb.	Remarks.

A Lecture ON DIGITALIS IN AURICULAR FIBRILLATION.[1]

Being the Sydney Ringer Memorial Lecture delivered at University College Hospital Medical School

BY ARTHUR R. CUSHNY, M.D. ABERD., F.R.S.,
PROFESSOR OF PHARMACOLOGY, UNIVERSITY COLLEGE, LONDON.

GENTLEMEN,—From the first introduction of digitalis into therapeutics its influence on the rate of the heart was recognised. The statement of the early writers generally runs that the pulse is slower and more regular, but this is much more pronounced in some cases than in others; and it is the general feeling that it is most marked in very irregular pulse. This slow pulse of digitalis, which was the only objective change in the circulation which could be observed by the methods of the time, received much attention from clinicians in the first half of the nineteenth century, but no further progress was made until Traube in 1851 showed that in mammals large doses injected intravenously slowed the pulse by stimulation of the vagus centre, and after some discussion this was generally accepted as the explanation of the slow pulse observed in clinical cases treated with digitalis. The stimulation of the vagus centre is undoubtedly the cause of the slowing in experimental animals under digitalis, for it disappears when the vagi are cut or paralysed with atropine. More than a century after the introduction of digitalis the knowledge of its therapeutic action had made but little further progress, and was meagre and unsatisfactory. During the last 20 years, however, considerable advance has been made owing to the introduction of the new methods of analysing cardiac arrhythmias.

AURICULAR FIBRILLATION.

In 1905 Mackenzie differentiated a special form of heart irregularity in which digitalis proved especially valuable and in which it generally caused a more marked fall in the rate of the pulse than in other forms of heart disease. This irregularity was that now known to arise from auricular fibrillation. In other conditions digitalis is no doubt of value and it also slows the pulse, but in auricular fibrillation with a rapid and extremely irregular pulse it is almost a specific, and here the slowing of the pulse proceeds parallel with the general improvement, while in other conditions the two effects show no such definite relation; in these the pulse may be slowed without the general condition being better or there may be no significant change in the pulse, while the breathlessness and other symptoms are alleviated. On looking over the older records one recognises that in the cases in which digitalis was most effective and caused the greatest slowing of the pulse the condition was in all probability what is now known as auricular fibrillation.

I may remind you that in auricular fibrillation the pulse is characterised by extreme irregularity in rhythm and in strength and the force of the beat bears no definite relation to the length of the preceding interval. The venous pulse tracing (Mackenzie) and the electro-cardiograph (Lewis) give no indication of a true auricular contraction, and in accordance with this a presystolic murmur present before the inception of fibrillation disappears on its onset (Mackenzie). The electro-cardiograph shows that the auricle is not at rest, however, by a series of minute oscillations which persist throughout.

The interpretation of these conditions is that the pace-maker has lost its leadership and that its regular beating has been superseded by multitudinous impulses which arise from many points of the auricle and keep that chamber in continuous incoördinated activity; one fibre relaxing while another contracts, no change in the total volume of the chamber results, and blood is not driven into the ventricle. This mob of impulses from the auricle in passing to the ventricle is reduced in number by the auriculo-ventricular band being unable to transmit them rapidly, and it may be supposed that of those which actually reach the ventricle a certain number are ineffective through striking it at a refractory period in its cycle. But enough of them pass to it to cause a very irregular rhythm, and this is accompanied by a marked loss in efficiency, as is shown by a fall in the blood pressure which ensues at once when the regular rhythm of the heart gives way to auricular fibrillation.

ACTION OF DIGITALIS.

Under suitable quantities of digitalis in this condition the pulse becomes slower and the beats are less unequal in strength. If the drug is pushed, the pulse may run down to about 40 and become quite regular and equal. And as the pulse falls in rate the general condition improves in the most unmistakable way, breathlessness, dropsy, and lividity disappearing rapidly. The rate of the blood-flow through the peripheral vessels has been measured by Stewart and Scott, who found it quickened as the pulse falls in this condition.

This change is not due to any change in the condition of the auricle, which continues to fibrillate as before, as is shown by the character of the venous pulse remaining unchanged (Mackenzie) and by the persistence of the oscillations in the electro-cardiogram (Lewis). The impulses must therefore be generated in the auricle as before the treatment began, but they can no longer act upon the ventricle in such profusion, and it therefore beats more slowly and more regularly. The conduction of impulses from auricle to ventricle is less rapid then before digitalis was given (Lewis). This salutary impairment of the conductivity can be induced by stimulation of the vagus in man and in animal experiments during auricular fibrillation, while the oscillating contractions in the auricle remain unchanged by the inhibition—that is, the effects under digitalis may be exactly simulated by stimulation of the vagus, and it was therefore natural to attribute the action of the drug in auricular fibrillation to its stimulating the vagus centre in the way which has been shown in normal rhythm in man and animals. The pleasant harmony between the clinical and the experimental results appeared to be unimpaired.

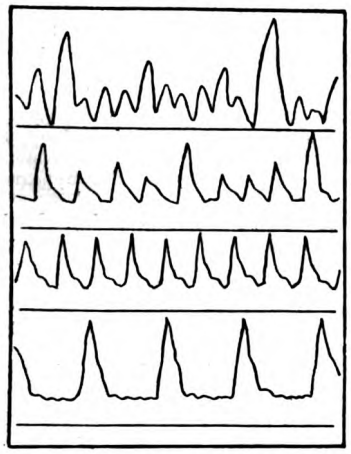
But in a number of observations which I made in Mackenzie's wards along with Marris and Silberberg we satisfied ourselves that in auricular fibrillation the change in conduction is not inhibitory in nature, for it is not prevented by complete paralysis of the vagus by atropine; it must therefore arise from some direct action on the connecting tissue.[2]

On the other hand, the slowing observed under digitalis in most other cardiac conditions in man was removed by atropine; here the action was induced through the inhibitory mechanism. In experiments on animals, I found that when the vagus was cut or paralysed with atropine, digitalis did not slow the pulse and the conduction remained unimpaired until an advanced stage in poisoning far beyond that seen in the therapeutic use. Even when auricular fibrillation was induced in these experiments by electrical stimulation, the irregularity persisted unchanged by digitalis if the vagi were previously put out of action.

We have thus two types of digitalis action in the heart. In the first, which may be called the normal reaction, the heart is slowed through excitation of the inhibitory mechanism. This occurs in hearts in normal rhythm both in man and animals. The second or anomalous reaction occurs only in the auricular fibrillation in man and not in that experimentally induced in normal animals; here the heart is slowed by direct action on the muscle independently of the inhibitory mechanism.

There thus appeared to be a specific reaction in auricular fibrillation in man which differed from that known else-

[1] Fuller details of the experiments will be published in a paper in the Journal of Pharmacology and Experimental Therapeutics.



[2] This view has been contested by Sutherland in the Lumleian Lectures (THE LANCET, March, 1917), who points out that the inhibitory mechanism is excited in a high degree by digitalis and that doses of atropine may be unable to paralyse it under this excitation, though they suffice to put it out of action in ordinary conditions. This objection arises from a misconception. Digitalis excites the vagus inhibitory centre in the medulla, while atropine paralyses the terminations in the heart, and their action is thus not antagonistic on the same tissue, and the excitation does not oppose the paralysis. This is shown by the fact that when atropine has been used electrical stimulation of the vagus does not slow the heart, however much the strength of the shocks is increased. In the same way, however much digitalis excites the inhibitory centre, the impulses fail to affect the heart after atropine. No amount of excitement and shouting at one end of a telephone wire will be effective if the other end is disconnected from the receiver.

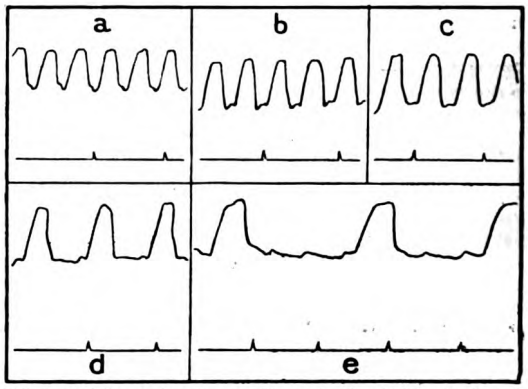
where. It is true that some analogies are presented in experimental conditions. Thus it was shown by Fagge and Stevenson (1865) that in the frog digitalis often causes intermission of the ventricle, while the auricle continues in its ordinary rhythm, and this irregularity is now known to be due to failure of the conduction through direct action on the heart, for it continues after atropine. Similarly in a late stage of poisoning in mammals digitalis interrupts the passage of impulses along the auriculo-ventricular fibres through a direct action on them. But these analogies can hardly be applied to the problem of auricular fibrillation in man, for the frog is too distant a relation to the sick patient, and the impairment of conduction in mammals from direct action occurs only in a late stage of poisoning.

EXPERIMENTS ON THE ANOMALOUS REACTION TO DIGITALIS.

It seemed possible that the anomalous reaction was peculiar to the form of auricular fibrillation in the human heart, and this unsatisfactory view could only be refuted by changing the condition of the mammalian heart so that it too would give the anomalous reaction. During the last two years I have succeeded in doing this in the surviving heart of the rabbit and cat perfused with Ringer's solution. When the perfusion has been carried on for some time—20 to 30 minutes—and auricular fibrillation is excited by electrical stimulation, the administration of strophanthin slows the beat of the ventricle and makes it more regular, while the fibrillation of the auricle continues unchecked. (Fig. 1.) This occurs though the vagi have been cut in the preparation and though the peripheral mechanism is paralysed by atropine added to the Ringer. Finally a slow, perfectly regular beat is observed in the ventricle, while the auricle continues to fibrillate; the multitudinous impulses emitted by it fail to react on the ventricle, which takes up its own slow rhythm. The reaction to digitalis of these perfused hearts in auricular fibrillation is thus exactly analogous to that of the human heart in spontaneous auricular fibrillation.[3]

FIG. 1.

Tracings of the perfused rabbit's ventricle during auricular fibrillation from electrical stimulation. The highest tracing was taken before strophanthin was applied, the second after it had begun to produce its effect, and the third and fourth after the ventricle had become regular. The fibrillation persisted in the auricles.



The anomalous reaction is therefore not specific to man, but is also elicited in animals under abnormal conditions.

The two types of digitalis reaction may thus be elicited at will in animals according to the method of preparation. There seemed a prospect that some light might be shed on the condition of the heart in auricular fibrillation in man by an examination of the conditions in which the anomalous reaction was obtained in animals.

I examined the effect of the perfusion of strophanthin 1 : 500,000 of Ringer's solution in the surviving rabbit's heart beating in normal rhythm. The first effect noticed was generally a slowing of the beat of the whole heart, which indicates that the pacemaker was depressed. Sooner or later the ventricle began to miss beats occasionally, while the rhythm of the auricle remained regular; this indicates that the conduction of impulses from auricle to ventricle is impaired and the further progress of this lesion leads to more frequent intermission, half rhythm, and finally to the ventricle only responding to every fourth or sixth beat of the auricle. (Fig. 2.) This action on impulse formation and conduction was unchanged by the addition of atropine to the perfusing fluid, so that it must have arisen from a direct action on the conducting fibres and not from excitation of the intracardiac inhibitory mechanism.

The changes in rate of the perfused heart under strophanthin are accompanied by increased strength of contraction and lessened diastole, but these are common to both the perfused heart and the heart *in situ*, so that they need not occupy us in the present problem. It must be added that the slowing under strophanthin in the perfused heart has been noted by several previous investigators.

FIG. 2.

Rabbit's ventricle perfused. *a*, Normal; *b*, slight slowing from strophanthin; *c*, more marked slowing; *d*, half rhythm; *e*, rhythm of 1 : 4 and 1 : 3; the auricle beats can be seen during the intervals in *e*.

When a heart is perfused with strophanthin and its response is tested to auricular fibrillation at intervals, it is found that during the earlier stage of slowing the auricular excitation has the usual response in the ventricle, but later, before the actual intermissions occur, the irregularity of the ventricle during auricular fibrillation becomes less marked, and still later the ventricle remains fairly regular while the auricle fibrillates. There can be no question that the decreased conduction of the perfused heart under strophanthin is the explanation of the improvement observed from strophanthin in the perfused heart when the auricle is fibrillating.

We have thus two separate reactions to the digitalis group—one which is seen in patients with normal rhythm and in animals with the heart *in situ*, and in which the slowing is inhibitory in character, the other seen in auricular fibrillation both in man and in the perfused mammalian heart, when the slowing arises from direct action on the heart tissue.

THE PART PLAYED BY MALNUTRITION OF THE HEART.

The anomalous reaction seen in the last case is obviously not caused by the auricular fibrillation, for it does not occur in animals' hearts *in situ*, and in addition an analogous change is seen in the perfused heart when no auricular fibrillation is present. Some change in the condition of the heart quite apart from the fibrillation must therefore be the underlying ground for the change in reaction. And as the change can be caused in the animal heart by substituting perfusion for the ordinary circulation, it is interesting to speculate on its nature.

The perfused mammalian heart shows many differences in reaction from the normal heart. It is much more adapted for studies in experimental pathology and therapeutics than for the elucidation of the normal physiology. And, indeed, not much is to be expected of it, for it receives no source of energy except inorganic salts. Even oxygen is given it in inadequate measure, for Evans calculates that the heart perfused with Ringer's solution must receive about three times its weight of fluid per minute to satisfy its oxygen needs, and no perfusion ever approaches this ideal in my experience. The perfused heart is therefore a starved heart, and its starvation (food and oxygen) appears to me the explanation of its anomalous reaction to digitalis. This view is strengthened by the fact that the reaction is seen best when the heart is perfused for some time before the strophanthin is given; apparently the state of nutrition is only reduced slowly, so that if the drug is applied immediately after the perfusion is commenced, the reaction may depart much less from that seen in the heart *in situ*. And further, those observers who have perfused the heart with blood do not seem to have observed any such slowing and block under

[3] After this research was well advanced, Professor Edmunds, who was my collaborator in describing the first case of auricular fibrillation recognised in man, wrote me that he also had observed the occurrence of this reaction in animals in auricular fibrillation, and had demonstrated it to his class repeatedly. He thus discovered it independently and apparently before my experiments.

strophanthin as form the most striking feature of action on the heart perfused with Ringer's solution.

There are, therefore, sufficient grounds for ascribing the change in the reaction of the perfused animal heart to malnutrition. Are we justified in drawing an analogy to the human heart in auricular fibrillation? Is the fundamental factor here the malnutrition, the auricular fibrillation only a secondary one? There are some grounds in support of this view. Thus in two cases in which there was normal rhythm in man we obtained slowing and block from digitalis, and these proved to be due to direct action, for they were not removed by atropine. Thus the human heart can give the anomalous reaction even when the rhythm is previously normal. On the other hand, some cases of auricular fibrillation in man fail to give the anomalous reaction. It is therefore proved that this reaction is not inseparably attached to auricular fibrillation. And there is, on the other hand, evidence that the heart muscle is gravely injured in cases of fibrillation. Thus the irregularity is greater than is accounted for by the fibrillation alone. And the absence of proportion between the strength of the individual beats and the duration of the preceding interval has been ascribed to a condition of the heart fibre somewhat analogous to that which gives rise to the pulsus alternans. There is therefore justification for the view that in the human heart also the essential character is not the auricular fibrillation but the underlying weakness of the heart muscle.

I do not mean to suggest that this debilitated state of the heart is the sole ground for the anomalous digitalis reaction, and that the auricular fibrillation is an altogether independent feature. For if this were the case, it would be impossible to explain why this reaction occurs so frequently in auricular fibrillation and so seldom in other forms of cardiac debility.

The connexion may be somewhat as follows. In extreme malnutrition of the heart, such as is seen in the perfused rabbit's heart, the anomalous digitalis reaction is elicited without fibrillation. In man this state is comparatively seldom seen while the rhythm is of the normal type, but the onset of auricular fibrillation often induces it. That auricular fibrillation is capable of aggravating greatly any inefficiency already present is obvious. For in normal rhythm there is a measured sequence of events, and due time is given for the recovery of the ventricle from its contraction. In fibrillation a constant storm of impulses beats on the ventricle, it has no longer time to recover from its contractions, and the previous debility is aggravated. In addition, the smaller efficiency of the heart in this rhythm is shown by the marked fall in blood pressure, and this must further tend to impair the hard-pressed heart.

The view I would present is that the anomalous reaction of digitalis arises from malnutrition of the heart primarily, but that this state of malnutrition is exaggerated by the demands made on the heart in auricular fibrillation, which thus contributes to the debility and leads to the anomalous reaction secondarily.

In some cases of well-marked auricular fibrillation digitalis has little effect in slowing the pulse, and in these the condition of the heart is less serious. Here there is unquestionably a certain degree of malnutrition, but the ventricle is protected by imperfect conduction from the mob of impulses from the auricle, and the extreme malnutrition which accompanies the very rapid pulse of typical auricular fibrillation is not developed. Digitalis, therefore, does not produce the anomalous reaction.

In the account I have given of the action of digitalis in auricular fibrillation the effective action is the blocking of impulses from the auricle. Another result of digitalis on the animal heart is the increase in the strength of contraction. Does this play no part in the improved efficiency of the heart? This cannot be answered at present, as we have no means of measuring accurately the contraction of the human heart. Undoubtedly the movement is stronger, but this may be due to the slower beat, which allows of a better recovery in the period of rest. In the perfused animal heart the systolic increase occurs at least as soon as the lessened conduction, and this seems evidence in favour of the improved circulation in patients also depending in part on the increase of systole. But the argument, I admit, is not convincing, since in perfusion experiments the dose of digitalis is necessarily larger than that used in man in order to bring on the action within the time-limits of an experiment.

THE TREATMENT OF SOME COMMON WAR NEUROSES.

BY E. D. ADRIAN, M.R.C.P. LOND.,

TEMPORARY CAPTAIN, R.A.M.C.; NEUROLOGIST, CONNAUGHT HOSPITAL, ALDERSHOT;

AND

L. R. YEALLAND, M.D.,

RESIDENT MEDICAL OFFICER, NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN SQUARE, LONDON.

THE war neuroses with which we are concerned are those in which the patient suffers from some objective disorder such as paralysis, loss of speech, &c., without showing any signs of organic change in the central nervous system. These disorders often occur as the result of mental and physical exhaustion, violent explosions, &c., and they often constitute a very serious disability. They form a well-defined group which is readily distinguished from the neurasthenic and psychasthenic conditions where the patients have subjective complaints, headaches, feelings of exhaustion and depression, and very little in the way of physical signs; at the same time it is a difficult matter to find a suitable name for them. Were it not for the stigma attaching to the word, one would not hesitate to class them as hysterical. However, a diagnosis of hysteria is often held to mean that the patient has nothing the matter with him and requires no treatment. This is manifestly absurd in the case of a man who has been stone deaf for months; his disability is real enough and is in urgent need of treatment. As a rule the difficulty can be overcome by speaking of the disorder as functional rather than hysterical. However, the objection to the term functional is that it covers too wide a field. It applies to any condition which has no demonstrable organic basis, and it would include such disorders as neurasthenia and even epilepsy. We need some name for the neurosis which results in the production of objective signs simulating those due to organic disease, and for the present hysteria is the only term we can use. Babinski has coined a word, pithiatism, to take its place, but the word has not yet won acceptance and for the present we have been forced to adhere to the term hysteria in spite of its manifest disadvantages.

The object of this paper is to describe a method which we have found to be extremely useful in dealing with this type of war neurosis. It has been applied in upwards of 250 cases which have included all the most common types of hysterical disorder; we have records of 82 cases of mutism, 34 of deafness, 18 of aphonia, 37 of monoplegia of the arm or leg, 46 of paraplegia, 16 of hemiplegia, and 18 of disordered gaits not associated with organic change. The majority of the cases have been of several months' standing, but in spite of this the treatment has been almost immediately successful in at least 95 per cent. of the cases in which it has been applied.

The method is certainly not new, indeed it is probably employed in some measure by all who have had much to do with functional disorders, and recently several French neurologists have called attention to its value in the treatment of military cases.[1] However, very little reference has been made to it in recent English literature, and it is not easy to find any comprehensive account of the treatment of disorders of the hysterical type in the average text-book of medicine or even of neurology. At most we find a few lines devoted to the subject of treatment, and we are left with the impression that our task is at an end when we have succeeded in establishing the diagnosis. In war-time this is obviously not enough: adequate treatment is essential, and it will make all the difference between a useless burden to the State and a useful civilian or even a useful soldier.

It is quite true that a correct (or rather a confident) diagnosis is the first step. Indeed, the most important part in the treatment of a functional case consists in making up one's mind that the case is functional. To do this presupposes a knowledge of the signs of organic nervous disease

[1] Vincent: Le Traitement des Phènomènes Hystériques par la Ré-éducation Intensive, Tours, 1916. Babinski et Froment: Hystérie-Pithiatisme, &c., Paris, 1917. Rosanoff-Saloff: Considérations Générales sur la Camptocormie. Nouvelle Iconographie de la Salpêtrière, 1916-1917.

and the points of distinction between functional and organic disorders. However, these have been described often enough, and it is our impression that failure in dealing with these cases is as often due to inadequate treatment as to incorrect diagnosis. For this reason we have dealt with the subject of treatment in some detail and have not attempted to discuss points of diagnosis.

The method to be discussed has the advantage that it does not require any special experience (other than that needed to establish the diagnosis), and only demands a certain degree of confidence on the part of the operator. When properly carried out it is extremely rapid and almost invariably successful, even in cases which have been treated by other methods for months or years without result. The method has its limitations, and in particular it does not apply to the exhausted, neurasthenic type of patient who complains of headache, insomnia, &c., and has no physical symptoms, but only to that type of neurosis where the disability is some objective symptom, paralysis, loss of speech, &c.

The Aims of Treatment.

The different forms of treatment in vogue can be best understood by considering the mental characteristics of patients suffering from this form of neurosis. Though it may seem unjustified to make a psychiatric grouping of these cases, yet there are certain mental abnormalities which are present to some extent in nearly every patient. Indeed, anyone visiting hospital wards where functional and organic cases are treated together cannot fail to be struck by the great difference in the mental outlook of the two classes. The chief phenomena underlying the hysterical type of mind are weakness of the will and of the intellect, hypersuggestibility and negativism. The majority of patients are below the average normal intelligence as judged by the Binet-Simon scale, and others who are more highly equipped prove to have an unstable history either personally or in the family. Their hypersuggestibility is shown by the mode of production of their symptoms and by the ease with which the physician can suggest such conditions as anæsthesia, contraction of the visual fields, &c. At the same time there is a pronounced element of negativism which may amount to a mere inertia or to an active, but not necessarily a conscious, resistance to the idea of recovery. Conditions of negativism are often seen on attempts at movement when the antagonistic muscles overact, when the patient moves backwards when he is told to move forwards, &c. The unconscious resistance is often well marked and must be broken down before any results can be obtained. A combination of hypersuggestibility and negativism may seem to imply a contradiction, but the two are not difficult to reconcile. The patient has a fixed idea that he is dumb or paralysed and he resists all criticism of this idea, but outside this he responds to external suggestions much more readily than a normal person. Indeed, the fixed idea is developed as the result of auto-suggestions acting on a mind enfeebled by fear and emotional tension and this auto-suggestion becomes so strong that the patient resists all attempts to undermine his fixed belief.

These facts are important because they show that we must take into account two distinct conditions in considering treatment and prognosis. These are (*a*) the fixed idea which is giving rise to the functional symptom, paralysis, loss of speech, and so forth, and (*b*) the state of mind which has allowed this fixed idea to develop. The fixed idea can be treated successfully by suggestive methods and the patient can be restored to apparent health, but there is no reason to suppose that his mental instability will vanish. He will always be liable to develop hysterical troubles in moments of emotional stress and exhaustion, just as a man with a malformed chest will be liable to attacks of bronchitis. As Pitres said: "En réalité on nait hystérique, on ne le devient pas."

Psycho-analysis.

There is, however, one method of treatment which lays claim to the power of curing not only the hysterical symptoms but also the hysterical mentality. This is the method of psycho-analysis which is based on the idea that the hysterical type of mind is the result of a buried and unfulfilled wish dating from early infancy and concerned with some fundamental sexual longing. The idea was suppressed because it came into conflict with accepted notions of morality and conduct and its repression has led to a permanent state of tension and unconscious mental conflict. The hysterical symptom is supposed to be simply the emotional expression of the repressed desire or of some secondary conflict due to this desire. When the original infantile desire has been unearthed and explained to the patient, the repressed conflict will vanish and with it not only the hysterical symptom but also the state of mind which made this symptom possible.

It is difficult to avoid the belief that suggestion must play a large part in the cure of those cases where the treatment is successful, but it is not easy to judge of the merits of psycho-analysis because its tenets seem to call either for whole-hearted approval or else for whole-hearted abuse, and the middle course is deplored by both parties. However, the method has certain obvious disadvantages, even though we accept everything which has been said in its favour. It entails a considerable degree of training on the part of the operator, and a considerable degree of intelligence on the part of the patient, and it is a process which demands a great deal of time and individual attention. Indeed, the course of treatment may run into years if a serious attempt is made to cure the hysterical mind by purging it of all the accumulated filth of a lifetime; and if the analysis is not carried through as thoroughly as this the state of tension will remain in some degree and the treatment will have little advantage over the much more rapid methods which are concerned only with the alleviation of the immediate symptoms. Whether the result would justify a lengthy psycho-analysis is another matter, but in any case the time at our disposal is not unlimited, and for this reason alone the treatment is best left to special hospitals dealing with specially selected cases.

Treatment of Symptoms.

We may pass on, then, to consider those methods of treatment which aim only at relieving the functional symptoms and do not profess to give the patient a new mind. There are three principles involved in all these methods—namely, (1) suggestion, (2) re-education, and (3) discipline. The aim of suggestion is to make the patient believe he will be cured, and to lead him on from this to the belief that he is cured. Re-education brings the disordered function back to the normal by directing it until the bad habit is lost, and disciplinary treatment breaks down the unconscious resistance of the patient to the idea of recovery.

One might add a fourth line of treatment, which consists in adopting the attitude of Mr. Micawber and waiting for something to turn up. Probably this course is often adopted because there is some doubt as to the diagnosis. When it is uncertain whether a paralysis is functional or organic it is perhaps natural enough to leave it alone in the hope that time will show the difference. Fortunately, a certain number of functional cases do recover when left to themselves, but a large number do not, and expectant treatment may keep a patient for six months in hospital when more vigorous measures would have removed his symptoms in a week. Moreover, the atmosphere of a hospital is distinctly enervating and a functional case is rarely the better for a prolonged stay in the wards even though the symptoms may have improved.

Hypnotism.

As an example of a process which aims at curing by pure suggestion we may instance treatment by hypnotism. The treatment consists in reducing the patient to a state of mind in which his critical faculties are in abeyance and then suggesting verbally that his disability no longer exists. Most hysterical patients, being hyper-suggestible, are very easy to hypnotise lightly. They will readily accept the idea that they cannot open their eyes or move their limbs and they will comply with any suggestion which does not relate to their disability. Unfortunately they are not nearly so tolerant when the suggestion touches their fixed belief that they cannot speak or that their legs are paralysed, and it requires a far greater ascendancy on the part of the operator before they will agree to suggestions which are curative and not merely ornamental. One has only to be hypnotised to realise this state of mind. Unimportant suggestions are readily accepted, but anything which runs counter to one's favourite prejudices is simply dismissed as absurd. With a patient who is intelligent and anxious to get well hypnotism may be extremely successful, and it is certainly of great value in the treatment of subjective troubles such as

insomnia, fighting dreams, &c.,[2] which can scarcely be classed as hysterical. However, in the majority of functional cases where the resistance is at all marked our limited experience of the method has led us to believe that it is slow and uncertain in comparison with vigorous suggestive treatment and re-education.

Isolation.

As an example of treatment in which the disciplinary element is very much to the fore we may instance the use of strict isolation in hysterical cases. This supplies the needful stimulus to recovery by making the patient's illness a dreary and unprofitable business instead of a source of pride and satisfaction. For this reason it is extremely useful in cases of functional tremors and pseudo-chorea where the patient becomes quiet as soon as he is deprived of his audience. It is not suggested that isolation acts in this way in every functional disorder. The frightened, exhausted neurasthenic is often much happier when left to himself with nothing to disturb him, and it would be absurd to regard isolation as a disciplinary measure in such cases. But in those cases where disciplinary measures seem to be indicated we doubt if isolation is an advisable form of treatment. It may eventually force a patient to release his claim to a supposed disorder, but the process may take some time and is rarely as effective as a little plain speaking accompanied by a strong faradic current. Moreover, eight hours' rest out of the 24 is, to our mind, quite sufficient, and extension of that time in one who has no indication of physical illness is more liable to do harm than good. The disciplinary element may be assumed to enter into any form of painful suggestive treatment; it is often unnecessary, particularly in those cases where the disability is irksome enough by itself and the patient is anxious to get well; but in many cases it is a very important part of the treatment since it is the only certain means of breaking down the patient's resistance to the idea of recovery.

Persuasion.

Under the heading of re-education we might include the method of simple persuasion in which the patient is convinced by logical argument that his condition is not so serious as he supposes.[3] The difficulty with this form of treatment lies in the fact that a patient of average intelligence does not easily realise that his physical disability is due to a mental and not to a physical disorder. If an attempt is made to explain the real state of affairs to him he is generally left with the impression that he is suspected of malingering. It seems only natural to him that his cure should be brought about by some physical means, and therefore he will respond to some simple suggestive measure when persuasion or re-education would leave him untouched. In certain cases, notably in mutism and aphonia and in the spastic type of paraplegia, a rapid re-education is often quite enough by itself, but as a rule the patient will have greater confidence if he has received some preliminary suggestive treatment.

Suggestive Treatment and Re-education.

For this reason the method which we have finally adopted consists in a very brief suggestive treatment followed by rapid re-education, which is continued, if possible, without a pause until the normal function is entirely regained. The details will be discussed in dealing with the different functional manifestations, but there are certain general considerations which hold good in every case.

The suggestive treatment may take any form, but it is essential that the patient should be convinced that it will produce an immediate recovery. In untreated cases there is rarely any difficulty in this, and the conviction can be strengthened by using a form of treatment which will be capable by itself of evoking some part of the function which is temporarily in abeyance. For instance, a case of mutism may be cured by tickling the back of the mouth so as to induce reflex phonation. The patient is compelled to make a noise, and the fact that he has done so will convince him that the treatment will be effective. In the same way a strong electric stimulus will produce a sensation and motion in a limb which is supposed to be anæsthetic and paralysed, and this in itself will be enough to convince the patient that he is on the road to recovery. Occasionally this form of treatment has been tried before and has failed because the operator had not enough confidence in the method. In this case it is, of course, useless to repeat the same procedure, and we must fall back on some other form of treatment in which the patient will have greater faith.

The simplest form of suggestive treatment to apply is the faradic current. The therapeutic uses of electricity are still mysterious enough to the layman, and nearly every patient is willing to accept the suggestion that some form of electricity will cure him. The current can be made extremely painful if it is necessary to supply the disciplinary element which must be invoked if the patient is one of those who prefer not to recover, and it can be made strong enough to break down the unconscious barriers to sensation in the most profound functional anæsthesia. The only difficulty arises when the patient has already been subjected to a long course of electrical treatment without result. It often happens that a patient, either from mistaken diagnosis or mistaken ideas of treatment, has been given daily applications of some innocuous form of electricity in the belief that the electricity by itself will do all that is necessary. Such treatment, unaccompanied by the necessary suggestions, is generally quite useless in a functional case, and, as a rule, the only result is to accustom the patient to electrical stimuli and to foster the idea that his case is hopeless. It is easy to satisfy one's self that in these cases the sole value of electrical treatment lies in the suggestive effect it can be made to produce. We have watched a nurse administering the treatment to a paralysed limb, rolling the electrode up and down, sometimes with eyes shut and sometimes with eyes open, to say nothing of an occasional yawn. Needless to say, the patient remained paralysed, and the only result was so much current wasted. On the other hand, the same patient given exactly the same form of electricity with persuasion recovered completely in a few minutes.

When the patient tells us that he has already been treated by electricity it is as well to find out whether the treatment was painful or not. If it was not, the patient will generally yield at once to painful faradisation with a wire brush after he has been informed that this kind of electricity is far more potent than any he has had previously. If this, too, has been tried before, the suggestive treatment must take an entirely different form. As an instance of this we may quote the case, recently treated by one of us, of an officer who had a functional paralysis of the arm which had persisted for two years in spite of prolonged treatment by hypnotism, psycho-analysis, rest, massage, anæsthesia with ether, and electrical treatment which had included several extremely painful applications of electricity to the arm. He knew something of the functions of the brain and took a great interest in his condition, which he was prepared to discuss exhaustively. He was told that he had come to be cured, and that for the present he must be content with this; the nature of the cure would be explained to him afterwards. Without any further discussion the motor areas of the cortex were mapped out roughly, the measurements being repeated aloud to impress and mystify the patient. He was told that as soon as the shoulder area of the cortex was stimulated by faradism he would be able to raise his shoulder and that the rest of the arm would recover in the same way. A very mild faradic current was applied for a few seconds to the scalp, and he was then ordered to move his shoulder. He did so at once, and in a few minutes the whole of the paralysis had disappeared and he could raise 30 pounds. We believe that the success in this case was due in a large measure to the fact that the patient was not allowed to discuss his case or to criticise the proposed treatment. The value of this will be pointed out immediately.

Whatever form of treatment is employed, the patient must be convinced that the physician understands his case and is able to cure him. This idea should be fostered from the moment the patient enters the ward. The case is investigated as briefly as possible, and each physical sign is accepted as perfectly normal in the circumstances, and not as in any way interesting or obscure. The best attitude to adopt is one of mild boredom bred of perfect familiarity with the patient's disorder, and if the case has to be exhibited to anyone else it is shown not as anything unusual, but as a perfect example of the type of case which is cured in five minutes by appropriate treatment. After the examination the patient is met with the absolute assurance that

[2] Cf. Hurst: Medical Diseases of the War, 1916.
[3] Dubois: Psychic Treatment of Nervous Disorders.

he will be cured as soon as the physician can find the time to treat him. He is told that he will not need to stay in hospital for more than a few days, and that he can write and inform his friends of this. It is usually necessary to find out what treatment the patient has had before to avoid the risk of repeating a procedure which has already been tried and found wanting, but apart from this it is better to avoid discussing the case and the methods which will be adopted to cure it. The barest statement should suffice, and the patient should be silenced at once if he attempts to air his own views on the subject. An argument in which the physician does not seem perfectly sure of his ground is likely to weaken his authority at the moment when it should be absolutely unquestioned, and an air of complete assurance is far more convincing than the most elaborate reasoning.

The treatment is best carried out in a special room set apart for the purpose, where there will be nothing to distract the patient's attention. As soon as the least sign of recovery has appeared the re-education is begun. The patient is given no time to collect his thoughts, but is hurried along by a mixture of persuasion and command until the disordered function has completely recovered. The patient is never allowed any say in the matter. He is not asked whether he can raise his paralysed arm or not; he is ordered to raise it, and told that he can do it perfectly if he tries. Rapidity and an authoritative manner are the chief factors in the re-educative process, and in every case an effort should be made to produce complete recovery before the patient goes back to the ward. If the treatment has to be discontinued before recovery is complete the patient should be assured that he will be quite well in 24 hours and the re-education should be continued as soon as possible.

There are many details which are best considered in connexion with particular hysterical symptoms, and therefore we shall describe the most common affections in which the suggestive method is pre-eminently successful. The most common disorder is the complete or partial loss of a normal function, and the most common functions to be lost are those concerned with hearing and speaking and with the sensation and motion of the limbs.

Deafness.

As a rule, the patient is stone-deaf and often dumb as well and there may be associated symptoms, such as loss of vibration sense in the bones of the skull. The patient is told in writing that he will be cured in five minutes by electricity. The suggestive effect may be enhanced by the use of a darkened room, a head mirror, and so forth, but the essential treatment consists in applying a strong faradic current to the side of the head or to the external auditory meatus. The patient is informed that as the feeling comes back the current will appear more and more painful, and that in a very short time he will be able to hear the tick of a watch pressed against his ear. The current is applied for a few seconds at a time and increased in strength between each application. When the patient begins to show signs that the current is painful he is told that the feeling is returning and that he will soon hear perfectly. A watch (or a tuning-fork) is pressed closely against his ear between each application of the current and in less than five minutes he will begin to hear it. After a few more applications of the current he will be able to hear the watch at a distance of a foot or more. Sometimes he is able to hear the ticking of a watch, but is unable to interpret what is said to him. He is then re-educated, beginning with the vowel sounds, then with words of one syllable, then two, and so on, until he can hear perfectly. If the other ear has not recovered at the same time it is a simple process to restore the hearing to it in the same way. The cure is usually complete in less than ten minutes, though it may take longer in patients who have been stone-deaf for a year or more. In a series of 34 cases we have had only one failure. This was in a patient who had been deaf for over a year in spite of every kind of treatment. We saw him for a few minutes only and had no opportunity of continuing the treatment.

We have yet to observe any of the unpleasant after-effects which are said to arise from faradism in the region of the ear. It may produce a transient vertigo, and if it is to be effective it must be strong enough to be painful. The patient may object to this at first, but when the hearing has been restored to one ear he is always perfectly ready to have the same process applied to the ear which is still deaf.

One has sometimes to deal with cases where faradism has failed to produce a cure, The failure is due to lack of determination on the part of the operator; he is either ignorant of the fact that the condition is one which always responds to suggestive measures, or he becomes too easily fatigued to see the thing through to a successful issue. In such cases some other suggestive measure must be adopted; for instance, the application of tuning-forks of different sizes, beginning with those in which the vibrations are slow enough to be felt rather than heard, and reducing the size gradually until the fork can be heard rather than felt. The re-education can then be completed by shouting down a stethoscope. However, in untreated cases we have found the electrical method to be invariably successful in a few minutes.

Mutism.

When this is complicated by deafness it is, of course, natural to treat the deafness first, as this makes communication with the patient so much easier. As soon as he can hear the patient is told that his speech will be restored in the same way. A long pharyngeal electrode is used, and he is told to sound the vowel "ah" as soon as he feels the current. The soft palate and pillars of the fauces are stimulated, and as a rule he phonates loudly as soon as the electrode is applied; he is then told to repeat the other vowels, the letters of the alphabet, numbers, days of the week, &c., and he is soon able to enter into a conversation.

When mutism has existed alone it is often unnecessary to do anything more than tickling the back of the patient's mouth with a mirror or tongue depressor. This evokes some reflex phonation in the form of gurgling or retching, and the patient is then told to say "Ah." The process is repeated until he can do this naturally, and it is then a simple matter to make him sound the other vowels and to repeat the whole alphabet in an audible voice. In still milder cases the patient will phonate loudly when he coughs or gargles, and he can then be made to sound "ah" by gradually eliminating the explosive element of the cough. In some cases the soft palate appears to be anæsthetic, and the patient does not phonate when his throat is tickled. This difficulty can be overcome by applying a faradic current to the back of the throat. In a case which has been previously treated with electricity in this way some new form of treatment must be devised and every effort must be made to strengthen the suggestive effect. However, the condition is one which tends to clear up spontaneously, and most cases respond at once to the simplest suggestions.

The first signs of voluntary phonation must be followed up immediately, and the patient must be given no respite until he can speak perfectly. He is, of course, instructed beforehand that the treatment will effect a complete cure, and he must not be allowed to go back to the ward whispering or stammering, even though he may regard this as an immense improvement on his former state.

Aphonia.

The patient is able to whisper, but cannot phonate properly. This may exist as a stage in the spontaneous recovery of a mute, but it is most often an after-effect of laryngitis. The patient can be made to phonate by tickling his throat or by coughing or gargling, and the whole process is simply one of re-education, which is usually complete in a minute or less. It is rarely necessary to use electricity.

Stammering.

A tendency to stammer sometimes shows itself during the re-education of a mute. It can be checked at once by re-education and simple suggestive measures, such as faradism applied to the back of the neck, but if it is not checked as soon as it appears it may become much more intractable. For this reason patients who have been allowed to recover their voice spontaneously may develop a bad stammer which takes some time to clear up.

Blindness.

We have no direct experience of hysterical blindness in both eyes in military cases. Cases of monocular blindness or of defective vision, with no refractive error and no changes in the retina, are probably more often the result of malingering than of hysteria. Treatment by strong faradism in the region of the supra- or infra-orbital nerves is successful in either case, but it is generally found that the alleged defect can be remedied by a little plain speaking.

Hysterical affections of the other special senses and of the cranial nerves are relatively unimportant, and there is usually no difficulty in devising a suitable form of suggestive treatment.

Paralysis of the Upper Limbs.

Cases of paralysis of one arm are very common and very easily curable. As a rule they occur after some slight wound or bruise which has necessitated the use of a splint. The treatment can best be described by considering a typical case. The patient has received a slight wound of the forearm some months ago, and ever since his whole arm has been useless. He can move it slightly at the shoulder by exerting what appears to be a superhuman effort, and he can occasionally flex the fingers through a small angle. There is complete anæsthesia of the hand and arm, ending in a line drawn horizontally round the elbow. The patient does not necessarily complain of this anæsthesia and there may be no sign of its existence until it is suggested to him by the physician, but it is often useful to elicit it in view of the subsequent treatment. The diagnosis is obvious at once from the absence of wasting, the distribution of the sensory loss, and the involvement of the whole arm after an injury which could not possibly have affected the upper arm and shoulder.

The patient is told that he is very lucky to have come off with such a slight injury, and that his arm will be set right in five minutes by the application of a special form of electricity. He is made to sit on a large pad electrode connected with an induction coil, the other terminal being connected with a wire brush. He is informed that the first effect of the current will be to bring back the feeling in the forearm, and that as the feeling returns the power will return with it. A fairly strong current is turned on, and the wire brush is drawn downwards over the forearm from the elbow to the wrist. After a few applications the patient is told that he can now feel as far down as the wrist, and he is tested with a pin to convince him of the truth of this. If he cannot feel the pin-prick, the current is increased in strength until he can do so. The same process is applied to the hand until this, too, ceases to be anæsthetic. The improvement is pointed out to the patient and he is told that as the feeling has now returned to his arm it will be a very simple matter to restore the power of movement.[4] After a few touches with the electrode designed to produce contraction in the muscles he is told to move the arm. He will do so at first in a hesitating manner with every appearance of great effort, but this will be quite enough to convince him that the power is really returning. The rapid re-education follows at once. He is given no time to think, but urged to move the arm more and more strongly, to grip the physician's hand, to flex and extend the elbow, &c., and the pressure is not relaxed until the whole limb has returned to its normal vigour. If the improvement comes to a standstill before recovery is complete, the faradisation is repeated with stronger and stronger currents. Rapidity and an air of authority which will brook no denial are usually quite enough without this, and if once the recovery is complete there will be little fear of a relapse. If the patient's manner suggests that he is likely to relapse as soon as he leaves the hospital, he is told that this is very unlikely, but that if it should occur he should report sick at once and come back for treatment with a current far stronger than that already used. Needless to say it is rarely necessary to carry out this proposal.

In untreated cases a very mild current is all that is required, but if, as often happens, the patient has been treated before with some form of electricity without suggestion it is better to begin with a current strong enough to be painful. If this has already been tried without success, it is better to adopt some entirely different line of treatment, as in the case of the officer already quoted.

Paralysis of the Lower Limbs.

Cases of monoplegia are treated in the same way as paralysis of one arm. In paraplegia the treatment depends to some extent on the type of paralysis. As a rule, a recent case of paraplegia due to "shell shock" or burial belongs to the flaccid type without exaggerated reflexes. If this is allowed to recover slowly it merges into the spastic variety with pseudo-clonus, exaggerated knee-jerks, and rigidity. Passive movements are resisted strongly, and when the patient attempts to put the flexor group of muscles into action the extensor group contracts at the same time and a condition of increased tone and clonus is set up. The condition is, of course, due to a disordered mental process and not to organic diseases in the central nervous system, and we may regard it as akin to the states of negativism which occur in dementia præcox. Whatever the explanation may be, the fact remains that this condition is very often seen in cases which have been badly treated, and in such cases it is often difficult to eradicate completely in a short time. The spastic condition often occurs during the re-educative treatment of a case of flaccid paraplegia, but it is then of little consequence, as the patient is allowed no time to acquire the habit.

In cases of flaccid paraplegia it is as well to restore sensation and movement to the limbs by treatment with faradism before the re-education is attempted. Otherwise the patient will simply collapse when set on his feet. In the spastic type it is often better to hold the suggestive treatment in reserve and to do as much as possible by re-education alone. The patient is told that all he needs is a little confidence in his legs, and he is then set on his feet and induced to walk. At first the greater part of his weight is taken by the physician, but in a few minutes he is made to bear his own weight and to walk with less and less assistance and more and more rapidly.

Certain details in the treatment deserve mention. It is perhaps unnecessary to insist that slippers without heels are not the ideal form of footgear when the patient is learning to walk. They encourage a shuffling gait, and frequent halts are necessary to readjust them. Indeed, the use of slippers and a stick would perpetuate a limp in any patient who had the least tendency to a neurosis. The re-educative treatment of a patient who cannot walk properly is best carried out in a large empty room, a corridor, or out of doors. He will not feel unduly self-conscious as he would do in a ward full of patients, and he will have nothing to hold on to. If there is no alternative between walking and falling down the patient will usually find himself able to walk (once he has passed the earliest stages in re-education), but if a middle course is offered in the shape of a chair or a bed to which he can cling he will at once seek safety in this, and the more he is allowed to use his hands to support himself the less likely will he be to trust to his legs. At first the patient will seem to be continually on the verge of losing his balance, but, as a rule, there is little fear of this, and the idea should not be encouraged by supporting him whenever he seems in the slightest danger of falling. It is best to allow him as little assistance as possible. To begin with he should walk arm-in-arm with the physician, then facing him and holding his hands, then holding one hand only, and finally with no support at all. A fall should be avoided as far as possible, but it is of no great consequence if it does occur, for the patient will not be taken unawares, and will be unlikely to hurt himself. A fall should on no account be taken as an excuse for resting; it should be treated as a matter of course, and the patient should be made to continue his efforts until he can walk without falling.

If possible the patient should not be returned to the ward until he can walk without assistance of any kind, and on no account should he be allowed to use sticks or crutches, even though he has been paraplegic for six months. Until he has recovered completely he should not be allowed to walk except under the direct supervision of the physician; otherwise he will be liable to develop a functional gait or a limp, and a further re-education will be necessary. As in every functional disorder, it is extremely important to produce a rapid improvement during the first treatment and to continue this at the earliest possible moment until recovery is complete.

Precisely the same form of treatment applies to the patient with functional "rheumatism," who walks with bent and trembling knees and a couple of sticks, functional hemiplegia, functional sciatica, and functional gaits of all kinds. As a rule it is found that the more serious the disability the easier will it be to cure; a case of complete

[4] The layman seems to consider that loss of power and loss of feeling are inseparably connected. One of us asked 100 persons of average intelligence whether they would lose the sensation in their hand if for any reason it became paralysed. Due care was taken to avoid suggesting the answer, but in every case they replied in the affirmative. This idea may account for the development of anæsthesia in functional paralysis, and it is easy to see that a patient will accept the suggestion that his paralysis will recover when his anæsthesia has been cleared up by electricity.

flaccid paraplegia will often walk perfectly after an hour's treatment, whereas a man with a slight functional limp will need a re-education lasting for days or even weeks.

Tremors, Fits, &c.

We have given a detailed account of the treatment of deafness, mutism, and paralysis because these cases are so easily curable with rapid suggestive and re-educative measures. They are all due to the absence or diminished activity of a normal function, and the treatment has only to recall this function to the patient's consciousness. Fortunately these cases form a large percentage of the hysterical war neuroses. There is, however, a group of cases in which the treatment is often successful, but by no means invariably. These cases depend not so much on the absence of a normal function as on its excessive and disordered activity. Functional tremors and incoördination, choreiform movements, and tic-like spasms are examples of this class, and we might include hysterical fits and even the stammering and explosive type of speech. Functional tremors are sometimes very easily cured by a little suggestive faradism, and fits may be stopped temporarily at least by suggestive measures. The patient is induced to have a fit by assuring him that he will do so when an electric current is applied to his forehead, and the fit is checked by supraorbital pressure or faradism to some other part of the body. The patient is then told that his fits are not epileptic and that they have been cured. As a rule he will have no more fits as long as he is in hospital, but he may relapse outside, and we know of several cases where this has happened. Indeed, the method is probably more valuable as an aid to diagnosis than to treatment.

Involuntary movements and hysterical chorea may yield to rapid suggestive methods, but isolation is a more reliable form of treatment, although it is at the best a slow process.

Functional contractures deserve a place by themselves. When they are truly hysterical they will usually yield at once to suggestive faradism with a moderately strong current. But it is sometimes extremely difficult to make certain that the condition has not some organic basis. Babinski and Froment have collected a number of cases described as reflex nervous disorders and having an organic origin, although they show a superficial resemblance to the hysterical contractures.[5] These cases are generally intractable, and so far no line of treatment has been found to have much effect on them. We have seen four or five cases which could be included in this category, and in them suggestive treatment was certainly quite ineffective.

For the sake of completeness we should mention a method of suggestion which is often employed with good results. This consists in anæsthetising the patient and making the necessary suggestions to him as he is going under or coming round from the anæsthetic. To a certain extent the process may be compared with hypnotism in that the suggestions are made at a time when the critical faculties of the patient are dulled; but the main advantage of the method lies in the fact that in the stage of excitement the patient will struggle, cry out, &c., and that he will often regain consciousness whilst he is in the act of moving the arm which was formerly paralysed or using the voice which was formerly dumb. The method demands an anæsthetist who will be able to produce a long excitement stage, and the results are to some extent a matter of luck. This furnishes the chief objection to the method, for if it fails the patient will have some excuse for taking a gloomy view of his case, and he will be naturally sceptical of less heroic methods. However, we have little direct experience of the method, as we have not found it necessary to employ it.

Prognosis and After-treatment.

The treatment of a functional case does not end at the moment when the disability has been cured, and we have always to determine how much the patient may be safely called upon to do without fear of a relapse. This will depend on how far the underlying mental condition is a permanent state and how great a strain was necessary to lead to the development of the symptoms. If the patient gives a history showing pronounced mental instability or previous functional troubles before the war, and if he has lost the use of his legs after a few days in the trenches, it is clear that he will never be of the least value at the front, and he is probably best employed in a labour unit at home or on sedentary work. If he has served several months in the fighting line, and has then lost his voice after a week without sleep and a severe bombardment, he will often be perfectly fit again after a short rest, and he will show only the slightest signs of the hysterical temperament. He may relapse under an equally severe strain, but if his cure has been rapid and complete on the first occasion he will have less reason to fear a relapse and to regard a temporary loss of speech as a serious and intractable condition. It is another matter if he has been allowed to remain dumb for six months in hospital, for in this case he will have every reason to regard himself as the victim of a severe form of "shell shock," and he will probably be quite unfit for service in the fighting line.

In all cases a thorough examination of the past history and mental condition must be made before we can decide what form of service will be most advantageous to the patient and to the nation. In the more intractable conditions—tics, convulsions, &c.—the patient may be able to do some useful work with a labour unit, but it is often better for all concerned to return him to civilian life.

In conclusion, we wish to express our thanks to the medical and surgical staff of the National Hospital, Queen-square, and to Lieutenant-Colonel W. Turner, officer in charge of the Connaught Hospital, Aldershot, for permission to publish these notes.

CHYLO-HÆMOTHORAX FROM WOUNDS INVOLVING THE THORACIC DUCT.

BY T. R. ELLIOTT, F.R.C.P. LOND., F.R.S.,
LIEUTENANT-COLONEL, R.A.M.C.;
AND
HERBERT HENRY, M.D. LOND.,
CAPTAIN, R.A.M.C.

WHEN a fluid obtained by exploratory puncture of the chest seems to be "frankly purulent" to the naked eye one is apt to assume that this appearance is sufficient proof that an empyema is present and that rib resection is justified without any further microscopic study of the specimen.

In nearly all such cases the presumption that infection exists is true, but occasionally a rare example may be encountered in which the thoracic duct has been wounded in the chest without the associated injuries being at once fatal, and then the milky chyle will leak into the effused blood and produce a combination mimicking that of a pyo-hæmothorax so closely that most surgeons would be deceived by it.

The first case quoted in this paper was one in which the error was not avoided and the medical officer was misled by the appearance of the fluid into performing an operation for drainage of the pleural cavity. The patient recovered, but his convalescence was dated by months instead of by weeks in consequence of the mistake. In the second case the character of the fluid was guessed to be chylous and proved to be so before anything was done. But unfortunately the effusion had been infected by the shell fragment which caused the wound and drainage was unavoidable and was followed by death.

The error can only be avoided by holding fast at all times to the general clinical rule: "That *drainage* of a chest after gunshot wound should never be undertaken except upon bacteriological proof of infection in the fluid withdrawn at exploration, or upon the recognition of an offensive smell in the latter." The naked-eye appearance of any fluid may be entirely misleading, as hopelessly, though not so frequently, as is the clinical judgment of a chest wound before exploration is made.

At base hospitals these cases of chylo-hæmothorax must be very few. The two that are described from our own experience did actually occur in the same hospital within a month of one another, but they are the only two that we have seen out of a total of 600 samples of hæmothorax fluid that were examined by us in the laboratory; and this laboratory figure covers a clinical experience of far more than a thousand chest wounds. But the occurrence of a chylous effusion would not appear to be so rare as this, if it were expressed as a percentage of all large effusions on the

left side of the chest. The possibility is certainly a practical point which deserves to be borne in mind when dealing with big traumatic effusions in the left pleural cavity.

Diagnosis.

There are several points which characterise a chylous leak into a hæmothorax.

1. The collection of fluid is on the left side.

2. The effusion continues to increase steadily and rapidly on the third and fourth day, causing progressive cardiac and respiratory embarrassment. Such an increase is rarely seen with an ordinary sterile hæmothorax, where the bleeding is either fatal or ceases in the first 24 hours. It may, however, occur as the result of infection of a hæmothorax. A chylous effusion, even if infected, will not be accompanied by high fever because the patient's nutrition is profoundly impaired; whereas sepsis in a simple hæmothorax generally causes a high temperature.

3. Exploration discovers a fluid which appears to be heavily loaded with pus. If this appearance is seen in a large collection of fluid early in the first week after the wound, it is almost certain that it must not be ascribed to pus, because the processes of pleural suppuration following upon sepsis in a hæmothorax take many days before they can produce an abundant pleural exudate.

4. The fluid is opaque, and its colour will vary from red to pink or creamy-grey in accordance with the proportion of commingled blood. In the two cases that are described below the fluid did not clot after withdrawal from the chest, presumably because its fibrin was being separated by coagulation within the chest as fast as the chyle escaped from the duct.

5. On centrifugalisation a deposit of red cells is thrown down, leaving a supernatant opaque milky fluid whose creamy-white colour contrasts brilliantly with the red band below. Under the microscope the milky fluid is seen to be filled with small fat globules, which are immediately soluble in ether. A few mononuclear leucocytes are scattered among these fat globules.

Anatomy of the Lesion.

The cervical part of the thoracic duct, or one of its branches, has occasionally chanced to be injured in the surgical operations of civil life when extensive dissections are being made in the root of the neck. The records of such cases have been fully collected in a recent paper by E. Harrison.[1]

The intra-thoracic portion of the duct lies in a field that is less exposed to surgery, and its lesions in civil life are for the most part those of spontaneous rupture, which may occur when the duct is obstructed by the pressure of a malignant growth or by the chronic fibrosing inflammation due to filaria parasites. In such cases a collateral circulation is often fairly well developed before the rupture occurs, because the obstruction is slow in being established; and therefore the clinical picture differs from that caused by a wound suddenly severing a healthy duct which was the sole conduit for chyle from the visceral area to the venous system.

In the wounds of war-time the duct is no doubt often torn open by missiles that injure the chest; but its position is so closely related to that of the great vital vessels of the thorax that the bullet which can wound the duct is almost certain to kill by causing fatal hæmorrhage from the neighbouring blood-vessels.

Below the level of the fourth thoracic vertebra the duct is a target which a missile cannot reach without injuring in addition either the heart, the aorta, or the azygos veins. Above this level the duct passes outwards to the left, and it may take a path over the heads of the first three ribs or be displaced even further laterally. In this position the left mediastinal pleura comes into lateral or anterior relationship with it, while the origin of the left subclavian artery is immediately to the front. Here a ball may chance to pass between the vessels springing from the arch of the aorta and to cut the duct without injuring the great veins at the root of the neck.

The possible paths for such an injury may, perhaps, be several in number; but as a matter of experience, in each of the two cases quoted in this paper the track of the missile seems to have been the same, passing obliquely across the apex of the thorax, behind and under the subclavian artery and meeting the duct as it lay near the apex of the lung upon the vertebræ, or perhaps upon the heads of the ribs. This track is roughly parallel to the axis of the heart. It will permit the passage of a large projectile, such as a shrapnel ball, without associated fatal injuries. In our second case it appears likely that the shrapnel ball entering above the right clavicle had attained this path by passing through and splintering the body of a vertebra. It is a common and, indeed, it is the usual occurrence, for a missile to pass from side to side through the centrum of a vertebra without causing any symptoms of injury to the spinal cord. In the case of a double non-fatal hæmothorax, this is the path usually taken by the projectile concerned when it crosses in the upper two-thirds of the chest.

Treatment.

An intrathoracic wound of the duct is beyond the present skill of surgery for its repair. Case 1 shows that the fistula may close spontaneously in a few days. Increase of intrapleural pressure probably has some value in stopping the leak, for the chyle in the duct does not exert a high pressure, and therefore the volume of the effusion should be lessened by aspiration only when it is causing distress to the patient.

It is desirable that the prone position should be maintained in order to keep clots in contact with the apex of the chest. Fats in the food will increase the flow of chyle, but they will also help to give substance to any clot that may form. Whatever decision may be taken with regard to giving or withholding fats from the dietary, it is at any rate certain that they do not reach the patient's tissues so long as there is a complete leak from the duct, and therefore the sugars in the food must be increased in the attempt to maintain nutrition.

Case 2 was an example of a complete leak. Although the pleural cavity was infected, the patient showed a subnormal temperature that was below the limit of the thermometer, 95·4° F., every morning on the last eight days of his life, while it was continually subnormal on the last three days before that on which he died. His body wasted away with extraordinary rapidity. He did not suffer from the hunger or from the intense thirst that has been described by other observers as being so conspicuous in cervical cases, where the patient survived with a leak for a longer period. Very notable in this case were the huge masses of curdy yellow clot that progressively filled the pleural cavity as the fluid part of the effusion was daily drained away. These formed so large a deposit as to give the impression that had the effusion been sterile, and had the patient survived owing to a spontaneous closure of the fistula, it would have become necessary later to open the thorax and remove the clot in order to give the lung a chance of expanding.

We are indebted to the various medical officers concerned for their kind permission to publish these clinical histories of cases that were directly under their care.

CASE 1.—Sergeant P. August 8th, 1916: Wounded by shrapnel ball, which entered the chest immediately above the outer third of the right clavicle and lodged under the skin at the very apex of the left axilla near the posterior axillary fold. No hæmoptysis. No vomiting or difficulty with swallowing. Eighteen hours after this injury the patient walked a mile, and there was no suggestion of any damage to the spinal cord, though the right brachial plexus was slightly injured.

Fourth day: Subcutaneous emphysema of left side. Signs of small left effusion. Sixth day: Patient was sweating, cyanotic, and distressed; temperature swinging between 99° and 100° F. The effusion in the left chest had increased rapidly in the last two days, and in consequence of this accumulation the medical officer in charge suspected sepsis. Seventh day: Chest explored. A pink, opaque, creamy fluid was obtained, the character of which led to its being regarded on naked-eye evidence as undoubtedly purulent. Rib resection was at once performed. Much blood clot and a large quantity of apparently purulent fluid, estimated at about 80 ounces, were removed. Meantime the microscope had shown the exploration sample to consist only of blood and chyle, which separated on standing into a clean deposit of red cells below an opaque, creamy yellow fluid. Cultures subsequently proved this fluid to be completely sterile.

Eighth day: The resection wound was now completely closed by the surgeon in the hope that infection had not been introduced. Eleventh day: Physical signs of a large pneumothorax with complete collapse of left lung. Explored at left base; purulent fluid containing streptococci and a Gram-positive diphtheroid was found. The chest was opened again, air-tight drainage with a collecting flask being at first employed. The pleural fluid received in this flask was now simply purulent, and the leakage of chyle had completely ceased. The drainage at first was not satisfactorily arranged and the lung failed to expand well. Thirtieth day: Transferred to England. Still a very large empyema cavity, but patient was in good condition and had not lost flesh despite the heavy secondary infections that had been implanted on the originally sterile pleura.

The subsequent history was not fully ascertained, but ten weeks after the wound the patient was reported to be doing well.

[1] British Journal of Surgery, 1916, iv., 304.

CASE 2.—Sept. 15th, 1916: Wounded by fragment of shell which entered in the middle of the throat immediately below the thyroid cartilage. No exit wound. Fourth day: Admitted to base hospital. When seen a few hours later he was extremely ill and of a grey cyanotic tint. Temperature 97·4° F.; pulse 120 and weak. Heart displaced out to right nipple, and physical signs of complete pneumo-hæmothorax on the left side. From the general appearance of the patient at this early date, and from the absence of fever, it was thought to be most probable that the condition was that of a simple air leak and not of a gas pneumothorax caused by infection. The chest was aspirated on the same day by Captain Thatcher, R.A.M.C., who withdrew 90 ounces of grumous grey fluid, the appearance of which at first suggested that it might have come either from the stomach or from the thoracic duct. There was no offensive odour and litmus paper proved the fluid to be alkaline. After standing in a test-tube a small deposit of blood cells fell out as a red band at the bottom, leaving a greyish-yellow, opaque fluid above. Microscopically the fluid was found to be chyle, with an excessive number of polymorphonuclear cells in the deposit and a few Gram-positive bacilli. Its appearance on first withdrawal and before the separation of the red cells by standing was very like that of an ordinary empyema fluid, though there was just enough difference in tint to raise a suspicion, in view of the experience from the preceding case, of its having been derived from some abnormal source.

Fifth day: Bacteriological culture from the fluid discovered a streptococcus as well as *B. perfringens*. The patient was still very cyanosed and another 40 ounces of fluid similar to that of the preceding day were removed by aspiration. In the evening part of a rib was resected. More of the same fluid was found and the surgeon met with a yellow clotted mass in the pleural cavity which he thought to be prolapsed omentum and hastily replaced. Actually this mass was clotted chyle, which ought to have been removed.

Eighth day: Patient said that he felt worse. He was wasting with great rapidity and looked marasmic rather than septic. Pulse very feeble, 104; extremities cold, and temperature remaining deeply subnormal, below 95·4°. There was a slight cyanotic flush on his cheeks. The patient's bed was almost soaked in chyle, which continued to pour abundantly from the drainage-tube in his left side in the intervals when it was not blocked by yellow masses of clot that had a slightly rancid but otherwise inoffensive smell. He was drinking freely but without notable thirst, and had no appetite, though taking sugar and bananas fairly well. There had been no difficulty in swallowing at any time, and there was no hæmoptysis after the first day.

Ninth day: Heart still displaced to the right nipple, and still some cyanosis, while there was now a considerable amount of purulent sputum. In the hope of relieving the cardiac embarrassment a large drainage-tube was used with a big rubber flap which was cemented on to the chest wall by a solution of dental rubber dissolved in chloroform. This gave an air-tight junction and suction was then applied by means of an automatic aspirating bottle, the drainage products being collected in an intermediate receiving flask. This saved the patient from the exhaustion which had been caused by the need for frequent redressing when the chyle was allowed to leak out freely into the bed, and a large quantity of fluid was collected within the next 24 hours. But the apparatus failed to expand the lung because the tube was continually being blocked by masses of coagulated chyle.

Eleventh day: Patient had steadily been growing weaker and he died quietly. On this last day the temperature, which for the three preceding days had been below 95·4°, rose to 97°.

The autopsy showed as follows. Entry wound: A small healed scar in the neck to the right of the middle line just below the level of the cricoid. Beneath this lay a small collection of pus which had caused superficial necrosis of several of the cartilaginous rings of the trachea. The missile had entered the trachea and passed out from it again through a wound on the left side a little lower down. Both of the wounds were septic but practically closed.

The track then ran behind the main vessels entering the neck, and perforated the pleural sac about 1½ inches from its apex. The small piece of shell was found loose in the pleural sac, a position which it had reached after passing posteriorly through the upper lobe of the left lung and tearing a track along the upper surface of the lower lobe. The wound of the thoracic duct could not be found, but the track of the missile proved that this wound must have been in some position near the apex of the thorax that was surgically inaccessible.

The pleural cavity was filled with great masses of sour-smelling clot that resembled buttery yellow curds, and were very light to handle. The clots contained innumerable large cavities, spaced like those of a Gruyère cheese, each of which held inoffensive gas and a little fluid smelling of butyric acid. There was no appearance of pus to be found, nor any unpleasant odour suggesting the ordinary proteolytic products of a gas bacillus infection.

The left lung was completely collapsed and showed the wound track described above. It had not re-expanded at all after rib resection, presumably because the drainage had been interfered with by the accumulated masses of clot. The heart still remained in a position of extreme displacement to the right; there was no pericarditis. Bronchitis was evident in the right lung, but there were no areas of collapse.

Inoffensive gas (hydrogen and carbon dioxide) and simple organic acids are the ordinary products of the growth of pure *B. perfringens* on carbohydrates. No satisfactory analysis has yet been made by pathological chemists to show whether *B. perfringens* can effect the decomposition of fats, so that we are perforce content to record the changes observed in this clotted chyle without attempting any further explanation of them.

DONATIONS AND BEQUESTS.—By the will of the late Miss Emily H. Mortimer the Royal Isle of Wight Infirmary at Ryde and the Royal National Hospital for Consumption, Ventnor, will each receive £1000.—The late Mr. W. H. Sidley, whose estate has been valued at £16,000, left such sum as may be necessary for the endowment of a bed in the General Hospital, Birmingham, and the residue of his estate in equal shares to the Queen's Hospital and the General Hospital, Birmingham.

THE MENACE OF MORPHINE TO CHINA.[1]

BY WU LIEN-TEH (G. L. TUCK), M.D. CANTAB.,
PRESIDENT OF THE CHINESE NATIONAL MEDICAL ASSOCIATION.

THE year 1917 will be historic as the one in which opium, the curse of China for 75 years, will be officially and finally banished from the country, for in this year the ten-year agreement made between Great Britain and China regarding its importation into China, including the last two seaports of Shanghai and Canton, will come to an end, so that even in the British Settlement of Shanghai the remaining opium shop will be closed by the month of March. The whole nation will rejoice at this happy termination of an awful vice, which once looked as if it might exterminate the Chinese race. That the drug is scarce may be ascertained by the fact that the present price in Canton is at least $15 per tael, with a tendency to rise. Except for some smuggling from Turkestan and Russia by way of Siberia very little opium will in future find its way into China, though the Government and Customs authorities will still have to exercise, in dealing with this enormously paying business, the greatest vigilance over unscrupulous people.

Morphine Statistics: British and Japanese Traders in Morphine.

I am afraid we cannot be so sanguine with regard to morphine, for up to the end of last year all statistics point to increased importation into China. The supply of morphine comes mainly from two firms in Edinburgh and one firm in London. The following table shows the declared exports of morphine from Great Britain alone:—

1912	.....	276,572 ounces,	equal in weight	to	7¼ tons.
1913	.....	406,154 ,,	,,	,,	11¼ ,,
1914	.....	504,020 ,,	,,	,,	14 ,,

It is estimated that the exports in the years 1915 and 1916 are at least 600,000 ounces for each year, equal to over 16 tons. Moreover, the normal importation of opium into Japan for medicinal purposes is only 10 chests a year, but the importation of morphine into that country in 1911 was 1¼ tons; in 1914 this had risen to 12 tons—that is, 1 ton a month. There is a large firm in Japan which acts as agent for the manufacturing firm in London. In 1913 alone this agent in Japan imported 2¼ tons of morphine by *registered post* via Siberia. The two other British firms exported 2 tons by the same method, and 1¼ tons came from Germany, making a total of 6¼ tons in 1913. So far it has been ascertained that neither Japan nor Germany has got the necessary plant to manufacture morphine on any large scale, and the alkaloid has come mostly from firms in Great Britain. Once arrived in Japan the morphine is usually made up into small packets or placed into small bottles, labelled in different ways—e.g., morphine, "white powder," "soothing stuff," "dreamland elixir," &c., and exported openly or smuggled secretly into China by way of Dalny, Antung, and Formosa. Almost every Japanese drug dealer or pedlar in Manchuria sells it in one form or another, and does so with impunity, because no Japanese can be arrested without complaint being first lodged at the Consulate. From these Japanese agents and sub-agents the drug may be passed on to disreputable Chinese who frequent the coolie depôts and inject a solution, usually very dirty, with a hypodermic syringe which may be made with glass, metal, or even bamboo. Rigorous imprisonment for two years is a common sentence for Chinese found with morphine in their possession, but the principal culprits often escape punishment.

The morphine habit was first brought into China by returned Swatow emigrants from Singapore and spread to other parts of Fukien. During my five years residence in Manchuria I have seen terrible havoc wrought upon the population by this drug. More than half of our regular jail-birds there show needle signs over their bodies, professional beggars found in the streets of Harbin, Kirin, Changchun, and Tsitsihar are victims of the habit, and thousands of poor people die in the large cities during the winter months, partly from cold but principally from inability to work on account of their morphine habits. From all sources I learn that the evil is spreading rapidly, and it is worse than opium

[1] A paper read before the Joint Medical Conference, Canton, January, 1917.

smoking. Enormous profits are made by the dealers in this illicit trade. The average wholesale price of morphine hydrochlorate in London is 10*s.* 5*d.* per ounce, but the Japanese pedlars sell it in China for £4 10*s.* to £5.

The profits made on 6½ tons by the dealers in China in 1913 amounted to £840,000. Unless strong action is taken by our profession, as was done by us in the case of opium, the morphine evil will assuredly spread farther and render futile all our efforts in the direction of opium eradication. The question is, "What are we to do?"

The Hague Conventions with Regard to Opium, Morphine, Cocaine, and Allied Drugs.

Three Opium Conferences have already been held at the Hague—in 1911–12, 1913, and 1914. At the first a Convention was drawn up in which all the participating Powers (Great Britain, United States, China, France, Germany, Italy, Japan, the Netherlands, Persia, Portugal, Russia, and Siam) agreed to help one another mutually in restricting the evil effects of opium, morphine, cocaine, and allied drugs. At the Second Conference 44 out of 46 Powers of the world had already agreed to append their signatures to the Convention, and at the Third Conference the United States, the Netherlands, and China deposited their ratifications so as to act forthwith upon the articles of the Convention. Although the representatives of Great Britain were instructed at the Second Conference to declare on behalf of their Government their readiness to ratify, the matter has so far been delayed. In the meantime the war has put a stop to many things, but morphine continues to find its way into China. Two articles in the Convention signed on Jan. 23rd, 1912, deal particularly with morphine and allied alkaloids. These are:—

Art. 9.—The Contracting Powers will enact pharmacy laws and regulations so as to limit the manufacture, sale, and use of morphine, cocaine, and their respective salts to medical and legitimate uses only, unless such laws already exist. They will coöperate among themselves in order to prevent the use of these drugs for any other purpose.

Art. 14.—The Contracting Powers will apply the laws and regulations for the manufacture, import, sale, or export of morphine, cocaine, and their respective salts to (*a*) medicinal opium, (*b*) to all preparations (official and non-official, including the so-called anti-opium remedies) containing more than 0·2 per cent. of morphine or more than 0·1 per cent. of cocaine, (*c*) to heroin, its salts and preparations, containing more than 0·1 per cent. of heroin, (*d*) to every new derivative of morphine, cocaine, or their respective salts, or to any alkaloid of opium which, as the result of scientific research, shall be generally recognised as giving rise to analogous abuse or producing the same injurious effects.

If these articles had been put into operation, along with the rest of the machinery provided in the Convention, a great deal would have been done towards controlling the production and distribution of drugs of addiction throughout the world and restricting them to use for medicinal and legitimate purposes only. As it was, the war came on, and both Great Britain and France were obliged to introduce severe laws against the illicit use of morphine and cocaine by the armies and inhabitants of the warring regions. A recent Government Order announces the entire prohibition of the importation of opium into Great Britain except with the sanction of the Government. It is to be hoped that this will result in the limited manufacture of morphine so that as little as possible of this harmful alkaloid may find its way out of the country.

If proper pharmacy laws are enacted in China the problem of morphine eradication will be really an easy matter. Unlike opium, it has never been declared as an article of commerce, and our Government has always regarded it as a prohibited drug. Once Great Britain refuses to sanction its export, except directly to friendly Governments or legally qualified agencies, the question of smuggling will not be such a serious affair.

The Procedure Recommended.

The Customs laws regarding the importation of morphine and hypodermic needles into China are somewhat crude and inflict much hardship upon qualified medical men and apothecaries. One meets, for instance, with the following Customs Regulation (No. 693):—

On and after the 1st Dec., 1910, the manufacture in China by Chinese and foreigners of cocaine, morphia, and of syringes, needles, and such-like instruments for its use, is absolutely prohibited; and the importation of the same into China by Chinese and foreigners is likewise prohibited—except in the case of *duly qualified foreign medical practitioners*, foreign chemists and druggists, civil hospitals established by Government in any province, military and naval surgeons, and medical colleges of any kind complying with the following conditions, &c.

If taken literally—and it is often thus done—a Chinese medical man, however well qualified from Europe, America, or Japan, will be unable to use morphine or cocaine for the most humane purposes. Again, a hypodermic syringe is regarded by the Customs as an instrument solely for the illegal use of such drugs, and no Chinese medical man is able to procure it for the injection of emetine, pituitrin, or any of the new drugs. As matters remain at present, the culprits escape, for they can evade the laws by not declaring properly, whilst bona-fide practitioners and qualified apothecaries have to undergo all sorts of difficulties in this connexion.

I would suggest that this Conference pass some resolutions—

(1) Drawing the attention of the Government to the menace of morphine in China and the importance of taking immediate steps against its illegal use by cutting off the supply from the source.

(2) Asking the Government to enact without delay proper pharmacy laws to regulate the position of dispensers and pharmacists in charge of drug shops, the sale of morphine, cocaine, and other deleterious drugs and poisonous chemicals.

The articles of the Hague Opium Convention have amply paved the way for such laws. If requested, our two associations would depute members to render the necessary assistance in drafting the laws. The establishment of a Central Medical Council would facilitate matters immensely.

THE EXPERIMENTAL PRODUCTION OF TUBERCULOUS PERITONITIS IN GUINEA-PIGS PREVIOUSLY EXPOSED TO X RAYS.

BY J. J. McGRATH, M.B. R.U.I., D.P.H.

(*From the Bacteriological Department, Guy's Hospital.*)

THE existence of acid-fast bacilli, other than *B. tuberculosis*, in pathological material frequently necessitates inoculation methods either to confirm or exclude a diagnosis of tuberculous infection. Unfortunately the general utility of such tests is often discounted by the length of time before a definite result can be recorded.

Experience has already impressed upon us the advisability of employing the guinea-pig for inoculation purposes, since the introduction of even a few tubercle bacilli into this animal is followed by a definite sequence of events terminating in death from general tuberculosis at some period near to, or remote from, the date of inoculation (according to number of bacilli injected, type of bacillus—i.e., human or bovine, virulence of strain, site of injection, and other factors), and varying from a few weeks to several months.

The deterrent effect of this time factor which operates so adversely against the universal employment of animal experiment in clinical laboratory diagnosis has stimulated research, having for its object the abbreviation of the "observation period," with hitherto but few tangible improvements on the methods of Villemin.

Recently Morton and Murphy,[1] during the course of observations on the behaviour of transplanted cancer in white mice, noted that repeated exposures to small doses of X rays destroyed the major part of the lymphoid system in these animals without causing any obvious injury to other tissues or exercising any deleterious effect upon the general health. Heineke[2] had already shown that the effect of X rays was first manifested by the destruction of the lymphocytes.

Subsequently Morton[3] found that the same changes occurred in the guinea-pig, and further that one massive dose of X rays produced in this animal the same effect as repeated exposures to small doses. Taking now as a starting-point the assumption that the lymphoid system forms the main defence against infection by *B. tuberculosis*, Morton first exposed his guinea-pig to a massive dose of X rays, then inoculated into the peritoneal cavity material containing the tubercle bacillus, and obtained a tuberculous peritonitis obvious to the naked eye, as well as microscopically, within 14 days.

The importance of these observations, if capable of corroboration, cannot well be over-estimated, and this preliminary note deals with my experiments in this direction.

Normal healthy guinea-pigs of from 200 to 250 grammes in weight were exposed on one occasion only for a period of

[1] Journ. Exper. Med., 1915, xxii., 204.
[2] Mitt. a.d. Grenzgeb. d. Med. u. Chir. 1905.
[3] Journ. Exper. Med., 1916, xxiv., 419.

10 minutes to X rays derived from a Coolidge tube, a current of 5 milliampères backing up a 12½ in. spark. A differential leucocyte count was made of 25 of these animals the day following exposure to the X rays and every second or third day subsequently until the animal died or was killed, in one instance as many as 15 days later. Of these 25 animals a fall took place in the percentage lymphocyte count in 11 only, in 2 it was unaltered, and in 12 it was actually increased. These observations are being repeated.

The guinea-pigs after exposure to the X rays were then inoculated intraperitoneally with sputum or other material rich in acid-fast bacilli, which had all the morphological and tinctorial characters of *B. tuberculosis*. In the early experiments the association of common pyogenic bacteria in the material injected led to several deaths from acute septicæmia due to streptococcus or *B. coli*, but this risk was subsequently overcome by treating with antiformin every specimen that was not microscopically "clean" before injecting it into the guinea-pig.

The results obtained fully confirm Morton's observations, as the six selected examples in Table I. show. From these results it may be assumed that, given inoculum rich in tubercle bacilli, the experimental animal may be destroyed within 14 days with tolerable certainty that macroscopical tuberculous lesions will be found post mortem.

TABLE I.

Material inoculated: Guinea-pigs A, B, C, D, E, 1·0 c.c. sputum crowded with *B. tuberculosis*; F, 1·0 c.c. urinary deposit (catheter specimen).

Guinea-pig.	Result of inoculation of X-rayed G.P.	Post-mortem lesions.	
		Naked eye.	Microscopical.
A	Killed after 16 days.	Spleen enlarged, no tubercles seen. Liver, no tubercles. Mesenteric glands everywhere enlarged, soft and caseous.	T.B. present.
B	Killed after 15 days.	Spleen enlarged, with tubercle present. Tubercles on liver. Mesenteric glands everywhere enlarged, soft, caseous, breaking down easily.	,,
C	Killed after 14 days.	Spleen much enlarged. Tubercles on liver. Mesenteric glands everywhere enlarged, soft and caseous.	,,
D	Killed after 13 days.	Spleen normal. Caseating nodules found on liver. Numerous soft caseating enlarged mesenteric glands.	,,
E	Killed after 11 days.	Tubercles on liver and spleen, latter much enlarged. Mesenteric glands everywhere enlarged, soft and caseous.	,,
F	Killed after 12 days.	Small tubercles on much-enlarged spleen. Mesenteric glands, several enlarged, soft, caseous, easily breaking down.	,,

One of the points elicited by Murphy[4] in his earlier experiments is summarised in the following statement:—

"If the lymphoid system of an adult animal be depleted by exposure to X rays, the animal loses its power of resistance to heterologous tissues, and transplanted tissues are thereby enabled to grow readily within its body."

My own observations on the guinea-pig tend to show that this lack of resistance extends not only to the strangers within the gates—the inoculated tubercle bacilli—but also to its relationship to the external world, and many failures at the commencement of the investigation are to be ascribed to this cause.

As examples may be cited guinea-pig 1, which died within 24 hours from acute *B. coli* peritonitis; the control animal, identical in weight and injected with a similar quantity of sputum, remained alive for three weeks before it succumbed to general tuberculosis. Guinea-pigs 8, 9, 10, 11, 12, 13, all inoculated with the same material, died within 48 hours of acute streptococcic septicæmia. Guinea-pigs 24, 25, 27, and 28 were found dead within a few days of inoculation, in the morning following particularly cold nights in February of this year, whilst similar sized animals in adjacent cages were unaffected.

The earliest date at which naked-eye manifestations can be obtained has not yet been determined exactly, but a number of early deaths followed the inoculation of sputum literally crowded with tubercle bacilli, when no lesions were observed and no tubercle bacilli could be demonstrated microscopically up to the end of five days. (Table II.)

[4] Journ. Exper. Med., 1914, xx., 397.

TABLE II.

Material inoculated: Sputum in each instance.

Guinea-pig.	Result of inoculation of X-rayed G.P.	Post-mortem lesions.		Control.*
		Naked eye.	Microscopical.	
G	Died after 24 hours.	Good deal of fluid in peritoneal cavity.	Films from fluid and heart's blood showed the presence of *B. coli*. No T.B. could be detected.	Died after 21 days.
H	Died 4 days after inoculation.	Nil found.	No T.B. could be detected.	—
J	Died in 5 days.	No lesions found. Suspected to have died as a result of inoculation of antiformin.	No T.B. could be detected.	Died after 19 days.

* *Controls: Post-mortem lesions.*—Naked eye: In both control animals tubercular lesions found in spleen, liver, and mesenteric glands. Microscopical: Films showed T.B., numerous in guinea-pig G.

The most striking examples of early generalisation of *B. tuberculosis* in these X-rayed guinea-pigs are given in Table III. The value of the method must, however, be estimated by a standard of reliability—that is to say, it is not sufficient for the inoculation of material crowded with acid-fast bacilli to give a positive result at an early date; it must be capable of giving evidence of the presence of *B. tuberculosis* even when the material inoculated fails to show the micro-organism after prolonged microscopical examination. Two examples will suffice upon this point. (Table IV.)

TABLE III.

Material inoculated: In each instance 1·0 c.c. sputum crowded with *B. tuberculosis*.

Guinea-pig.	Result of inoculation of X rayed G.P.	Post-mortem lesions.	
		Naked eye.	Microscopical.
K	Died after 7 days.	Pin-point tubercles on spleen and liver. Spleen much enlarged. Mesenteric glands enlarged, soft, and caseous.	T.B. present.
L	,,	Pin-point tubercles found on liver. Numerous enlarged soft caseating glands which easily broke down.	,,
M	,,	Spleen enlarged. Numerous enlarged soft caseating mesenteric glands found.	,,
N	,,	Spleen enlarged. Mesenteric glands everywhere enlarged, soft, and caseating.	,,
O*	,,	Spleen somewhat enlarged. Numerous mesenteric glands enlarged, soft, and readily breaking down.	,,

* X-rayed three days before inoculation.

TABLE IV.

Material inoculated: Guinea-pig P, fæces; Q, catheter specimen of urine.

Guinea-pig.	Clinical diagnosis.	Result of inoculation of X-rayed G.P.	Post-mortem lesions.	
			Naked eye.	Microscopical
P*	Tubercular disease of intestine, ulceration.	Died after 8 days.	Spleen and liver not enlarged. Coils of intestine matted together. Small abscess found between coils of large gut. Mesenteric glands everywhere enlarged and soft.	T.B. present.
Q	Tubercular disease of kidney.	Killed after 12 days.	Tubercle found on spleen. Numerous mesenteric glands enlarged, soft, and caseous. No tubercle on liver.	,,

* X-rayed 3 days before inoculation.

In the fæcal material employed to inoculate guinea-pig P very prolonged search of the centrifugalised deposit after antiform treatment resulted in the detection of one small bunch of acid-fast bacilli; whilst careful search by several observers of the centrifugalised urinary deposit, subsequently injected into guinea-pig Q, failed to show any acid-fast bacilli whatever.

OPERATION FOR LOOSE SEMILUNAR CARTILAGE.

BY R. P. ROWLANDS, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO GUY'S HOSPITAL.

A GREAT many operations have been performed for loose cartilage during the war, but the recovery of perfect function and fitness for active service has been slow in many cases. Those who supervise the after-treatment by massage, movements, and exercises tell me that they are depressed by the long duration of convalescence and disappointed with the ultimate results in some cases. These facts should lead us to consider whether sufficient care is taken in (1) the selection of cases suitable for operation; (2) the technique of the operation; and (3) the after-treatment.

I. *The Selection of Cases Suitable for Operation.*

It is clearly of the greatest importance to be sure of the diagnosis. Therefore the symptoms, signs, and diagnosis will be briefly discussed here.

Symptoms.—The history of the original and subsequent injuries is of the greatest importance, for the detachment of a semilunar cartilage is nearly always due to *indirect violence* such as a sudden twist of the leg. The internal cartilage is commonly displaced by a sudden outward rotation with abduction of the leg at the knee-joint. Occasionally it is due to extreme flexion of the knee and the sudden attempt to get up. Generally there is a severe pain and often an audible click at the moment of displacement. In many cases the patient feels the cartilage go both out and in. Often the patient has to be carried home or walks painfully on tiptoe, quite unable to fully extend the knee. As a rule, effusion occurs in the first attack. Recurrent displacements are often brought on by more trifling injuries, and later still the cartilage may be displaced by slight movements, such as turning over in bed.

Signs.—When the knee is examined soon after a displacement there may be distinct tenderness over the internal cartilage, and unless the latter has gone back into place the knee cannot be fully extended, and any attempt to do this causes great pain and a tight feeling behind the knee. As a rule, more or less effusion follows for a few days or weeks.

Diagnosis.—It is very important to take pains to exclude other conditions which may simulate loose cartilage, especially osteo-arthritis. An X ray examination often reveals changes in the articular surfaces and in the bones around. There is creaking in the joint, and other joints are commonly affected. Early tuberculosis, especially starting in the synovial membrane near the internal cartilage, is very difficult to distinguish, and radiography does not often help, but the peculiar pulpy character of the swelling with limitation of flexion, the general condition, and the history, are valuable aids in the diagnosis. Laceration of the internal lateral ligament, or partial detachment of it from the femur, may occur at the same time as displacement of the internal semilunar cartilage, but with this condition alone there is distinct local tenderness over the internal surface of the internal condyle of the femur, and sometimes there is an effusion of blood at this spot. In some cases the X ray examination reveals an exostosis near the knee-joint either of the femur or tibia. The slipping of a tendon over one of these may cause symptoms simulating those of a loose cartilage. Also a sprain of the tendons inserted on the inner side of the tibia high up—the sartorius, semitendinosus, or gracilis—may be mistaken for loose cartilage, but the tenderness, creaking, and swelling are lower. Radiography may indicate a new growth near the joint, especially in the centre of the head of the tibia or lower end of the femur. Such a growth may cause much pain and recurrent effusion into the knee-joint as a result of slight strains. The same method of examination may show one or more loose bodies in the joint, generally between the condyles of the femur or in the subcrural pouch of synovial membrane. A sesamoid bone near the gastrocnemius origin has often been mistaken for a loose body. Certain loose bodies such as detached fringes or pieces of articular or semilunar cartilage do not throw a shadow on the screen. In some cases an X ray examination reveals fracture or even detachment of the spine of the tibia. As a rule, this injury is the result of extreme violence. Enlargement of the ligamenta alaria sometimes simulates loose cartilage, and so may pendulous synovial fringes in other parts of the joint. These, unfortunately, do not show with the X rays. Detachment of the *external* semilunar cartilage is far less common, and when it does occur it is liable to be mistaken either for slipping popliteal tendon or internal semilunar. I have found it extraordinarily *movable as a whole*, and especially so in children over ten years who give no very convincing history of a definite injury. One boy could put the cartilage out and in at will during flexion and extension. A very loud click was heard at each movement, and the leg jerked laterally, while a swelling came and went away at the outer side of the patellar ligament.

Slipping of the popliteus tendon usually causes creaking and effusion further back on the outer side of the knee. Many youths, and especially young girls, develop recurrent effusion with insecurity of the knees as a result of prolonged exercise, but there is no history of locking or sudden clicking with agonising pain.

So many things may simulate loose semilumar cartilage that it is not always easy to be quite sure of it; therefore great care must be taken in gathering an accurate history, in making all necessary examinations, and in considering all the possible pitfalls. In many cases accurate diagnosis is impossible, but if the symptoms and disabilities are severe and recurrent, and due care has been taken to exclude the conditions which are not likely to be benefited by an operation, it is wise to advise exploration. As a rule, this soon reveals a removable cause.

Indications for and Against Operation.

1. It is rarely wise to operate after the first detachment, for recovery without operation is possible in these cases, unless the cartilage is actually out of place and cannot be reduced even under an anæsthetic.
2. When an anæsthetic is necessary to replace the cartilage an operation by a skilful surgeon with due care does not add materially to the risk of the patient. But under opposite or doubtful conditions it is clearly better to treat the case conservatively after the replacement. The best evidences of the persistence of the displacement are locking and inability to fully extend the knee, for when the cartilage lies between the prominent part of the condyle of the femur and the articular surface of the tibia, it is practically impossible to extend the knee to the full extent.
3. When the cartilage only causes slight symptoms but no actual disability for work or necessary exercise it is not advisable to operate; but
4. If frequent displacement interferes with the capacity of earning a livelihood or of taking necessary exercise an operation should be recommended.
5. It should be urged for recurrent displacement when the patient is liable to go to risky places where a sudden detachment may land him and perhaps his fellow workers in danger.
6. For soldiers liable to active service and coming under Groups 4 and 5 an operation is necessary. The same treatment seems to me to be advisable in them for severe first displacements calling for an anæsthetic for their replacement. It is clear that under the trying conditions of active service recurrence is very liable to take place, and much time is wasted by treating such cases too conservatively. On the other hand, slight displacements causing only transient symptoms are best treated conservatively and the patient kept on home service or garrison duty.

II. *Operation for Loose Internal Semilunar Cartilage.*

It is probable that most of the imperfect results of operation are due to errors of technique, and particularly to failure to take full advantage of a tourniquet. By using a tourniquet and making the operation bloodless the operation is made very much easier and safer, for the surgeon can see quickly what is wrong and deal with it in a few minutes. There is no need to use any sponges or to introduce anything into the knee except sterile instruments. Manipulations and undue irritation by frequent sponging, long exposure, and, above all, the escape of blood into the knee-joint are avoided. All these tend to cause synovitis and even infection, and therefore delay the after-treatment by massage, movement, and exercises. Many surgeons do not use a tourniquet at all for this operation, being afraid of bleeding into the joint after the operation. Many others remove the tourniquet towards the end of the operation in order to secure the divided blood-vessels. This is entirely unnecessary, and the tourniquet should not be removed until the

wound has been accurately sewn up and the bandages firmly applied over a massive dressing. Under these circumstances there is no reason why a patient should be laid up any longer after an operation for loose cartilarge than after an ordinary slipping of the cartilage—in fact, the removal of the cartilage should hasten the recovery of function.

Most of the disabilities following the operation are due to the effusion of blood or fluid in the knee as a result of (*a*) faulty technique, (*b*) various degrees of infection, and (*c*) unnatural restraint imposed upon the knee after the operation. Whenever possible the patient is made to rest his knee for two or three days before the operation, so as to lessen the effusion and congestion of the synovial membrane. The skin is carefully prepared. It is shaved, if necessary, from the middle third of the thigh to the middle third of the leg, then washed with ether, painted with tincture of iodine, and a sterile pad applied. When the patient is under the anæsthetic the leg is held up for several minutes to empty it of blood as far as possible, and then a flat rubber tourniquet is applied very tightly around the middle of the thigh. The knee is nearly semi-flexed over pillows or over the end of the table, and sterile towels are carefully arranged and secured to the thigh and leg. A vertical incision[1] 2½ inches long is made over the interval between the tibia and femur, one inch internal to the ligamentum patellæ. The wound extends downwards half an inch below the upper border of the tibia. Sterile gauze pads are clipped to the edges of the wound before the knee-joint is opened. These leave no skin exposed. The capsule is opened freely and generally some fluid escapes. By retracting the edges of the capsule a good view is obtained of the anterior part of the internal semilunar cartilage, and any abnormality of this part can be seen at once. In many cases a tongue-shaped piece is semi-detached and turned inwards. In others the whole of the anterior part is loose. In others the two ends are the only parts attached, the middle portion often lying in or towards the intercondyloid notch. In some cases the cartilage looks normal, but proves unnaturally movable backwards and forwards as a whole. In a few cases the front end seems normal, but on drawing the cartilage forwards and flexing the knee a detached piece can be seen turning in from the posterior part of it. While the assistant retracts the edges of the wound the surgeon detaches the front end of the cartilage from the tibia with the knife and draws it forwards and inwards with a Mayo-Ochsner forceps, while he gradually separates the middle and posterior parts from the tibia and capsule of the joint. The separation of the posterior part is made easier by further flexion of the knee, and especially by the use of a strong blunt-ended tenotome. Nearly the whole cartilage is removed, for incomplete removal is a frequent cause of recurrence of symptoms. Unless the cartilage is at fault some other cause of the symptoms must be sought, and, if necessary, the wound prolonged upwards. In many cases the tags of the internal alar ligament are enlarged and œdematous. Sometimes they are very large, white, and hard from frequent injury. These should be removed. In some cases the anterior crucial ligament will be found to be partly detached from the tibia, with its free end frayed, obviously calling for removal. In others a fracture with detachment of part or the whole of the spine of the tibia is seen. In a few one or more loose bodies will be seen in the inter-condyloid notch or perhaps be squeezed from the subcrureal pouch by external manipulation. Exceptionally a fracture of the articular cartilage of the femur will be seen, especially on the front. A tongue-shaped piece of the articular cartilage may flap and display the bony surface of the femur. It can be replaced so that only a linear fracture is seen, but the movements of the patella dislodge it again during active exercise. The whole flap should be removed and the edges of the gap smoothed with a sharp knife. The knee is straightened and the capsule is accurately sewn with continuous fine sterile catgut, and the skin with a continuous suture of linen thread. A sterile pad is placed on the wound and secured by a sterile gauze roll. Then a large pad of Gamgee tissue or cotton-wool is applied all around the lower third of the thigh, the knee, and the upper third of the leg, and this is bandaged firmly but not very tightly. Another thick layer of cotton-wool is applied and very firmly bandaged, taking care to leave the upper edge a little looser than the rest, in order to avoid discomfort and swelling of the knee and leg. For the same reason a cuff of wool extends both above and below the tight bandages. Then the tourniquet is removed. No splint is applied, but the knee is slightly flexed over a soft small pillow and the limb is raised on a wedge pillow.

[1] Curved incisions trespassing on the important internal lateral ligament are to be condemned, and so are low incisions approaching the cartilage from below and giving no adequate view of the interior of the joint.

III. *The After-Treatment.*

As a rule there is very little pain and rarely any that is not controlled by doses of aspirin, gr. x. Every day from the beginning the knee is moved a little more. A hand is placed under the knee and the limb thus very gradually flexed. Then the heel is lifted up and a hand is placed on the front of the knee to straighten the latter. No pain need be elicited if this method is adopted early and gently enough. At the end of three or four days the outer bandage and layer of cotton-wool are removed and, if necessary, the inner bandage is slackened a little, but the sterile dressings are not disturbed until the end of a week when the stitches are removed. Then the patient is allowed up on a wheel chair with the leg slightly flexed. On the tenth day he is allowed to walk about somewhat stiff-kneed, taking care to keep the diseased leg always in front of the healthy one, and to put the weight chiefly on the heel. This prevents the knee giving way. From the beginning the extensors of the knees are gently massaged, and the patient is encouraged to use these muscles and to move the knee a little more every day. The patella is moved sideways and up and down upon the femur every day. All passive movements are gentle and steady, and never sudden or jerky. At the end of a week flexion to a right angle is generally easy and comfortable. Massage of the knee-joint is not commenced before 12 days, when the wound is firmly healed. Exercises against resistance are very valuable in developing the muscles. Radiant heat and cataphoresis are often desirable, and a crêpe bandage around the knee *only* is useful for about a month. While the application of splints with delay in active movements are extremely detrimental, violent passive movements commonly cause effusion, pain, weakness, loss of confidence, and delay in recovery. Similarly, prolonged standing and fatigue from any form of active exercise in the early days delay recovery. All movements should be gentle, all exercise short of fatigue. With due care the patient is generally walking about fairly well at the end of a fortnight. Movements and power are almost perfect within a month or six weeks.

THREE CASES OF SEPTIC INFECTION DUE TO OTITIS MEDIA.

BY W. WILSON, M.D., B.Sc.,
CAPTAIN, R.A.M.C.;
AND
J. W. BARRETT, C.M.G., M.D., M.S. MELB., F.R.C.S. ENG.,
TEMP. LIEUTENANT-COLONEL; CONSULTING AURIST, B.F.

THE three cases referred to in these notes made their appearance in a military hospital at about the same time. As there is scarcely a problem connected with septic infection following on aural disease which was not involved in their management, and as the results in the second and third cases were most gratifying, we have thought it worth while to place a summary of the facts on record.

CASE 1. *Otitis media: broncho-pneumonia; abscess of neck; cerebellar abscess; death.*—Private, aged 20, admitted to hospital with profuse otorrhœa on right side. The ear had discharged for a long time previously and apparently had not been treated. Small perforation of membrane and some tenderness behind mastoid process. Temperature normal, pulse 64 to 74, and respirations 16 to 18. Two days after admission temperature suddenly rose to 104·4°, pulse to 86, respirations to 20 but no rigor. The mastoid process was immediately opened up; some granulation tissue found in antrum and one small pocket of pus in mastoid process.

Shortly afterwards patient developed broncho-pneumonia, apparently streptococcal in origin, and temperature range rose daily to 102° for about 10 days, when it became practically normal. General condition fairly good, but he did not progress; no definite symptoms referable to head. Examination of eyes, however, on eighteenth day after admission showed optic neuritis with hæmorrhages on opposite (left) side. The following day blood count showed very slight leucocytosis.

Exploratory operation; mastoid wound was enlarged upwards and backwards and a large extradural cerebellar abscess evacuated. Lumbar puncture gave no indication of any abnormality of cerebro-spinal fluid. Condition remained somewhat unsatisfactory, with temperature rising to 102° until forty-third day, when optic neuritis was found to have definitely increased. Focal symptoms completely absent. In view, however, of unsatisfactory general condition the bone above and behind mastoid was removed, the dura exposed, and both cerebellum and middle lobe explored with negative results.

On the fiftieth day a deep-seated abscess in back of neck on both sides was evacuated. It was apparently unconnected with mastoid, at all events no gross connexion was visible. The pus was streptococcal. On fifty-second day internal jugular vein was exposed and tied, but patient died of exhaustion three days later. No vomiting and cerebral symptoms absent from beginning to end.

The post-mortem report was as follows: Lungs congested, less resilient than normal. Heart fatty with a little fluid in pericardial sac. Kidneys congested. Brain: dura slightly adherent over vertex. Cerebral vessels turgid. Cloudy yellow fluid issued from beneath tentorium. On raising tentorium patches of lymph were observable on right half of cerebellum. Whole of under surface of cerebellum and pons was coated with layer of lymph. There was an abscess cavity in right half of cerebellum in antero-inferior portion. It was irregular in shape and approximately 2 × 1½ cm. in size.

This case was noteworthy because there were no symptoms of cerebral complication. The guarded prognosis given throughout was based on the continuance of the left optic neuritis. The existence of optic neuritis was the more remarkable, as from first to last there was no suggestion of raised intracranial pressure.

CASE 2. *Otitis media; mania; infarcts in lungs and intestines; gluteal abscess; recovery.*—Private, aged 28, admitted into hospital with profuse otorrhœa on right side. History of long-standing ear disease; apparently no treatment. Temperature on admission 100·2° F.; pulse 72. Small perforation of membrane and some slight tenderness over mastoid region. Two days after admission temperature suddenly rose to 104·8° and pulse to 96, but no rigor. He became semi-maniacal and had to be put under restraint. A swelling appeared below mastoid process, and operation was performed on sixth day after admission. Whole of mastoid process was riddled with collections of pus, but lateral sinus apparently normal. On fourth day after admission white blood count was 15,300. After operation mental condition improved, but temperature oscillated between 103° and 98·8° until eighth day, when he developed in rapid succession diarrhœa with blood-stained mucous discharge showing *Bacillus coli*, pulmonary infarction with hæmoptysis, and a large gluteal abscess extending down to sacro-sciatic notch. Pulse rose to 150 and temperature remained irregular. A blood culture at this stage showed streptococci. There was no optic neuritis, but there were patches in his eye of old choroido-retinitis. On fifteenth day jugular vein was ligatured in neck and lateral sinus exposed and obliterated; abscess in gluteal region drained. The exposed dura mater was explored with negative results. Fifteen ounces of pus were obtained from gluteal wound. From this point recovery was steady and only interrupted by suppuration along track of jugular vein which gave no serious trouble.

The recovery of the man is remarkable and is really an indication of the possibilities of successfully combating gross septic infection.

CASE 3. *Otitis media; extensive mastoid involvement; septicæmia; recovery.*—Rifleman, aged 25, admitted into hospital with profuse discharge from right ear. History of long-standing otorrhœa; apparently no treatment. On admission tenderness over mastoid region; temperature ranged between normal and 100° F.; pulse 104. Discharge very profuse. Usual mastoid operation at once performed; greater part of mastoid process was removed by reason of extensive infiltration with pus. Lateral sinus appeared normal, but there was a small sinus leading down to cerebellar dura mater which was curetted. The whole of the suppurating bone could not be removed for obvious anatomical reasons. On the fifth day after admission temperature rose to 105·6°, pulse to 140, respirations to 30. He sweated profusely and was seriously ill without definite localising symptoms. Temperature subsided somewhat, but condition not satisfactory. Blood count showed white blood corpuscles 13,100. On tenth day jugular vein was tied and lateral sinus traced backwards and obliterated by pressure in mastoid region; dura not opened. The patient was not relieved and developed stiffness in back of neck with muscular rigidity. Fluid obtained by lumbar puncture appeared normal. His condition remained unsatisfactory, temperature rising to 102°, when an abscess appeared along course of jugular vein, and on its evacuation symptoms came to an end; excellent and uneventful recovery. Cultures made from blood during course of disease showed streptococcal infection.

Reviewing these three cases it is difficult to assign a positive and specific value to ligature of the jugular vein, but the impression left in mind is that the operation was of definite service. The recovery of Case 2 is remarkable and illustrates so well the general rule that whilst septic infections in aural cases within the dura mater are too often fatal, recovery can be expected in many septic aural cases with the grossest lesions so long as the infection is outside the dura mater. It should be stated that antistreptococcal serums were freely employed in all three cases. The operative procedure throughout was effected, so far as the aural work was concerned, by Captain William Wilson, R.A.M.C. (T.C.), and so far as the general surgical procedure was concerned, by Captain S. W. Maslen Jones, R.A.M.C. The post-mortem and pathological examinations were made by Captain E. C. Myott, R.A.M.C.

LIGATURE OF COMMON CAROTID ARTERY.

NOTES ON THREE CASES AT A CASUALTY CLEARING STATION.

BY J. J. M. SHAW, M.D. EDIN.,
CAPTAIN, R.A.M.C., S.R.

IN those cases of injury to the large vessels of the neck which escape death upon the field from primary hæmorrhage, operative treatment is seldom called for before the patient reaches a base hospital. The conditions usually presented at a casualty clearing station are either a small deep traumatic aneurysm or, more commonly, an arterio-venous aneurysm of variable size, while in a few rare cases of severe reactionary or secondary hæmorrhage ligation may be indicated.

An aneurysm increasing in size or dangerously superficial in neighbourhood of wound may necessitate early operation, but all other cases are best treated by rest and observation. At the end of 14 days, if the tumour be stationary or decreasing in size, they may be transferred to the base, where spontaneous cure will sometimes occur after several weeks or operation can be performed when the limit of diminution is reached.

An aneurysm existing for even a few hours is the best preparation for ligature owing to the fact that the collateral circulation is gradually and not suddenly called upon to supply the area of deprivation, and can adequately cope with the requirements of the tissues when complete cessation of supply through the original channels is effected. This is well exemplified in the case of the popliteal artery where severance of the vessel by a bullet, even without much loss of blood, almost invariably leads to gangrene of the leg, while ligature for traumatic aneurysm very seldom does so; the Letouffier tube aims at the performance of this function of an aneurysm in the provision of a modified supply of blood while the critical period of collateral expansion is tided over.

During 30 months in a casualty clearing station, amongst a total of 44,000 wounded, I have seen only three cases in which ligature of the common carotid appeared to be indicated, each for one of the three conditions enumerated above—severe secondary hæmorrhage, dangerously superficial aneurysm, and a tumour which increased in size despite rest in bed.

CASE 1.—Private, wounded on Dec. 28th, 1914. Rifle bullet entered neck posteriorly at level of fourth cervical vertebra and one inch from middle line on left side. Ascending ramus of lower jaw and alveolus of upper on left side were shattered. Malar bone fractured but not comminuted, and whole cheek from mouth to ear torn in shreds. He was in a state of collapse and much exsanguinated when admitted to No. 2 Casualty Clearing Station eight hours after being wounded. An intravenous saline, containing two drachms of brandy, was administered, and this, combined with warmth, gave rise to severe reactionary hæmorrhage. The large gauze plugs in the wound were quickly withdrawn and, aided by the patient fainting, several large fragments of bone and loose groups of teeth were removed. No bleeding points were secure, but a ligature was applied to twisted end of facial artery which lay free in wound. Packing sufficed to arrest welling up of blood from deeper parts at the time, but on following morning another severe hæmorrhage occurred and under an anæsthetic I tied the external carotid through an incision extending from the wound.

For four days there was no further hæmorrhage, but the wound became extremely septic and the fœtor, associated with large wounds of the mouth, was unpleasantly pronounced. On fifth day violent hæmorrhage took place while patient was drinking some lemonade. The blood appeared to flow from the internal carotid where ulceration of vessel had probably occurred. He rapidly became semi-conscious and, under a light anæsthetic, I tied the common carotid through transverse incision. This wound was covered with gauze and collodium and remained aseptic throughout. This operation rendered him completely aphasic and hemiplegic for three days and very dangerously ill for a week. On fourth day he suddenly called out "Here," and this word was used to express all his wants until the seventh day when his vocabulary commenced to increase and, in certain moods, to intensify considerably. First voluntary movement of right arm and leg occurred also on fourth day after operation. He was very irrational for about 10 days and required nasal feeding on several occasions. When transferred to base, three weeks after last operation, the movements of limbs of right side equalled those of left in vigour and he was cheerful and sensible although still very weak. Five months later he wrote from Ireland to say that he was quite well except for "the extra little hole in his face."

CASE 2.—Private, wounded on July 26th, 1916. Shell splinter entered left side of neck at anterior border of sterno-mastoid immediately above level of cricoid. Prior to admission to No. 44 Casualty Clearing Station fine gauze plugging had been packed into wound and hæmorrhage successfully arrested. A large superficial arterio-venous aneurysm was present with loud "machinery" bruit and distinct "prickly" thrill. He complained of continuous roaring noises in the head, like breakers on a shore, which forbade sleep; considerable discomfort on swallowing or movement of head, but no actual pain.

As the aneurysm was large and dangerously near the surface, exposing him to risk of copious hæmorrhage on extrusion of plug, I ligatured common carotid on following day. No change visible in face on tightening of ligature. On removal of gauze plug from wound considerable venous hæmorrhage took place. The sac was freely exposed and the veins leading thereto, including internal jugular, were grouped together above and below and ligatured. As the hæmorrhage was thereby completely arrested, the artery which had been undisturbed at seat of injury was not ligatured distally. Missile not searched for. No post-operative symptoms. Noises in head had disappeared completely; no trace of paralysis or aphasia. He was transferred to base on tenth day after operation, and three months later wrote that missile had been extruded on Oct. 1st through small sinus at seat of original wound without operation, and he was about to have a board with view to return to active service.

The third case was undertaken for an enlarging tumour which proved to be an abscess in the laminæ of the original aneurysmal sac, and unfortunately ended fatally.

CASE 3.—Private, wounded on right side of neck by shell fragment on Oct. 24th, 1916. He was admitted as a walking case to No. 44 Casualty Clearing Station eight hours after being hit, with temperature 102° F. and pulse 120. Wound small and in mid-line of sterno-mastoid immediately below level of cricoid. No external hæmorrhage after admission, but patient said it had bled freely at first and then stopped of its own accord. A small deep pulsating tumour felt; distinct aneurysmal thrill and also a bruit, which was, however, more easily audible over temporal artery than through fascial and muscular layers.

The tumour increased in size for two days but caused very little discomfort, temperature and pulse falling steadily. On third day it was visibly smaller and continued to decrease in size until seventh day, when he felt "champion" and talked and ate with great gusto. On evening of eighth day pulse rose from 68 to 84 and temperature from 98·6° to 99·8°, the swelling being slightly larger. He slept well, however, and felt better the following morning. He complained of tiredness; towards evening respiration appeared slightly interfered with. The slight irritative cough which had affected him throughout sounded harsher. On following morning pulse had dropped from 96 to 82, temperature 99°, and he felt again a little better, but swelling had increased considerably towards root of neck, and lips and ears showed a slight degree of cyanosis. I decided to operate, and through long oblique incision first disarticulated and removed portion of inner end of right clavicle to have ready access to artery in event of rupture of sac. The common carotid was ligatured about 1½ inches above innominate bifurcation The tumour caused vessels of neck to curve outwards, while trachea and œsophagus were pressed over to left of middle line. The large tumour was then incised, and out flowed several ounces of creamy pus. When this had been mopped away an inner tumour about size of large hen's egg became visible—the actual aneurysm. The pus cavity, developed in intermediate laminæ of original aneurysmal sac, surrounded the aneurysm on all sides except posteriorly, and stretched up behind sterno-mastoid muscle to mastoid bone. Two fingers could be easily passed between œsophagus and prevertebral fascia. The aneurysmal sac was then incised and a finger placed upon bifurcation of carotid immediately below which lay an oval slit about 15 mm. in length on anterior aspect. Jugular vein appeared unwounded. A distal ligature was applied and the wound left open. The patient never rallied and died four hours later. Post mortem: Jugular vein found intact, but bound down with the vagus nerve in dense inflammatory tissue. Nothing beyond slight comparative congestion of left cortex observable in brain. Smear of pus showed numerous micrococci and several organisms closely resembling *B. perfringens*. Pericardium contained 152 c.c. of clear fluid. The small fragment of metal lay embedded in some enlarged deep cervical glands on left side.

The heart tires with great rapidity under even a small degree of respiratory embarrassment due to obstruction of the air-passages in the neck, whether the cause be aneurysmal or a wound of larynx or trachea. The facts of the external wound having practically healed over the sterno-mastoid, the masking of the presence of the pus stratum by the deep fascia, and the patient's appearance and sense of well-being until the morning of operation, appeared to justify the hope that a second diminution might occur. Delay in operation was disastrous, and the experience of this case would lead me in future to operate at once upon an aneurysm which, having become quiescent, again commences to enlarge.

THE MEDICAL REGISTER.—The official Register just issued contains the names of 43,481 persons, of whom 54·2 per cent. are on the local Register for England, 31·8 per cent. for Scotland, and 14 per cent. for Ireland. 1202 names (including 123 colonial and 7 foreign registrations) were added during the year, and 59 names were restored. 1005 names have been removed from the Register during the year: 983 on evidence of death, 14 under Sec. XIV. and 8 under Sec. XXVIII.-IX. of the Medical Act, 1858. This accounts for all the removals, it being significant that no registered medical man has formally removed his name as having ceased to practise.

DOWN DISTRICT ASYLUM, DOWNPATRICK.—During 1916 the total daily average number of residents in the lunatic asylum at Downpatrick was 778, 412 men and 366 women. The patients admitted were seven less than in the previous year and the net average cost per head showed an increase of only £2 16*s.* 9*d.* as compared with 1915, the amount received for the maintenance of paying patients being exceptionally large. From the farm there was a net profit for the year which ended March 31st, 1917, of £2142 4*s.* 9*d.*

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

DOUBLE DISLOCATION OF JAW SIMULATING FRACTURE OF THE SKULL.

BY E. C. HARE, M.R.C.S. ENG., L.R.C.P. LOND.,
LIEUTENANT-COLONEL, I.M.S.;
AND
SYDNEY J. COLE, M.D. OXON.,
MEDICAL SUPERINTENDENT, WILTS COUNTY ASYLUM, DEVIZES.

THE following case, in which double dislocation of the jaw backwards into the external auditory meatus induced symptoms simulating fracture of the base of the skull, gave rise to interesting diagnostic questions.

The case was that of a tall, well-built, well-nourished man, aged 23, who had been an inmate of the Wilts County Asylum since April, 1916, on account of epilepsy. The fits occurred frequently, were of a severe type, and attacked him without warning. He had a broken nose and several old scars on his face, the result of injuries sustained in falls that had occurred in previous fits. On March 15th last he was walking in one of the airing courts, when suddenly in a fit he fell forwards "like a log," and struck the point of his chin on the asphalt pavement. He was at once found to be bleeding not only from a deep lacerated wound on the chin, about an inch long, but also from both ears. Within a few minutes he was rolling about on the ground and moaning. He was carried into the hospital ward, and it was then found that his jaw had been driven backwards and was fixed almost immovably in the closed position. On attempting to move it, crepitus was felt, though no fracture of the jaw could be located. By the following morning he was able to talk and to drink milk; but he continued very stupid and apathetic, so that it cannot be stated whether his hearing was affected to any extent. There was some swelling and pain in the neighbourhood of each temporo-maxillary joint. Mobility of the jaw was not recovered, and the patient remained unable to take any but liquid food. The discharge from the ears was practically continuous, being bloody till the eighth day from the injury and then serous. On the eleventh day about a teaspoonful of pus came away from the left ear, and on and after the seventeenth day pus was exuding from both ears. On the seventh day the temperature rose rapidly and reached 102·8° F. Irregular pyrexia continued until the nineteenth day, after which, in spite of the purulent discharge from the ears, the temperature remained subnormal for several days, until after the onset of a status epilepticus. He had had occasional epileptic fits since the accident. On the twenty-sixth day the fits became frequent, 20 being recorded for that day, 10 for the twenty-seventh day, 27 for the twenty-eighth, and 15 for the twenty-ninth day up to the time of his death at 1.20 P.M. (April 12th). The fits appeared comparable to a typical status epilepticus and classical symptoms of meningitis were absent.

It was expected that a fracture would be found extending across the base of the skull, but post-mortem examination showed that there was no fracture of the base in the ordinary sense of the term. The base as viewed from within the cranium was intact, and there was no injury or recent disease of any of the cranial contents. There was a fracture of the tympanic plate of each temporal bone and septic arthritis of both temporo-maxillary joints. What had happened in the fall was that the condyles of the jaw had been driven backwards, smashing the tympanic plate, encroaching upon the external auditory meatus, and opening a way from the meatus into the joint, with the result that septic arthritis had been set up. There was no fracture of the jaw.

CASE OF ULNAR PARALYSIS; ULNAR-MEDIAN ANASTOMOSIS; RECOVERY.

BY J. K. HAWORTH, M.D., B.S. DURH.,
CAPTAIN, R.A.M.C. (S.R.); SURGICAL SPECIALIST, 8TH LUCKNOW DIVISION.

ON April 9th, 1916, in Mesopotamia, Private H—— was shot in the left forearm just below the elbow on the inner side by an explosive bullet. In December, 1916, he was admitted to Lucknow Station Hospital suffering from typical

ulnar paralysis of left hand. He complained that his hand was useless and he wanted something done. On examination the ring and little fingers of his left hand were flexed markedly and quite useless, and blue in colour. He could not move them and could feel nothing. There was marked wasting of the interosseus muscles. He could not move the fingers apart.

Operation, Feb. 10th, 1917.—A curved incision was made over the front of the left arm. The lower part of the ulnar nerve was found and seemed of fair size. The nerve was dissected out and taken under the flexor muscles and let into the median nerve by a valve-like slit, being held by a very fine catgut suture. The nerves were held in apposition by a skein of catgut passed round the nerves outside of a layer of membrane from the inside of a boiled egg. The wound was closed and healed perfectly. Sixteen days afterwards he noticed the two fingers were no longer blue, but pink and healthy-looking. He could just feel a little in them. Some days later he could move them a little. On examination, six weeks after the operation, the fingers looked normal. He could move them fairly well, even to extending them and flexing them to almost their full limit. He could feel quite well in them and could slightly separate them. He stated himself that the use of his hand was rapidly improving. He has been transferred to the Electrical Institute, Dehra Dun, for treatment.

Remarks.—The nerve may never have been divided by the wound yet held by very dense scar-tissue. Whether an attempt should have been made to free the nerve or not is doubtful. The scar-tissue would doubtless have bound it down again so it might appear that the cross anastomosis of nerves might be useful in similar cases.

Reviews and Notices of Books.

Surgical Therapeutics and Operative Technique. By E. DOYEN. English edition prepared by the author in collaboration with H. SPENCER-BROWNE, M.B. Cantab., Élève de l'Institut Pasteur; et Chef de Clinique de l'Institut Doyen. Vol. I. London: Baillière, Tindall, and Cox. 1917. Pp. 746. Price 25*s.* net.

THIS book is not a mere literal rendering of the French edition of Doyen's great five-volume work, but at Dr. Spencer-Browne's request the author rewrote several portions of the original before the translation was undertaken so as to make it exactly representative of the present practice of the clinic with which the two were associated as chief and first assistant. The English edition therefore represents the methods employed by a brilliant surgeon as improved by him nearly up to the time of his death. The volume now issued is a first instalment of three which are to contain the substance of the French five. Not the least interesting portion of this volume is the historical introduction, in which there are reviewed the methods which have from time to time been employed for the arrest of hæmorrhage. Chapters follow in which the instruments preferred are described, some of them at great length; for instance, nearly 10 pages and 17 illustrations are devoted to the account of the operating-table devised by Doyen. Many of the instruments were invented by him, a department of surgery in which he showed great ingenuity. While much of the advice given on surgical technique is sound, statements occur here and there which would not be endorsed by many surgeons. On two main principles the author specially insists. The first of these is that time should not be wasted in the course of an operation by ligaturing bleeding vessels. Doyen holds that many vessels are tied quite needlessly, for if the occlusion of these vessels had been left to the end of the operation many of them would not have required ligature at all. The second principle is bound up with the first; it is that operations should be completed as quickly as possible. When a tumour has to be removed it should be got away as rapidly as possible, for if this is done the shock to the patient is diminished and less blood is lost.

So far as the book may be judged by this first volume it will serve a useful purpose in laying novel ideas before the surgical reader, acquainting him with methods found useful by an adroit operator and furnishing valuable suggestions on the use of instruments. The translation is good on the whole, but phrases and expressions occur which are hardly current in medical English. We may quote a few examples. "A wen of the hairy scalp" is not an improved rendering for "a sebaceous cyst of the scalp." Readers may reasonably ask: Where is the "genal region"? What is a "recoil screw"? The sentence: "The phenol vapours chased the flies" has the virtue of being graphic if unusual, but "The pavilion of the ear" may merely mystify. Consultation of a good medical dictionary would clear up the difficulties, let it be admitted, but authors should not put this trouble on their readers unnecessarily. These are small matters, and only the translator knows the difficulties of his task, but at the present time when a large proportion of the medical profession can enjoy the Gallicisms in their original form, it should be the translator's task to render into current English.

The Involuntary Nervous System. By WALTER HOLBROOK GASKELL, M.A., M.D., F.R.S. With coloured figures. London: Longmans, Green, and Co. 1916. Pp. 178. Price 6*s.* net.

THIS first volume of the proposed series of monographs on Physiology, edited by Professor Ernest H. Starling, leaves physiological science painfully aware of the serious loss it has sustained by the regretted death of Professor Gaskell. It is to him above all others, as Professor Starling declares, that we owe our present knowledge of the involuntary nervous system. The monograph under review represents the finished product of the activities of one who for no less than 40 years devoted himself to the meaning of the nervous system and the problems that have arisen from its study. At a time when recent researches on the sympathetic nervous system have served to indicate its great importance physiologically and clinically it is gratifying to have from the hands of a master a consistent and harmonious account of the significance of the involuntary muscular systems in the higher vertebrates both from a morphological and from a physiological point of view.

It is difficult, in a brief review, to indicate even the general conclusions of a book which will repay perusal from cover to cover. Professor Gaskell divides the involuntary muscular systems of the body into various groups, vascular, ectodermal, endodermal, sphincter, and so on. The muscles of some of these contract under the influence of adrenalin, the endodermal only in the presence of acetyl-cholin. We have thus an adrenalin group and an acetyl-cholin group. These two groups are supplied by fibres from two distinct nervous systems—viz., the sympathetic nervous system (in the old sense) and the enteral nervous system. Further, the motor nerve cells of these two nervous systems are in turn connected with the central nervous system, again by two separate arrangements, the former by the thoracico-lumbar outflow from the spinal cord, and the latter by the bulbo-sacral outflow. The nerve cells of both these systems were, it is known, originally in the central nervous system and have travelled out from it. The cells of the sympathetic nervous system are linked to cells containing adrenalin (the chromaffin system), which presumably existed originally in the central nervous system as adrenalin-nerve cells, and became separated, though still associated, as they passed out. On the other hand, the cells of the endodermal system (enteral) have travelled out as far as the muscles themselves, and have been accompanied by inhibitory cells from the sympathetic system; in both cases there is abundant evidence of reciprocal innervation between the two groups, enteral and sympathetic. Of still greater speculative interest is Professor Gaskell's theory of the conversion of the nervous system of the invertebrates into that of the vertebrates. He believes that the central nervous system of the invertebrates has formed the central nervous system of the vertebrates by growing round and enclosing the alimentary canal of the former, so that the alimentary canal as found in the vertebrate is a new formation derived from structures already existing in the invertebrate ancestor. For the details of the process the reader must turn to the book itself.

As may be imagined, a monograph of this description, representing the considered conclusions of a lifetime of research, cannot be gauged by any easy standard of superficial criticism. Its appeal, however, is not to the physiologist alone. The scientific clinician will not fail to grasp

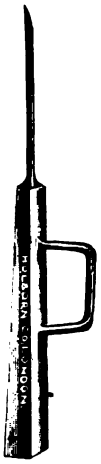
its bearing at many points on the phenomena of clinical medicine. It is a book of comparatively few pages, but it is deserving of serious study, and with its broad lines of investigation and wide outlook is eminently calculated to arouse interest and stimulate discussion.

Finch and Baines: A Seventeenth Century Friendship. By ARCHIBALD MALLOCH, M.D. McGill, Captain, C.A.M.C. Cambridge University Press. 1917. 4to. Pp. 89. 10*s.* 6*d.* net.

THE story of the friendship of the two seventeenth century doctors, Sir John Finch and Sir Thomas Baines, is one of considerable psychological interest, and Captain Malloch has told it exhaustively in this beautifully illustrated quarto volume. Every line of the text and the large number of references to authorities, living and dead, as well as quotations from written and printed manuscripts, prove that he has spared no pains to put the two seventeenth century worthies before us exactly as they lived. Almost always in the perpetual coupling of the names Finch comes before Baines, and in public life he occupied the more prominent position. Son of the Recorder of London, brother of the Lord Chancellor, professor of anatomy at Pisa, and English Ambassador at Constantinople, he led a full and distinguished life, but during nearly forty busy years in various European capitals he always remained in the closest touch with his college friend Baines. Together they left Christ's College, Cambridge, after graduation, together they toured Europe, and together they received medical degrees at Padua; Baines lived at Pisa during Finch's professoriate, and at Constantinople with his Embassy; both were knighted, though not simultaneously, and together they were made Fellows of the Royal College of Physicians of London; after 36 years of the closest business and intellectual intimacy they died within a year of each other; in their wills they both endowed their old College at Cambridge, and they were buried together in the College chapel. The probability is that each without the other was incomplete, and that Baines supplied for his more brilliant friend a certain weight and solidity of character wanting in the affectionate and credulous Finch, but such complete fusion of two identities, even though it be thus superficially explained, is none the less extraordinary. Captain Malloch has supplied us in this beautifully printed and illustrated book with an interesting historical and medical note.

JOURNALS.

Military Surgeon.—The April number of this journal opens with an article by Dr. Fielding H. Garrison on the foresightedness of Lauder Brunton in respect of the position of Great Britain on the occurrence of war. We comment on this article elsewhere. Surgeon R. G. Heiner, United States Navy, Instructor in Hygiene at the Naval Academy, writes an interesting paper insisting that it is quite easy to work for five or six days at high pressure with no food, or only carbohydrate food; that for the first 10 or 20 hours there is discomfort, but that afterwards there is loss of appetite and ability to work for 16 hours a day for the next five days, with marked increase in nervous and muscular energy. There should then be given a glass of milk, after which the man will sleep soundly for several hours, and waking will have a good meal and again go to sleep; on re-waking he will have a ravenous appetite and will eat heartily and sleep soundly for the necessary three days' rest period. His weight will return to the normal or a little above, and there will be little inconvenience when he again commences to fast and work. This system, Surgeon Heiner urges, will make the food-supply of armies much easier for generals, and will give artisans much better housing, saving, too, their daily train journeys, for they will sleep in airy dormitories at the works during their fasting spells and go home to their houses, far out in the country, for their week of rest twice only in a month. Exercise should be taken after eating, light exercise after breakfast, and the most heavy exercise after the evening meal. Stimulant, which seems to mean coffee, should be given after meals. This system would, he thinks, be of special advantage in the treatment of tuberculosis. The paper will well repay perusal, and everyone will remember how our soldiers, after a "big push," when they had done great work on small rations, did little when they returned but eat and sleep. The wounded, for three days after they returned to England, slept all the time, dropping off to sleep again at once after they had been wakened to take food. Captain E. C. Jones, Medical Corps, U.S. Army, has an article on military dogs, and mentions that three ambulance dogs after a battle in Manchuria found 23 wounded men when the Russian stretcher-bearers thought they had brought all in. He also tells how police dogs are used in New York City to assist policemen on patrol and notes that they prevent burglaries, finding concealed thieves so certainly that burglaries are not now attempted. Lutz, the French scout dog of Verdun, is mentioned, whose growling on Feb. 21st, 1916, gave the first warning of the German advance.



Maternity and Child Welfare. Vol. I., No. 5, May, 1917. 6*d.* net.—The plan adopted in this periodical of publishing several short articles on the same subject written from different points of view is a good one. This month the crêche is discussed in this way. The Atlas and Gazetteer of Child Welfare work is interesting; the Newcastle-on-Tyne district is dealt with. An article on the Federation of Hospital Treatment for Children, by Dr. C. J. Macalister, outlines a scheme for providing adequate treatment for sick children by the coöperation of the various hospitals and convalescent homes in any given district, with the Invalid Children's Association as a clearing-house. Such a scheme is already in force at the Royal Southern Hospital, Liverpool, and as the writer remarks, "If this can be done in connexion with one hospital, why should it not be carried out in connexion with them all?"

Correspondenz-Blatt für Schweizer Aerzte. 49. Jahrg. 1917, May 12. Basle: Benno, Schwabe, and Co.—Professor A. Jaquet recently retired from the controlling editorship, after being associated with the journal since its commencement 24 years ago, being succeeded by Dr. E. Hedinger, professor of pathology in Basle University, whose influence is seen in the present number, which contains nine closely printed pages of excellent abstracts from German, French, and English medical literature. Dr. Huber-Pestalozzi, of Zürich, writes on the treatment of gonorrhœa in Swiss troops at Solothurn, where he has carefully observed Ziegler's postulate not to interfere with the natural and beneficial hyperæmia and inflammatory reaction of the urethral mucous membrane so long as gonococci still remain.

New Inventions.

A NEW NEEDLE FOR THE INJECTION OF ARSENO-BENZOL PREPARATIONS.

A NEEDLE which I have devised for intravenous medication differs from previous needles used for a similar purpose in that it has a handle placed on the upper surface of its mount and over the centre of gravity of the instrument (see Figure), this giving a perfect sense of balance. The mount is of a special shape and is considerably longer than usual. In practice the needle is held by its handle (not by the mount as is the usual method), when it will be found that the "grip" so obtained imparts to the instrument a greater delicacy of touch than has hitherto been possible, and the surgeon can with the utmost ease give to the point of the needle every gradation of movement which may become necessary in order to ensure its entry into a vein; in this way the perception of control is absolute. The mount is 1½ inches long and takes the form of a square pyramid of such dimensions that when the instrument is lying on a horizontal surface the shank of the needle is directed downwards, thus ensuring that the point remains within the lumen of the vein after it has once been introduced. Further, by virtue of the length of the mount and from the fact that each of its four surfaces is flat the mount lies fairly and squarely on the skin while the injection is being made. In actual use the needle has been found to give extremely good results.

The needle has been made for me by the Holborn Surgical Instrument Co., of Thavies Inn, Holborn-circus.

THE LANCET.

LONDON: SATURDAY, JUNE 9, 1917.

Labour Conditions in Factories and Workshops.

THE annual Report of the Chief Inspector of Factories and Workshops for the year 1916 does more than chronicle the sanitary and industrial improvements which a third year of work under war conditions has produced. Perusal of it causes us to realise that out of the horror of war some good, at any rate, may result, and that our industrial workers in the future will profit by the revolutionary changes in their position brought about by the pressure of evil circumstances. The vast scale of the munition works has led to consequences in connexion with the pay and supervision of the workers which have necessarily affected other industries, and when the demand for munitions has ceased, and when those engaged upon producing them are released for other employment, the changed conditions will remain. The institution of "welfare supervision" has mainly followed upon the requisition of women as workers, and the change which their employment has produced may rank among the most important of the social results of the war. The Deputy Chief Inspector of Factories, Mr. H. M. ROBINSON (who signs the report in the absence of Sir ARTHUR WHITELEGGE through illness) shows how necessary the provision of suitable sanitary accommodation for women was found to be in the varied industries where they were able to replace men of fighting age and condition.

Miss A. M. ANDERSON, the Principal Lady Inspector of Factories, adds to the report a series of observations upon the Effect of the Third Year of War on Industrial Employment of Women and Girls, and those are of great interest and importance. In dealing with the general question of the substitution of women for men in industry Miss ANDERSON has definite information to give upon the performance by women of work which was generally believed to be outside the scope of their physical powers. There will always be some work which for physical reasons must be done by men—the fact that some strong women are the physical superiors of some weak men does not alter the case—and Miss ANDERSON finds the limit to the replacement of men by women to lie in certain heavy occupations where adaptation of plant and appliances cannot be effected so as to bring the processes to be carried out within the compass even of selected women. But excluding these occupations, Miss ANDERSON describes the result of judicious selection even in fairly heavy work to have been striking, adding that "it is permissible to wonder whether some of the surprise and admiration freely expressed in many quarters over new proofs of women's physical capacity and endurance is not in part attributable to lack of knowledge or appreciation of the very heavy and strenuous nature of much of normal pre-war work for women, domestic and industrial." That comparatively heavy work is unsuitable for women in itself, and is likely to injure them physically, is apparently not in any way demonstrated by the facts observed by factory inspectors. There appears to be no record of women giving up work on account of it being too heavy or having caused them physical injury, so that to estimate the extent to which such results have occurred or may occur is not possible; but we are told that it is rare to receive a complaint as to the heaviness of her job from a worker, and "the keenness, especially of very young girls, for work at present is pathetic," according to an inspector's report quoted by Miss ANDERSON. For this keenness, and for a zeal to undertake the class of work which has before been reserved for men, one main cause may be assigned. The allotting of rates of pay to women which have hitherto been for men only has had a peculiarly enheartening and stimulating effect, the difficulty being not to find women to undertake men's work at men's rates, but rather, when women have left what have been regarded as women's industries, to replace them in civil employ at the rates of pay prevailing hitherto for women. The result has been what might have been expected. In industries not connected with the manufacture of munitions employers are finding themselves compelled to offer higher wages, as well as to adopt measures for securing the comfort and health of those employed which go beyond the bare demands of the Factory Acts. That the results obtained will be permanent appears to us to be almost beyond question. The importation of women endowed with strength and intelligence in large numbers into the industrial market might have tended to reduce wages and render employers indifferent to the importance of hygienic conditions and all that welfare supervision implies, and may still do so if and when a glut of labour occurs after the war; but in the meantime good wages and, more recently, welfare supervision have contributed with patriotic zeal to bring women into the various industries in which they have now acquired training, and these conditions, once established, will be maintained.

From the whole document one thing emerges with particular clearness, and that is the importance of welfare work among the industrial population, and there seems to us no reason whatever why this work should not be found valuable among male workers as well as among female and juvenile. The case of the latter is more obvious, but it has long been recognised by good employers that much in this direction can be done for male operatives. The influence of overtime work, for example, is probably the same in both sexes, and it is a subject the scientific study of which has been much neglected in this country. But the war has brought it to the front, and it finds prominent notice in Mr. ROBINSON'S report. It is well recognised that continuous and excessive overtime produces a weariness and want of concentration among the

workers which detract from their efficiency—both the quality and the quantity of the output suffer. This point is established over and over again by examples supplied by the inspectors of factories and workshops, and these records, made at a time when the maintaining of the amount and quality of the work has been of vital importance, should do much towards providing for the workers of the future proper conditions of relaxation. It is not necessary to conjecture in what exact directions the currents of industry will flow when war is over to be perfectly certain that workers in the future will not submit to spend their lives in circumstances which they know can be brightened, or in an environment which they know can be rendered less harmful; and all medical opinion will welcome the establishment of this spirit. In the future there will be a demand, and one that cannot be refused, for healthy conditions of life on the part of the operative, and the creation of those conditions in our industrial centres will be insisted upon by an educated and enlightened public opinion. Thus, at any rate, the war will not have produced only misery and sorrow—the fruitless expenditure of wealth and of human life.

Mental Defect and Criminality.

THESE are days of strenuous medical effort and of natural pre-occupation with things military, but it would be matter for regret were the medical profession to overlook two papers, under the modest title of "Notes," contributed by Sir BRYAN DONKIN to recent issues of the *Journal of Mental Science*. Their purpose, briefly, is to comment on a few of the many questions that have arisen of late years out of the problem of the feeble-minded, and in particular on that aspect of the subject which is concerned with the connexion between mental defect and criminality. There are certain topics which have peculiar attraction for the clever, if non-expert, layman, who believes himself competent to deal with such on the basis of what he, a little complacently, calls the scientific method. It is remarkable how frequently the written productions of these men are dubbed "authoritative" by lay press reviewers, and hence become active in misleading serious inquirers. The authors often reveal a high order of cleverness, but it is usually coupled with a less high order of intelligence, and this is particularly true of the increasing literature on criminality, especially in its supposed relationship to mental defect. With no clear perception, or consistent use, of such terms as "crime," "criminality," "heredity," "degeneracy," which denote the very topic of discussion, the pseudo-scientist rushes in where the expert treads with hesitation, and effectually obscures the subject with a cloud of generalisations which will not stand critical analysis. Sir BRYAN DONKIN, than whom few, if any, can speak with more deserved authority, mercilessly pillories these "crude, ill-worded, and ill-considered statements, vitiated by undefined and nebulous terms, and further confused by 'cross divisions.'"

By dint of uncritical repetition of self-styled "scientific" investigations, absorbed in equally uncritical fashion by the reading public, who are unable to distinguish the rôle of the genuine research-worker from that of *vulgarisateur*, the Lombrosian theory that criminals are racial degenerates, and that criminality is hereditary, innate, or constitutional, has found wide acceptance, even in the ranks of the criminal. Sir BRYAN DONKIN, in an interview with a fairly intelligent convict, was informed by him with the assurance of a Hyde Park lecturer that a long course of misconduct was due to the "inheritance of his constitution from a drunken father," while another habitual offender said that as society manufactured criminals it ought not to blame him but to answer for him. If the criminal is born to crime, so must the law-abiding individual be born to abide by the law—an equally natural and equally effortless part to play; but the upholders of the doctrine of the born criminal do not appear to grasp this corollary. Another aspect of this particular doctrine of the born criminal may be alluded to. When it is carried to its logical conclusion we are landed in the metaphysical depths of determinism and irresponsibility; the human organism becomes a complex of reflex automatisms. But in practical life a general ability to choose one's lines of action is assumed; we *act* as though this is so, whatever be our attitude towards theoretical doctrines. In Sir BRYAN DONKIN'S words, the dispute about free will concerns the matter in hand no more than the actual conduct of some men depends on the opinions they hold on the nature and relation of mind and matter.

From long and patient scrutiny of the facts of criminality Sir BRYAN DONKIN states authoritatively that there are no special qualities, physical or mental, common to all criminals, and that criminality is no "unity"; he maintains, further, that the sole link between criminality and heredity is the occurrence of a larger proportion of congenital mental defectives among convicted criminals than in the population at large. All men are potential law-breakers; it is the traditional, not biological, heritage of moral or social experience that saves them. Perhaps the most interesting section of these illuminating contributions to a vexed subject is that in which the author draws clear distinction between inheritance and reproduction in its strict sense. We would urge social workers and other lay authorities to familiarise themselves with the significance of the following teaching, which is based on the work of ARCHDALL REID. So far from a man's "make-up" being referable *either* to natural—i.e., inborn—agencies *or* to acquired factors—i.e., use, experience, education, and so on—human characters are derived *both* from an inborn capacity for developing them *and* from some external stimulus appropriate for their development. There is inheritance without reproduction, but no reproduction without inheritance. It is, of course, a truism that the existence of any quality or character in an individual implies the inheritance of the capacity of development of these qualities or characters; this is true of everything that can be called a

"character" at all, and true of all human beings, social or antisocial. The problem, then, is to account for the actual outward expression of these innate capacities in the individual concerned. What of the innumerable influences that act on men from the cradle onwards? How often is it not said by one or other that he "owes" everything to the influence of some parent, friend, guardian? Men's characters are moulded by their environment in a fashion that no amount of statistical juggling can eliminate; the waifs and strays that enter some of our well-known charitable homes in abundance are weighted, to a high degree in many instances, by the inheritance of criminal capacities, but are these capacities reproduced? The whole fabric of training-ships, schools, homes, and reformatories would vanish at once were potentialities uninfluenced by external actualities. In short, human beings, from criminals to saints, as Sir BRYAN DONKIN says, are the products of their environment as well as of their heredity, but not of the one without the other. This is the view which should be kept steadily in the front in all our attempts to deal with the problem of the mentally defective.

Annotations.

"Ne quid nimis."

THE BIRTHDAY HONOURS.

THE Birthday Honours list issued on Monday last by the Prime Minister appeared contemporaneously with an extended list of honours and promotions directly connected with the conduct of the war. These latter honours, as far as they affect the medical profession, will be found on page 893. We give here a list of the members of the medical profession included among what may be termed the strictly birthday honours, though it is obvious that the recipients have in some cases rendered distinct military service. Dr. Frederick Taylor, President of the Royal College of Physicians and of the Royal Society of Medicine, receives a baronetcy, and knighthoods have been conferred on Professor T. K. Dalziel, Lieutenant-Colonel, R.A.M.C. (T.), lecturer on clinical surgery at Glasgow University; Mr. H. F. Waterhouse, Dean of the Medical School and lecturer on surgery at Charing Cross Hospital, lately surgeon-in-chief to the Anglo-Russian Hospital at Petrograd; and Colonel Robert Jones, C.B., A.M.S., Inspector of Military Orthopædic Hospitals, to whose labours are largely due the existence and efficiency of these institutions up and down the country. Lieutenant-Colonel C. A. Johnstone, D.S.O., I.M.S., has been appointed a C.B. in the Military Division. In the Colonial Office list, Mr. T. Hood, Director of Medical and Sanitary Service, Nigeria, and Dr. F. T. King, medical superintendent of the Seacliff Mental Hospital, New Zealand, have been appointed C.M.G.'s; and knighthoods have been conferred upon Surgeon-General E. Fiset, C.M.G., D.S.O., Deputy Minister of Militia and Defence, Canada, and on Mr. E. C. Stirling, C.M.G., professor of physiology in the University of Adelaide. In the Royal Victorian Order the C.V.O. has been conferred upon Captain R. R. Cruise, R.A.M.C. (T.), ophthalmic surgeon to King Edward VII. Hospital for Officers, and attached to the 3rd London General Hospital. The list includes the following Indian honours: Colonel Hormasjee Eduljee Banatvala, I.M.S., Inspector-General of Civil Hospitals, Assam, receives a C.S.I.; Lieutenant-Colonel D. W. Sutherland, I.M.S., Principal of the Medical College and School, Lahore, and Lieutenant-Colonel J. Anderson, I.M.S., retired, member of the Medical Board of the India Office, each receive the C.I.E.; while Captain R. H. Bott, I.M.S., professor of surgery at the Medical College, Lahore, and Dr. Behari Lal Dhingra, chief medical officer, Jind State, have been awarded the Kaisar-i-Hind Medal of the first class. In the name of the medical profession we congratulate all these recipients of deserved honours.

BLOOD PRESSURE AND LIFE ASSURANCE.

THE observation of the arterial blood pressure in examinations for life assurance has of late years become common, especially in America; it is required by the medical forms of some companies, especially when the proposer is over 40 years of age. The value of the record is, nevertheless, uncertain; it is usually only the systolic pressure which is given and on a single occasion; the reading varies under manifold temporary influences, and it is difficult to distinguish between these and more permanent organic causes of altered pressure. Efforts have been made to place the practice on a firmer scientific basis. In 1911 statistics were published by Dr. J. W. Fisher of the mortality of persons with increased blood pressure accepted or declined by the North Western Mutual Life Insurance Company in the United States. These showed a greatly increasing death-rate when the systolic pressure was over 150 mm., but the period of observation was only four years. Dr. F. de Havilland Hall laid some similar records before the Medical Society of London in 1912.[1] Two recent meetings of the Assurance Medical Society in London, on March 7th and May 2nd, were occupied with an attempt to elucidate the pathology of increased pressure. Dr. H. Batty Shaw brought forward an elaborate study of 50 cases of persons dying in hospital from various diseases, in whom "hypertension"—i.e., systolic readings of 150 mm. or over—existed. Besides summaries of sex, ages, occupations, and symptoms, detailed reports of post-mortem examinations were given, especially of the kidney condition microscopically. Numerous charts of the pressure readings showed great variation from day to day, even in uniform hospital conditions, and in some an intermittency hard to explain. The author was led by his studies to regard hypertension as a disease of "pre-renal" site and origin, so far in seeming accord with the theory of Gull and Sutton, who placed the vascular disorder prior in time to that of the kidney. Sir Richard Douglas Powell regarded the two conditions as independent, though often associated, and Sir T. Clifford Allbutt pointed to cases in which there is simple increased blood pressure, while he would class the majority of high-tension cases as renal. Many points of interest were raised by other speakers, and the importance of the subject can hardly be exaggerated. In one group of instances alluded to by Dr. Hingston Fox increased pressure was held to be due to temporary causes, and such a condition is often toxic from alimentary or hepatic disorder. In life assurance work such cases should

[1] THE LANCET, 1912, i., 1406.

be postponed for a second examination after suitable treatment; mercurials, salines, and a restricted diet generally reduce the tension. A considerable range of blood pressure is consistent with good health. With some the systolic pressure is naturally high, and such persons may lose their sense of well-being if it falls below 140. There is, again, the subject with habitually low pressure, who is fain to get up and walk about his room to help him to think. In view of the natural rise with age, especially at the climacteric, a periodical testing after the age of 40 years would be a good practice. No decisive indication as to the effect of tobacco on blood pressure has been reached. In an extreme instance quoted by Dr. H. W. Collier, a man of 34 had smoked very largely since childhood: his systolic reading was only 98. The relative importance of systolic and diastolic pressures was raised by some speakers at the discussion before the Assurance Medical Society; records were submitted, and it was urged that the diastolic readings, indicating the minimal constant pressure in the artery, gave a truer indication of the strain upon the vessel, and were much less under the influence of posture, exercise, and emotion. Others objected that reliable diastolic readings were difficult to obtain. We may point out, however, that, thanks to the late George Oliver and to Professor MacWilliam, of Aberdeen, the auscultatory method has now been developed in a form easy to practise. Further observations are needed, and the influence of peripheral resistance, and the modern view of the stimulation of a weak ventricle by automatically induced increase of pressure must, among other factors, be taken into account. But it seems likely that diastolic pressure records will in the future attain increased importance for purposes of prognosis.

THE FOOD ALLOWANCE FOR BOYS AND GIRLS.

THE medical officer of health of Bristol City, Dr. D. S. Davies, has recorded a recent experience of revising the dietary of an institution for growing boys which has warned him that considerable life-long injury might be caused to boys and girls by insisting upon a too strict régime in their cases. Of course, the needs of the growing and developing individual are more important than those of the adult, and this point has already received official attention, for in one of the pamphlets published by the Ministry of Food it is rightly stated that children need plentiful food for three reasons: first, their surface is large compared with their weight; secondly, they are growing; and thirdly, they are almost always very active compared with many adults. It is generally conceded that a child of 8 needs half as much as a grown-up and a child of 12 three-fifths as much, while a girl of 16 needs as much as her mother and a boy of 16 may eat as much as his father. In these cases the foundations of fresh tissue for development are being laid down, and this goes on until the phase is reached of complete manhood and womanhood. Upon the conditions of nutrition of growing boys and girls depends the future physique and mentality of the race. Parents and guardians will do well to bear this in mind when the question of rationing juveniles is being considered. Food should not be dealt out to these in proportion to age, the children getting but a fraction of the dose for an adult. The parent must spare for the child.

THE MEDICINAL USE OF GLYCERINE.

THERE is now no glycerine being allotted for medicinal purposes, and pharmacists who have exhausted their supply can only obtain more by borrowing from those who have some left. As we noted four months ago the Ministry of Munitions considered that the stocks then in the hands of pharmacists should be sufficient to meet the legitimate demands of prescribers. An analysis of prescriptions undertaken by the *Chemist and Druggist* 30 years ago showed that glycerine came out ninth on the list of favourite drugs, and its use both in mixtures and as a toilet preparation has probably much increased since then. But neither as a solvent, a demulcent, or a flavouring agent is glycerine at all indispensable, and medical men would do well to assist the pharmacist in restricting its use to the few remaining purposes—perhaps in the case of calf lymph or in organo-therapeutic extracts—in which hardship would result from its withdrawal. It should hardly be necessary to point out that to prescribe glycerine freely in a lotion might place the conscientious pharmacist in a difficult position. He is prohibited by law from supplying it direct to one customer for toilet purposes, and it would be invidious for him to supply it to another customer for the same purpose on a medical man's order.

ANÆSTHETICS IN MILITARY PRACTICE.

THE adminstration of anæsthetics at or near the front was described recently in an admirable paper by Captain Geoffrey Marshall before the Section of Anæsthetics of the Royal Society of Medicine.[1] The author, in spite of the stress and hurry of a busy casualty clearing station, made scientific clinical observations on a number of cases, and his conclusions form a valuable addition to our knowledge of the factors that should indicate the choice of anæsthetics and the methods of administration in the exceptional conditions of shock, hæmorrhage, and septic toxæmia. Perhaps the most striking lesson which Captain Marshall draws from his observations is the danger of chloroform and of spinal analgesia in the presence of the combination of shock and recently produced anæmia. In civil practice we are familiar with the baneful effect which anæmia has in influencing the behaviour of the anæsthetised subject; when that anæmia is grave and recently produced the effect is so pronounced that the proper selection and administration of the anæsthetic may make the difference between life and death. The use of "gas and oxygen" or of warmed ether vapour should result in saving lives in these critical cases.

PREPAREDNESS.

THE April number of the *Military Surgeon* opens with a paper entitled "An Apostle of Preparedness," discussing the teaching of Lauder Brunton, and written, of course, before the United States had come into the war. The writer, Dr. Fielding H. Garrison, lieutenant in the Officers' Reserve Corps of the U.S. Army, addresses himself particularly to the volume of essays on physical and military training written by his old teacher in the last 17 years of his life. Brunton secured less popular support for his views than they deserved because he tried too openly to introduce

[1] THE LANCET, 1917, i., 615.

a disciplinary spirit into the games of children when the value of such a spirit was not apparent to a public living in a fool's paradise. His essays breathed a spirit of patriotic anxiety, and we can see now that their comprehension might have provided us with better recruits for the war, besides making the training of those recruits more even and freer from the occasional disasters which are noted clinically as "disordered action of the heart." Exercises, Brunton thought, should be generalised, those that educate only particular groups of muscles requiring to be corrected by games; and exercises should be only gradually increased lest over-exertion cause wasting of the muscles involved, impairment of the respiration, and strain and consequent weakness of the heart. He noted that the Russian recruit, when he left the army and returned to his village, could nearly always get 25 to 50 per cent. higher wages than the other young man who had not had his military training, and that in Switzerland, where only 75 per cent. of the young men were found fit for service, and only the best of these were selected for training, not to be accepted as a volunteer was regarded as a disgrace. This readiness and training for service may have saved Switzerland from disaster in the war.

THE DIAGNOSTIC CHARACTER OF EFFUSION IN MELANOTIC SARCOMA.

IN the *American Journal of the Medical Sciences* for May Dr. C. C. W. Judd has called attention to the diagnostic character of the effusion in melanotic sarcoma—an important point, as the diagnosis is often missed before an operation is performed. In two cases the usual characteristic signs—melanuria, pigmentation of the skin, or suspicious tumour of the skin or choroid—were absent, but fluid obtained by paracentesis showed almost identical appearances. When agitated it was quite opaque, even in thin layers. On standing, a dense, dark, brick-dust sediment formed, while the supernatant fluid, though intensely pigmented, was clear and of a dark reddish-brown colour. The surface layer was slightly iridescent, with a predominant greenish tone. The foam obtained by shaking had a tendency to a pinkish hue in the first case and to a dirty olive-green in the second. The supernatant fluid when tested with perchloride of iron gave no reaction for melanogen, but on addition of bromine water a yellow cheesy precipitate formed, which became much darker on standing, and finally black, indicating that the formation of melanin from melanogen had been completed during life. Tests for bile pigment were negative. Microscopically the sediment showed red corpuscles, epithelial cells, numerous leucocytes, and many tumour cells containing the typical pigmented granules of melanoma. In the first case the patient was a spinster, aged 40 years, who began to spit blood on May 1st, 1914, and to lose weight and strength. Examination on May 15th showed at both apices loss of resonance, prolongation of expiration, and numerous fine râles after coughing. Early tuberculosis was diagnosed. She was admitted to a sanatorium and her temperature seemed to confirm the diagnosis. She improved, but continued to expectorate sputum streaked with blood for eight months. The adventitious sounds largely disappeared. The sputum was repeatedly examined, but never showed tubercle bacilli or any cells suggestive of malignant disease. On Jan. 6th, 1915, she felt slight pain on the left side, and a few days later she felt a gurgle within the chest. Ten days later there was dullness at the left base with skodaic resonance above. Hydropneumothorax was diagnosed and puncture showed the effusion to be "bloody." On Feb. 13th paracentesis was performed to relieve pressure symptoms. The pleura at the sixth interspace in the axillary line was markedly resistant to the introduction of the needle. Twenty-four ounces of coffee-coloured fluid were removed. Reaccumulation necessitated repetition of the operation about every five days. The fluid obtained on Feb. 24th was the first to reach Dr. Judd, and had the characters given above. At the site of the first puncture a pigmented growth developed. Death occurred on April 6th. The necropsy showed melanoma of the lung. In the second case the patient was a very dark man, aged 34 years, who suffered from great abdominal enlargement. There was almost general dullness, which did not alter with posture, but fluctuation was elicited. Paracentesis yielded three litres of coffee-coloured fluid, with the characteristics given above. In the right upper quadrant a firm indefinite mass was then felt. Two days later the skin, which had been dark and slightly sallow, showed numerous small dark moles. As the patient was relieved he insisted on leaving hospital.

CHINA AND WESTERN MEDICINE.

IN calling attention a year ago[1] to the holding of the first annual conference of the National Medical Association of China, we predicted that progress was likely to be rapid. This opinion is confirmed by the report by our correspondent on p. 889 of the second conference held jointly with the China Medical Missionary Association, at which it was resolved to establish a central medical council for China with functions similar to those executed by our own General Medical Council—e.g., to fix a standard of medical education, to draw up a code of regulations, and adopt a uniform system of medical nomenclature. At the two sessions of the conference the presidents of the two associations—Dr. W. H. Venable, of Kashing, and Dr. Wu Lien-teh (known in this country as G. L. Tuck)—occupied the chair alternately. Much remains yet to be done in overcoming the prevailing conservatism of the Chinese in medical matters, which is in striking contrast with the receptivity of their Japanese neighbours. In the June number of the journal of medical missions, issued by the Church Missionary Society, Miss P. S. Tsêng, B.Sc., the first Chinese woman graduate of London University, speaks of the deeply-rooted prejudice of the Chinese against operations, a prejudice only overcome to any great extent in the coast provinces where the work of the missionary hospitals is seen and appreciated. She quotes an alarming figure for the incidence of tuberculosis in such a crowded centre as Hangchow, giving it by hearsay as 70 per cent. of the population. In view of this it is satisfactory to note the progress made in the opening of new hospitals and centres of medical work. The Central Hospital at Peking is to be opened in the coming September, the China Medical Board of the Rockefeller Foundation having entirely taken over responsibility for the Union Medical College with its annual budget of $53,000, and placing Dr. Franklin C. McLean, a

[1] THE LANCET, 1916, ii., 332, 336.

graduate of Chicago and Rush, at its head. The Board is also establishing a medical college in Shanghai, as well as offering liberal support to all missionary hospitals within easy reach of those centres in which medical schools exist. This enlightened policy of the China Medical Board, which also grants fellowships in the United States for graduates of Chinese medical colleges, cannot fail to have a beneficent influence on the development of Western medicine in China.

THE MINISTRY OF PUBLIC HEALTH.

WE understand that the Cabinet has favourably considered the scheme laid before it for the establishment of a Ministry of Public Health, and that the views of the Friendly Societies are to be taken on the subject. Whatever form the administrative centralisation of public health matters may assume, there is no reason to believe that the turning of the medical man into a State official will play an essential part in the scheme; but the general practitioner, whether in panel practice or no, will welcome any opportunity offered of making his point of view felt.

THE DISEASES OF ANIMALS DURING THE YEAR 1916.[1]

THE annual incidence of the diseases of animals is always of more than passing interest to the medical profession, as there are a number of diseases transmissible from animals to man. Rabies, anthrax, glanders, and mange may be cited as the principal ones, and statistics of their prevalence are given in the latest report of the Board of Agriculture and Fisheries. Rabies attracted attention this year by the occurrence at Oldham of a suspected case in a dog. Due precautions were taken, but it was eventually decided that the case was not one of rabies. The control of anthrax and glanders is now of especial importance on account of the large numbers of animals grouped together under war conditions, and the fact that no great outbreaks have occurred speaks volumes for the methods adopted by the Veterinary Department. Glanders especially, a disease which used to be the scourge of armies in war-time, is practically non-existent. If a case does occasionally occur, the weeding out by means of the mallein test is such a simple matter that the veterinarian has not now the slightest dread of this disease. Foot-and-mouth disease has given a little more anxiety, but the outbreaks were quickly got under control and the country is again free. The report concludes with tables of statistics.

Dr. A. E. Shipley, F.R.S., Master of Christ's College, Cambridge, has been elected Vice-Chancellor of the University for the year beginning Oct. 1st.

A MEETING of the Section of Medicine of the Royal Society of Medicine will be held on Tuesday next, June 12th, at 5.30 P.M., when Major Aldo Castellani will give a lecture, with lantern demonstration, on Tropical Diseases to which the Allied Troops are Exposed in the Balkanic Zone. We call the attention of our readers to a meeting which is sure to be of exceptional interest because the notice has been unavoidably very short.

THE ANTISEPTIC "FLAVINE" (ACRIFLAVINE).

THE following has been officially communicated to the press by the Medical Research Committee:—

The incomplete statements which have appeared from time to time in the press with regard to the antiseptic "Flavine" have necessarily led to some misapprehension of the situation by the public. The impression has been created that flavine is a substance of magical potency which can cure infected wounds, and that there has been an unnecessary delay in making supplies of it available for general use. It should be realised that no antiseptic, even a theoretically ideal antiseptic when that is obtained, can ever be more than an adjunct to skilled and thorough surgery. Flavine must be thought of accordingly in relation to the other new antiseptics which have been brought into successful use during the course of the war.

These fall into two main classes. One depends upon the use of chlorine compounds, as in the well-known "Eusol" introduced by Edinburgh workers, the similar "Dakin" solution and the more recent chloramine-T, introduced by Dr. Dakin from the Leeds laboratories. These have wide use in our armies, and are now known all over the world. The researches from which these arose, and which are still in progress, have all been supported from the beginning by Government help through the Medical Research Committee. The second class, to which flavine belongs, includes the elaborate compounds of which most are brilliantly coloured and are used as dyes. From the first month of war special searches have been made among those on behalf of the Research Committee for unrecognised antiseptics of high value. Work at Haslar and at the London Hospital for the Committee showed very early the value of malachite green, and this is giving valuable routine results in naval hospitals and elsewhere. When it was desired to investigate flavine, which was a little-known but patented German dye, none was available in this country, and its manufacture requires highly skilled and laborious work. The Committee, however, caused a supply to be specially made in their Biochemical Department for investigation by Dr. Browning at the Bland-Sutton Institute. His remarks were first published in January, 1917. Three months previously, however, as a result of the first preliminary experiments, the Committee arranged that preparation should be made for the difficult processes of commercial manufacture, and all the scientific information at their command was made freely available. As a result of this early action they were able to supplement their own supply in use for the first laboratory experiments and clinical trials by a large number of samples, which were sent in April to a selected group of consultant surgeons to the Forces and other responsible surgeons for the purpose of securing official reports for the guidance of the Admiralty, the War Office, and civilian institutions, whose action could not rest upon any single testimony or any small-scale supply of the antiseptic. It is already clear that the special uses of flavine for particular purposes have still to be carefully defined in relation to other antiseptics and to the operative methods of surgery, to which it can at best only be a valuable aid. While this concerted official study is in progress two or three firms are already preparing for commercial supply to the public. Under our patent law it has been necessary for them to procure licence to manufacture from the Board of Trade. The hearing of applications for licences has already taken place, and it is hoped that licences to manufacture will very shortly be issued by the Board. It is proposed that all the manufacturing firms shall use one and the same name for the substance, a condition which will restrain any firm from securing monopoly privileges by wide advertisement of a fancy name. The Medical Research Committee have proposed for important technical reasons that the substance shall be officially called "Acriflavine" in this country. This will avoid the German name "Trypaflavin," which is registered as a trade-mark, and prevent confusion with an existing vegetable dye already called "Flavine." No doubt the firms concerned will announce at the earliest moment their readiness to supply acriflavine commercially.

During the progress of this work the Committee have more recently put at Dr. Browning's disposal for study a

compound closely allied to acriflavine which already appears to have identical or even superior properties, and if this be confirmed it will be easier to manufacture and cheaper for the public. This substance will be officially known as "Proflavine." An early scientific publication will be made on this subject.

The degree of Government support which has been given from the beginning to the researches upon acriflavine and other antiseptics has not always been made a matter of public knowledge. It is proper that financial and scientific help given officially should not diminish in any way the credit due to individual scientific workers or scientific institutions.

MEDICAL AFFAIRS IN CHINA.

(FROM OUR OWN CORRESPONDENT.)

The Peking Central (Model) Hospital.

AN important landmark in the progress of medical science in China is the approaching opening of the Peking Central Hospital next September. This hospital, when completed, will be the most up-to-date in the land, whether foreign or Chinese. The Government has supplied half the funds, and the other half has been obtained by public subscription. It will be managed by a Board of Trustees, whose qualification to office will be a subscription of at least a thousand dollars. The moving spirit of this deserving institution is Dr. Wu Lien-teh, who has travelled all over China and even as far as the Straits Settlements to enlist the support of wealthy Chinese. It is intended as a model in equipment and management, so that the thousands of officials who visit Peking may carry back with them some idea of the enormous advances which medicine has made in other parts of the world.

The hospital is a thoroughly modern structure, with central hot-water heating and the latest plumbing. The building is grey, with a red tile roof, and is beautifully situated, for from the roof garden of the west wing there is a lovely view over the hills, while from that of the east wing the renovated Mongolian pagoda of the Winter Palace and the temples of the Coal Hill are clearly visible. The whole building is of reinforced concrete, and is the only really fireproof structure in Peking. All the accommodation of a modern hospital is provided—that is to say, that in addition to the general and special wards, examination- and waiting-rooms, bathrooms and lavatories, and service block, there is a special-diet kitchen, analytical and bacteriological laboratories, private wards, and roof-garden shelters for heliotherapy and the restoration of convalescent cases.

Hong-Kong University.

At the first Convocation of the Hong-Kong University degrees were conferred for medicine, engineering, and arts. The most interesting part of the ceremony was the conferring of honorary degrees by the Governor of Hong-Kong, officiating as Chancellor. Of the five recipients of honorary degrees, two were Frenchmen and three Chinese. Both Frenchmen had contributed much to the knowledge of archæology in the Far East. The three Chinese were Sir Robert Hotung, a leading merchant in Hong-Kong, who among his considerable benefactions to the University founded the chair of clinical surgery; Mr. Jeme Tien Yow, a famous Chinese railway engineer; and Dr. Wu Lien-teh (G. L. Tuck).

The Resolutions of the Recent Joint Medical Conference.

I referred in my last letter to the two resolutions concerning the control of morphine and the institution of a Central Medical Council for China, passed by the Joint Medical Conference recently at Canton. I now send the text of these clear pronouncements.

The following is the resolution regarding the control of morphine:—

Whereas the National Medical Association and the China Medical Missionary Association, in joint conference assembled, have heard with deep concern of the enormous and rapidly increasing importation into China of morphine, and whereas such importation is largely surreptitious, therefore be it resolved that the National Medical Association and the China Medical Missionary Association place on record their conviction that the uncontrolled use of this drug will do far more harm to the nation than was ever done by opium, and believes that this imminent danger can only be averted by the Chinese Government enforcing without delay the provisions of the Hague Opium Convention of January 23, 1912 (including adequate pharmacy laws) so as to confine the employment of morphine to legitimate medicinal uses.

The following is the resolution regarding the formation of a Central Medical Council:—

Whereas during the Joint Conference of the National Medical Association and the China Medical Missionary Association great emphasis has been laid by the President of the National Medical Association on the need for a central organisation which shall regulate the curriculum and standards of medical schools throughout China, and shall control admission to the practice of Western medicine in this country; and whereas the experience of other countries has clearly shown that only by such centralised organisation can orderly progress be attained; and whereas the National Medical Association has expressed its belief that joint action in the matter is desirable at this time; therefore be it resolved, that this joint conference of the National Medical Association and the China Medical Missionary Association records its belief that only by the creation of a Central Medical Council can the needed regulation and control be effectively secured. Such council should include among its duties: 1. The fixation of a minimum standard of general education required of students before entering upon medical studies. 2. The maintenance of a student register on which the names of all who, having complied with the entrance requirements, have commenced the study of medicine shall be recorded. 3. The fixation of a minimum medical curriculum. 4. The supervision of examinations. 5. The recognition of hospitals where medical students and graduates may obtain clinical teaching. 6. The drawing up of laws and regulations affecting the medical profession in China, and their enforcement. 7. The issuing of a medical register containing the names of all those qualified to practise Western medicine in China. 8. The adoption of a general nomenclature of medical terms in Chinese. And further, that in view of the rapid increase in the number of students and practitioners of Western medicine in China, this conference requests the National Medical Association to approach the Board of Education with a view to the formation of such a council at an early date.

NATIONAL HEALTH INSURANCE.

The Public and Panel Practice in Birmingham.

IN our issue of May 19th we dealt with the comments of the London Panel Committee on the recent circulars D 8 and D 9 addressed by the British Medical Association to various bodies interested in the administration of National Insurance. In Birmingham a committee jointly appointed by the Panel Committee and the Executive Committee of the Central Division of the British Medical Association have arrived at conclusions not far differing from those formulated by the London Panel Committee. General satisfaction on the part of the insured is recorded, based upon evidence as to diminishing numbers of insured persons seeking medical advice as private patients, as to few changes of doctor at the end of each year, and few complaints coming before the Medical Service Subcommittee. The causes of dissatisfaction, where it exists, are stated to be principally lack of sufficient and appropriate examination, and insufficient attention, which cannot be wholly ascribed to war conditions—grounds of complaint which are admittedly serious when they are proved to occur. Certification difficulties and lack of uniformity in the procedure of different societies are also matters suggested for future reform. The medical man who is entirely devoted to panel work is said to give the most satisfaction to his panel patients. The number of general practitioners who have not joined the panel in the district under comment is about 80, as compared with about 260 who have done so. The report does not express any expectation that those now declining panel service would be induced to come in, even under the improved conditions which it considers practicable. A sufficiency of private practice, a dislike to being tied by contract, and lack of definition in the terms of contract and service are among the reasons assigned for this. It is noted that among those on the panel an improved panel service is generally considered likely to prove preferable to a salaried State service.

One of the questions propounded by the Insurance Commissioners is as follows:—

What extensions of the present provision in respect of medical benefit do you consider are required to make the service an adequate one?

The reply given is that the service will only be adequate when it provides for—

(*a*) A consulting or special opinion in necessary cases by a panel of consultants, who would see the insured persons in their own houses or at the consultant's rooms as occasion required. (*b*) Institutional in-patient treatment to be carried out by private practitioners in consultation with physician or surgeon, with operations by surgeons. (*c*) Complete service of necessary laboratory work for diagnosis, vaccines and serums, and X ray. (*d*) Nursing in their own homes by an amplified system of district nurses, which would allow

the continuous attendance of a nurse for short periods in suitable cases. (*e*) Dentistry, to include the provision of dentures. (*f*) Convalescent homes. (*g*) Instruction by lectures.

Among other suggestions made may be mentioned one that 2500 should be the largest number of patients permitted for any member of the panel, it being recognised at the same time that much depends upon the circumstances of a practice and upon the individual capacity of the practitioner. It is asked with regard to certification that uniformity in requirements as to the issue of certificates should be made compulsory upon all societies, and that in cases of chronic incapacity certificates at intervals of four weeks should be deemed sufficient.

The recording and comparing of opinions such as the above cannot fail to prove useful when the opportunity comes to amend the conditions of National Insurance, thus benefiting the insured person and the profession responsible for his health.

Obituary.

EMIL VON BEHRING,

EXCELLENZ; DIRECTOR OF THE INSTITUTE OF HYGIENE IN MARBURG.

Emil Behring was born at Hansdorf, in West Prussia, on March 15th, 1854, the day following the birth of his great compatriot, Paul Ehrlich. After qualifying in medicine at Berlin, he entered the Army Medical Corps, becoming in 1888 lecturer at the Army Medical College in Berlin, and it was not until he was 35 years of age that he became assistant at Koch's Institute for Infectious Diseases, undertaking as his first research the disinfecting properties of iodoform, which led his thoughts into the channels of problems of immunity. The bactericidal property of cell-free blood serum then claimed his attention, and especially the behaviour of serum in animals which had been exposed to the bacterial toxins which Roux had just described in Paris. Working alone on diphtheria toxin and in association with Kitasato on tetanus toxin, "the possibility of successfully treating cases of acute infectious disease" became the theme of a research published in the *Deut. med. Wochens.* in December, 1890, entitled "Über das Zustandekommen der Diphtherie-Immunität und der Tetanus-Immunität bei Tieren." Clinical experience, accumulated largely by Heubner, confirmed these experimental results, and at an address on the Aims and Achievements of Serum-therapy at the Naturalists' Congress in Lübeck (1895) Behring was justified in saying: "I have no fear that the thought which forms the basis of serum-therapy will ever disappear out of medicine." He estimated the probable saving of 75 per cent. of the mortality from diphtheria in Germany, an annual credit of 45,000 human lives. For this work Behring shared with Roux the 25,000-fr. prize of the Paris Academy of Medicine and the 50,000-fr. prize of the Institute of France. In 1901 he received the Nobel prize for Medicine, and delivered an address in Stockholm on Serum-therapy, while his progress in the receipt of official recognition at home reached the highest level of Excellency in 1903.

In 1895, when he was 41 years of age, Behring was appointed director of the Institute of Hygiene at Marburg, and from this time on he achieved nothing further corresponding to the five years of successful scientific work at Berlin. Ill-health already obliged him to give up the teaching function attached to the directorship and he only gave an occasional public lecture. He became financially interested in the manufacture of antitoxic serum by the Farbwerke Höchst which built and equipped admirable laboratories for him, in which he conducted researches involving, it is stated, 7,000,000 ounces of tubercle cultures. The bovo-vaccine which he devised for the immunisation of calves against tuberculosis formed the mainstay of another great commercial undertaking named the Behringwerk, and Behring was able to become a large landed proprietor with a population of cattle on which to test immunisatory processes under his own eye. Bovo-vaccine was also largely employed in Russia, Sweden, and America, with results which excited keen interest at the time, but which do not appear to have survived the test of time and prolonged experience. Behring himself, who started with the firm belief that human and bovine tubercle are one, had a period in which this conviction waned, and returned again to the unitarian view. "Phthisis," runs a much-quoted sentence, "is but the end of a lullaby sung at the cradle of the prospective consumptive." And whatever may have been the practical outcome of his experimental work there is no doubt that Behring has profoundly influenced contemporary thought in the direction of looking on tuberculosis as a lifelong affection. After suffering severely from periods of depression, von Behring's life was terminated by a sharp attack of pneumonia on March 31st, 1917.

JOHN MITFORD ATKINSON, M.B.LOND., M.R.C.S.ENG., L.S.A., D.P.H.CAMB.

John Mitford Atkinson died on May 23rd at his residence in West Kensington at the age of 60. The only son of the Rev. Samuel Atkinson, he received his early education at Queen's College, Taunton, proceeding thence to the London Hospital. As a student he had a successful career. He qualified M.R.C.S. Eng. and L.S.A. in 1878, taking the M.B. Lond. in 1881, and when home on leave from China, the D.P.H. Camb. in 1894. For a time he was assistant resident medical officer to the Kensington Infirmary, where he had for his senior colleague the late Henry Percy Potter. Here he learnt the details of management of a large medical institution, which later he turned to good account. In 1887 he was appointed superintendent of the Government Civil Hospital, Hong-Kong. At that time the hospital had no European staff of nurses, and its reputation was not at all high. He set to work to bring the administration of this hospital up to the professional level of the large general hospitals in London. At the beginning he had to face many difficulties, partly official and partly inherent in the local conditions and the prejudices of the Far East. All these difficulties he surmounted, and he succeeded in gaining the confidence, support, and esteem not only of his official colleagues but of the European and even the Chinese population of the Colony. One of his first efforts was to secure the appointment of nursing sisters. The official eye looked askance at the introduction of women into the hospital. After a time official consent was given, but the first ladies appointed had for their qualification the fact that they were members of a religious order. Excellent in many ways, they lacked professional training, and after a brief period Atkinson's advice was accepted and they were replaced by nurses who had been trained in hospitals in England. The hospital administration was gradually improved, and it established a well-earned reputation for its efficiency and excellent work. To this hospital were taken the sailors of the Russian cruiser *Varyag* wounded at the naval battle with the Japanese near Chemulpo. In acknowledgment of the professional services rendered then the Czar presented Mitford Atkinson with a gold cigarette-case ornamented with the Russian coat-of-arms in diamonds.

Mitford Atkinson's medical career can be traced in the reports to the Colonial Government on the Civil Hospital, and on the sanitary condition and administration of the colony of Hong-Kong. Indeed, these reports give the history of the continued sanitary progress of the colony. He held office at the time when plague made its appearance in epidemic form in the colony; the official reports which he wrote on this subject are classics in the literature of the disease. In 1897 he was promoted to the office of Principal Civil Medical Officer, but his connexion with the Government Civil Hospital was not severed. As chief of the Government Medical Department he exercised administrative control over the various civil hospitals of Hong-Kong. In 1903 he was appointed a member of the Executive and Legislative Council of Hong-Kong. In 1912 he retired on pension.

Shortly after the present war broke out, Mitford Atkinson received a commission in the Royal Army Medical Corps, and was granted the rank of major. He was given the task of converting the workhouse and infirmary at Richmond in Surrey into a war hospital. In this work he attained the success he had achieved in Hong-Kong. Possessed himself of indomitable enthusiasm, he had the gift of imparting this quality to others. He won the cordial support and active coöperation not only of the hospital staff but of the patients themselves. In addition, he secured the loyal support of the inhabitants of Richmond, proud of their excellent war hospital. In spite of warnings of a possible breakdown in health, he refused to relax the strain imposed on him by administrative control. Signs of angina pectoris appeared and progressed, and he was invalided out of the

Service, receiving a gratuity for the work he had done. After some months of complete rest he was contemplating again taking up professional work, but he died suddenly on May 23rd.

Certain of Atkinson's medical writings were published from time to time in THE LANCET, a lecture on Plague in 1901, and in 1903 a Case of Septicæmic Plague in a European, and Methylene Blue in the Treatment of Malignant Malaria; in 1909 a Possible Natural Enemy of the Mosquito, and in 1910 a contribution on the treatment of plague and an account of the climate of Hong-Kong. He was a Fellow of the Royal Colonial Institute, the Royal Sanitary Institute, and the Society of Tropical Medicine. He was a keen sportsman and an able exponent in many directions; he ran a dead heat for the amateur 100 yards championship, and played cricket to the end of his life. For a quarter of a century he occupied a prominent position in the medical world of the Far East. At his home all members of our profession were welcome guests when duty or pleasure took them to the colony of Hong-Kong. He married Clara, the eldest daughter of James Eastmond, of Puddington, Devon, and leaves a widow and two sons.

URBAN VITAL STATISTICS.

(Week ended May 26th, 1917.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 17,000,000 persons, the annual rate of mortality was 14·1, against rates steadily declining from 18·5 to 14·3 per 1000 in the six preceding weeks. In London, with a population exceeding 4,000,000 persons, the death-rate was 12·9, or 1·0 per 1000 less than in the previous week; among the remaining towns the rates ranged from 4·5 in Eastbourne, 5·5 in Edmonton, and 7·2 in Ealing, to 22·6 in West Bromwich, 23·1 in Rotherham, and 23·9 in Middlesbrough. The principal epidemic diseases caused 375 deaths, which corresponded to an annual rate of 1·2 per 1000, and included 238 from measles, 53 from whooping-cough, 42 from infantile diarrhœa, 29 from diphtheria, 12 from enteric fever, and 1 from scarlet fever. The deaths from measles were 13 below the average in the four previous weeks, and caused the highest annual death-rates of 3·9 in West Bromwich and in Sunderland, 4·3 in South Shields, 4·5 in Middlesbrough, and 5·8 in Rotherham. The 641 cases of scarlet fever and 1108 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 32 and 52 below the numbers remaining at the end of the previous week. Of the 4579 deaths from all causes in the 96 towns, 146 resulted from violence. The causes of 22 deaths were uncertified, of which 8 were registered in Birmingham, 4 in Liverpool, and 2 in St. Helens.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual death-rate was equal to 16·1, against 15·9 and 17·0 per 1000 in the two preceding weeks. The 358 deaths from all causes in Glasgow corresponded to an annual rate of 16·7 per 1000, and included 35 from measles, 33 from whooping-cough, 5 from infantile diarrhœa, and 1 each from scarlet fever and diphtheria. The 102 deaths in Edinburgh were equal to an annual rate of 16·0 per 1000, and included 10 from measles, 8 from whooping-cough, and 3 from diphtheria.

Irish Towns.—The 151 deaths in Dublin were equal to a rate of 19·7, or 1·3 per 1000 above that recorded in the previous week, and included 5 from infantile diarrhœa, 3 each from measles and whooping-cough, and 1 each from enteric fever and scarlet fever. The 109 deaths in Belfast corresponded to an annual rate of 14·5 per 1000, and included a fatal case of enteric fever and 1 of infantile diarrhœa.

(Week ended June 2nd, 1917.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 17,000,000 persons, the annual rate of mortality was 12·7, against rates steadily falling from 18·5 to 14·1 per 1000 in the seven preceding weeks. In London the death-rate was 11·7, or 1·2 per 1000 less than that recorded in the previous week; among the remaining towns the rates ranged from 3·1 in Aberdare, 4·8 in Ealing, and 6·3 in Merthyr Tydfil, to 20·5 in South Shields, 23·0 in Sunderland, and 31·1 in Middlesbrough. The principal epidemic diseases caused 366 deaths, which corresponded to an annual rate of 1·1 per 1000, and included 245 from measles, 43 from infantile diarrhœa, 41 from whooping-cough, 26 from diphtheria, 7 from scarlet fever, and 4 from enteric fever. The deaths from measles were 7 in excess of the number in the previous week, and caused the highest annual death-rates of 4·9 in Rotherham, 5·0 in Sunderland, 5·2 in South Shields, and 8·6 in Middlesbrough. The 626 cases of scarlet fever and 1061 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 15 and 47 below the numbers remaining at the end of the previous week. Of the 4126 deaths from all causes in the 96 towns, 125 resulted from violence. The causes of 40 deaths were uncertified, of which 6 were registered in Birmingham and 3 each in Stoke-on-Trent, Manchester, and Gateshead, but not one in London.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual death-rate was equal to 16·0, against 17·0 and 16·1 per 1000 in the two preceding weeks. The 382 deaths in Glasgow corresponded to an annual rate of 17·9 per 1000, and included 39 from measles, 38 from whooping-cough, 3 from infantile diarrhœa, and 1 each from scarlet fever and diphtheria. The 102 deaths in Edinburgh were equal to an annual rate of 16·0 per 1000, and included 18 from measles, 6 from whooping-cough, 2 from diphtheria, and 1 from scarlet fever.

Irish Towns.—The 145 deaths recorded in Dublin were equal to an annual rate of 18·9, or 0·8 per 1000 less than that recorded in the previous week, and included 4 from measles, 2 from infantile diarrhœa, and 1 from scarlet fever. The 115 deaths in Belfast corresponded to an annual rate of 15·3 per 1000, and included 2 from scarlet fever and 1 each from enteric fever and measles.

Correspondence.

"Audi alteram partem."

THE LUMLEIAN LECTURES AND MEDICAL RESEARCH.

To the Editor of THE LANCET.

SIR,—The symptomatology of heart disease has undoubtedly its importance in regard to both diagnosis and prognosis, but it is equally true that most, if not all, of the symptoms that may be found attendant upon various diseases of the heart are frequently to be met with in those whose hearts are sound, and, on the other hand, many persons with serious organic heart disease do not complain of any symptoms. One may meet, for instance, with persons with very pronounced aortic regurgitation and others with very definite mitral stenosis (of the pure funnel variety) leading active lives for many years without presenting symptoms. Most of the symptoms connected with the heart are, indeed, of the nature of functional disturbance rather than organic embarrassment, and in my Lumleian lectures (p. 9) I endeavoured to classify them under the headings of (1) malnutrition, defective metabolism, morbid blood stream, functional overstrain as affecting the cardio-vascular muscle; (2) toxic influences, reflex excitation or depression, direct excitation or depression as affecting the cardio-vascular innervation; but I am careful to point out (p. 22) "that functional disturbance is as frequently observed in association with diseased as with healthy hearts and that many of the troubles and some of the catastrophes of cardiac disease are attributable to functional derangements." The criterion in either case, both from the treatment and prognosis points of view, is to be derived only from an estimation of the condition of the heart by physical examination.

I do not for a moment suppose that in practice Sir James Mackenzie would fail to attach all due importance to auscultative and other instrumental diagnosis of heart disease as well as to the consideration of symptoms. He has, as we know, much strengthened our methods in these respects, and his work has met with well-merited appreciation; but the trend of his advocacy at the moment seems to be to invert in order of importance the symptomatic and physical methods of diagnosis, and thus to misguide those who may be less experienced.

When Sir James Mackenzie observes that we should watch each individual case of heart disease throughout his life he speaks but an obvious truth, the only question being as to the opportunity of doing so; and when he adds that the danger lies not in the damaged valve but in the heart not being able to overcome successfully the embarrassment to its work caused by the damaged valve, he states another truism although in inverted order, for the danger is there all the time. It can be foreseen and estimated by careful consideration of the physical signs; when the symptoms of heart failure present themselves compensatory function is already failing. Let me give what I venture to regard as a model report on a case of heart disease for diagnosis and prognosis (the note is not mine, but came before me a few days ago).

An applicant for life assurance is reported to have had two attacks of rheumatism, the last seven years previously; he has an aortic diastolic and a mitral systolic murmur. What are the chances of his longevity? In other words, what is the probable term at which the heart will no longer be able to overcome the embarrassment to its action? In this view the able physician in the case proceeds to point out that the murmurs in either case do not completely replace the valve sound, the heart's action is regular at 78, it shows only a moderate degree of hypertrophy; further, the pulse, although deliberate, has not the collapsing characters of marked aortic regurgitation, and the blood pressure is well maintained at 140. It will thus be observed that we have the valve lesions indicated, the duration of the lesions given, the degree of valve defect shown in the character of the sounds, the power of the heart in overcoming its difficulties shown in the steady, quiet pulse and moderate enlargement, the output of the whole mechanism shown in the normal blood pressure. Is not this a masterly exposition of the facts of the case upon which a sound estimate of the cardiac condition may

be formed and advice given calculated to postpone the symptoms of failure?

Sir James Mackenzie's generous admission that "the older physicians did their work according to their lights as we do ours according to our lights," makes one hopeful that he at least has not yet joined the "reaction-aries," which his reference to the work of Dr. Poynton led me to fear that he might have done.

In this letter I have in mind especially valvular defects and their results upon the heart, which appear to be in question in the present correspondence.

I am, Sir, yours faithfully,

Portland-place, W., June 5th, 1917. R. DOUGLAS POWELL.

To the Editor of THE LANCET.

SIR,—I take second place to no one in my admiration of the work that Sir James Mackenzie has done in connexion with the investigation of diseases of the heart, and were I equally in accord with his controversial methods, it would not be necessary for me to trouble you with this letter. Sir James Mackenzie is a merciless critic from his own point of view of other people's views on cardiac and circulatory disorders, more especially if these happen to belong to what may be styled the old-fashioned type of clinical physician. In the process of pulverising his chimerical opponents he has expended a great deal of energy in flogging tired horses, in tilting at tattered windmills, and in razing to the ground tottering pathological structures which have respectively been flogged, tilted at, and razed to the ground on many previous occasions by many different writers. Clinical heresies no doubt die hard, and it may perhaps be just as well to ensure that they are really dead by killing them more than once! It is, however, quite another matter when in THE LANCET of May 26th Sir James Mackenzie directly challenges Dr. A. Morison to produce evidence of a single instance where he has given with clearness and precision a description of how murmurs can be differentiated to show those that are innocent and negligible from those that imply danger. Furthermore, he asks where, in Dr. Morison's own writings or in the writings of others, the principles for assessing the value of murmurs are indicated. Now, I hold no brief for Dr. Morison, and so hardy a campaigner in the field of cardiac dialectics can safely be left to take care of himself. But I must confess to no small amount of astonishment that hitherto no one has come forward to meet and answer this challenge on behalf of the older school of cardiac clinicians. It is with some diffidence that I feel compelled to undertake the responsibility of making at least some sort of reply to so provocative an inquiry; conscious as I am of my inability to do full justice to the theme, and knowing full well that I shall be accused of attempting to bolster up a lost cause.

Under the influence of Sir James Mackenzie's writings I was under the impression that medical opinion had hardened in the direction of paying relatively less attention to physical signs, including murmurs, and of giving more weight to symptoms and other indications of the condition of the cardiac wall in the investigation and diagnosis of diseases of the heart. Do I understand him aright when I assume that the observations in his letter of May 26th are an attempt to restore the tarnished splendour of physical signs, including murmurs, to their ancient diagnostic glory? I am quite ready to admit that the older writers may have attached too much significance to cardiac murmurs, and in so doing they no doubt neglected other features of greater value in the elucidation of disorders of the heart. Indeed, Sir, in this connexion I should be prepared to quote from authors on diseases of the heart written during the last 50 years material on the significance of murmurs sufficient to fill a whole issue of your valuable paper! I will content myself by quoting two instances which will suffice to illustrate my contention. Is Sir James Mackenzie conversant with the writings of my late chief, Sir William Broadbent? I put it to him that Broadbent's observations on the significance of the presystolic and diastolic murmurs of mitral stenosis are as nearly abreast of modern cardiology as anything that has been written. Again, I would call attention to George Balfour's observations on the mitral systolic murmur associated with "curable mitral regurgitation," and ask if no attempt has been made by past masters of clinical medicine to define the significance of cardiac murmurs? Surely Sir James Mackenzie must admit that, with all their faults, the older generation of clinical physicians did not hesitate to grapple with the interpretation of cardiac murmurs and endeavour to explain their significance. They may not have solved the problem, but at least they attempted to do so.

The tendency in the past to consider the different manifestations of a so-called disease in separate compartments has led to much confusion and error. It is essential to the full comprehension of cardiac as well as of other disorders that disease should be looked upon as a *process* beginning with functional disturbance and terminating in gross structural change. The whole series of events correlated with the progressive degradation of function and structure must be recognised and appreciated in all their bearings before it can be said that we understand the nature of any disease.

I am, Sir, yours faithfully,

Upper Berkeley-street, W., June 4th, 1917. E. H. COLBECK.

SHELL WOUNDS IN CHILDREN.

To the Editor of THE LANCET.

SIR,—During the earlier days of the war many children were wounded by shells, bombs, &c., in the towns and villages at the back of the firing line. To deal with these cases a civilian hospital was established in Belgium, situated at first in a town, and later removed to an adjoining field for greater safety. It was composed of long wooden barrack sheds or huts, with a good operating theatre and X ray instalment, and was staffed with Belgian nurses. Cases were brought in by ambulances from the country round, adults as well as children, sometimes very early, and at other times after a good interval had elapsed since the injury. The conditions of treatment being the same for adults and for children, one was able to compare the results of these two classes of case in their response to the treatment received. Unfortunately, partly from lack of assistance, and partly from absence of the facilities for bacteriological work, many notes of value were not kept.

Although other forms of treatment were tried, ordinary principles of surgery were mainly used, and consisted of—(*a*) prompt localisation and removal of all foreign bodies; (*b*) thorough drainage of wounds before, if possible, acute sepsis had set in; (*c*) daily irrigation of wounds with eusol. A general anæsthetic—viz., chloroform induction and warm open-ether sequence—was used in each case. The following serve to show the type of case treated:—

CASE 1.—Boy, aged 11, admitted with shell wound through back of thigh, completely fracturing the shaft of femur about the middle. The metal lodged in front of the bone. He was admitted within a few minutes of the accident. The fragment was at once located and removed by an anterior incision which was sutured and healed by first intention. Good drainage was established by a rubber tube from behind, and the limb put on a Hodgen splint and daily irrigated with eusol. In three weeks the wound was healed, and there was sufficient union of bone to enable all splints to be removed. The temperature was normal after the first three days, and after his sixth week he left hospital on foot carrying his own bundle.

CASE 2.—Girl, aged 10, with badly comminuted compound fracture of thigh by a shell. She was not seen for 10 days, and the missile had been removed elsewhere. After a mild septic course of about two months union was complete, though with much shortening and no necrosed bone came away.

CASE 3.—Girl, aged 12. A large fragment of shell penetrated the skull in the mid-frontal region. She was brought in at once, bleeding considerably from the median sinus. The metal and loose pieces of bone were at once removed, and had penetrated at least one and a half inches in depth. All injured dura was exposed by clipping away more bone. Some brain matter and hair escaped. The wound was packed with gauze for 24 hours. A cerebral hernia followed about the size of a hen's egg. This was dressed for a week with alcoholic compresses. The hernia disappeared in about six weeks, with no after-symptoms of cerebral injury. The temperature was practically normal throughout.

CASE 4.—Boy, aged 3, with shell wound in buttock near anus penetrating to a depth of about 2 inches (in adults not a favourable position). He was seen after 48 hours and the metal was removed literally wrapped in a piece of his coat. The wound healed in about two weeks. The temperature was rather high, but fell to normal at once after operation.

CASE 5.—Boy, aged 10, was playing with a hand grenade which exploded. He was not seen for 24 hours. He lost part of his thumb and received a compound split in the left tibia and an injury of the right knee opening into the joint. The wounds were trimmed and partly sutured and prolapsed muscle cut away. The knee-joint was irrigated with saline, a piece of cloth coming away. The missile had escaped. The capsule was completely sutured and the external wound closed around a gauze drain down to the capsule. The last I saw of him he was running down the road just under a month from the time of injury and all wounds healed.

Children as a class cannot by any means be considered immune from microbic infection, yet compared with the adults who were treated on exactly the same lines children did not exhibit sepsis to anything like the same degree, and their wounds consequently healed quicker. These children were certainly no cleaner than their parents, and their clothes

were often very dirty. It is possible that the smoothness of a child's skin has a good deal to do with this freedom from severe sepsis, and pathological germs reside in the pores and folds of the skin (which are more marked in adults) rather than in the dust and clothes. Psychological effects of explosives on the minds of the younger children admitted were very slight or absent, and they did not show symptoms of fear during air-raids or bombardments to anything like the same degree as did the adults, perhaps partly from want of realisation. As one more illustrative case the following may be given :—

A woman was walking in the street of a well-known Belgian town and her small child with her. The mother was killed on the spot by a bursting shell, and the child seemed wonderfully unconcerned when I saw it a few minutes later. It was not injured.

Finally, it might be added that hæmorrhage entered into prognosis in children before shock, and one or two cases were lost from that alone.

I am, Sir, yours faithfully,

A. H. FARDON,
Medical Officer in Charge.

Headquarters, F.A.U., B.E.F., May, 1917.

THE ETIOLOGY OF GANGOSA AND ALLIED CONDITIONS.

To the Editor of THE LANCET.

SIR,—In the *Annals of Tropical Medicine and Parasitology*, issued by the Liverpool School of Tropical Medicine, Vol. IX., No. 2, dated June, 1915, a description is given by Dr. Anton Breinl, of the Australasian Institute of Tropical Medicine, of gangosa, or rhinopharyngitis mutilans, and of certain forms of osteitis, periostitis, ulcus tropicum, ulcus interdigitale, and of certain forms of leucoderma. These cases are beautifully illustrated by the most excellent photographs. Dr. Breinl considers gangosa to be a separate disease due to an organism named by him *Cryptococcus mutilans*.

We would like to point out that all the above conditions occur frequently in Fiji, especially amongst the Fijians and half-castes, but also amongst Indians and Europeans who have long resided in Fiji. These diseases always are preceded by primary or secondary yaws, and they yield in their active stages to the same remedies as other forms of tertiary yaws, with which they are frequently associated. Medical men in Fiji, having a very large experience of yaws, invariably regard these manifestations as tertiary stages of frambœsia.

We are, Sir, yours faithfully,

PHILIP HARPER,
District Medical Officer, Fiji.
G. W. A. LYNCH, M.B.,
Chief Medical Officer.

March 5th, 1917.

TRENCH SHIN.

To the Editor of THE LANCET.

SIR,—Lieutenant-Colonel Graham Chambers's contribution in THE LANCET of May 19th to the study of that condition known as "trench shin" is of great interest. Whatever the etiology may be, it appears to be generally agreed that fibrositis is the cause of the pain. I have not had an opportunity of seeing these cases in their early stages, but have been called upon to treat many of them from the third week onwards. In the early cases I should be strongly inclined to use salicylate ionisation, but in those I have met I have found the most beneficial results from the sinusoidal current applied rhythmically (Lewis Jones interrupter) with the legs in Schnée baths. Patients tell me they experience great relief and can rest and sleep much better after the treatment, which is given for 20 minutes at a time on alternate days. No doubt the rhythmical contractions of the muscles favour the circulation and elimination of waste products, and I should expect similarly good results from the condenser arrangement devised by the late Dr. Lewis Jones and described by myself in the *Practitioner*, December, 1916. In this, by means of a motor interrupter, a condenser is alternately charged from the main and discharged through the primary of a coil, the patient being connected to the secondary. The current is applied rhythmically and has the advantage of giving powerful motor contractions with a very small sensory effect.

I am, Sir, yours faithfully,

L. W. BATHURST.

Harley-street, W., June 4th, 1917.

The War.

THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue :—

Wounded.

Capt. F. M. Hughes, R.A.M.C., attached London Regiment.
Capt. G. Thomson, R.A.M.C., attached London Regiment.
Lieut. L. C. G. Bacon, R.A.M.C.
Lieut. T. Burrell, R.A.M.C.
Capt. F. R. Thornton, M.C., R.A.M.C.
Maj. N. J. Bullen, Australian A.M.C.
Capt. E. R. Mackay, Australian A.M.C.

Previously reported Missing, feared Killed, now reported not Missing.

Surg.-Prob. A. G. Lennox-Browne, R.N.V.R.

DEATHS AMONG THE SONS OF MEDICAL MEN.

The following sons of medical men must be added to our lists of those who are reported to have fallen during the war:—

Lieut. A. Mantle, London Regiment, younger son of Dr. A. Mantle, of Harrogate.
Capt. H. E. R. Hamilton, Canadian Railway Troops, elder son of Dr. H. T. Hamilton, of Barnes, London.
Lieut. E. H. Hopkinson, M.C., Cambridge Regiment, second son of Dr. A. Hopkinson, of Withington, Manchester.
Lance-Corp. H. M. Dockrell, Duke of Cornwall's L.I., youngest son of Dr. M. Dockrell, of Cavendish-square, London.
Second Lieut. W. G. M. Britton, Royal Flying Corps, fourth son of the late Dr. J. Britton, J.P., of Strabane, co. Tyrone.
Second Lieut. H. H. Ezard, Royal Flying Corps, elder son of Dr. E. H. Ezard, of Cambridge.

[We are glad to learn from Dr. G. T. Eccles, of Hove, that his son, Second Lieut. H. E. R. Eccles, of the Royal Flying Corps, is not dead, as reported, but is severely wounded, and is now in the Royal Flying Corps Hospital at Eaton-square, London.]

THE HONOURS LIST.

The following awards to and promotions of medical officers, for services in the field or for services in connexion with the war, are announced, on the occasion of the King's Birthday :—

K.C.B.

Col. J. Magill, C.B. (ret. pay); Lt.-Col. P. J. Freyer, C.B., I.M.S., ret.

C.B.

Surg.-Gen. G. Welch, R.N.; Fleet-Surg. J. Menary, R.N.; Temp. Surg.-Gen. Sir W. Macewen, R.N.; Temp. Surg.-Gen. G. R. Turner, R.N.; Col. R. Kirkpatrick, C.M.G., A.M.S.; Col. C. H. Burtchaell, C.M.G., A.M.S.; Col. J. J. Gerrard, A.M.S.; Temp. Col. W. H. Willcox, C.M.G.; Lt.-Col. (temp. Col.) G. W. Brazier-Creagh, C.M.G. (ret. pay), late R.A.M.C.; Lt.-Col. (temp. Col.) H. S. Thurston, C.M.G., R.A.M.C.; Lt.-Col. and Bt.-Col. Sir B. G. Seton, Bart., I.M.S.; Col. D. Wardrop, C.V.O. (ret. pay), A.M.S.; Col. C. R. Tyrrell (ret. pay), A.M.S.; Temp. Col. J. Galloway, A.M.S.; Surg.-Lt.-Col. (Hon. Surg.-Col.) R. J. Reece, H.A.C.; Surg.-Lt.-Col. Sir W. R. Crooke-Lawless, C.I.E. (ret. pay), R. of O. (empld. R.A.M.C.); Maj. and Bt.-Lt.-Col. (temp. Brig.-Gen.) A. C. Geddes, Unattd. List.

K.C.M.G.

Surg.-Gen. Sir A. T. Sloggett, K.C.B., C.M.G., K.H.S.; Surg.-Gen. F. H. Treherne, C.M.G.; Surg.-Gen. T. P. Woodhouse, C.B.; Col. R. N. Campbell, C.B., C.I.E. (ret.), I.M.S.

C.M.G.

Fleet-Surg. G. T. Bishop, R.N.; Col. C. C. Manifold, C.B., I.M.S.; Col. D. M. O'Callaghan, A.M.S.; Col. A. W. Bewley, A.M.S.; Lt.-Col. (temp. Col.) F. J. Greig (ret. pay), R. of O., late R.A.M.C.; Lt.-Col. G. Scott (ret. pay), late R.A.M.C.; Lt.-Col. A. Hosie (ret. pay), late R.A.M.C.; Lt.-Col. (temp. Col.) J. C. Connor, R.A.M.C.; Temp. Lt.-Col. A. D. Milne, East Afr. Med. Serv.; Maj. (temp. Lt.-Col.) R. J. C. Thompson, D.S.O., R.A.M.C.; Col. R. E. Roth, D.S.O., Austr. A.M.C.; Lt.-Col. T. H. Sweeny (ret.), I.M.S.; Lt.-Col. F. F. Perry, C.I.E. (ret.), I.M.S.; Lt.-Col. J. Chaytor-White (ret.), I.M.S.; Lt.-Col. S. B. Smith, I.M.S.; Lt.-Col. J. N. MacLeod, C.I.E. (ret.), I.M.S.; Lt.-Col. D. Harvey, R.A.M.C.; Temp. Hon. Lt.-Col. M. H. Gordon, R.A.M.C.; Maj. P. S. O'Reilly, R.A.M.C.; Maj. G. A. D. Harvey, R.A.M.C.; Temp. Maj. A. D. Reid, R.A.M.C.; Col. R. J. Millard, Austr. A.M.C.; Lt.-Col. W. T. Hayward, Austr. A.M.C.; Lt.-Col. T. E. V. Hurley, Austr. A.M.C.; Col. C. A. Hodgetts, Canad. A.M.C.

C.I.E.

Capt. H. H. Thorburn, I.M.S.

Surgeon-General.

Col. (temp. Surg.-Gen.) W. W. Pike, C.M.G., D.S.O.

Brevet-Colonels.

Lt.-Col. S. L. Cummins, C.M.G., R.A.M.C.; Lt.-Col. (temp. Col.) G. T. K. Maurice, C.M.G., R.A.M.C.

Brevet-Lt.-Colonel.

Maj. P. H. Henderson, D.S.O., R.A.M.C.

Brevet-Majors.

Capt. D. M. Corbett, R.A.M.C.; Capt. (actg. Lt.-Col.) B. Johnson, R.A.M.C.; Capt. H. F. Panton, M.C., R.A.M.C.

D.S.O.

I.M.S.—Lt.-Col. H. J. K. Bamfield; Maj. E. T. Harris; Lt. N. S. Jatar; Capt. A. N. Thomas; Maj. C. H. Watson.

R.A.M.C.—Maj. (temp. Lt.-Col.) D. Ahern; Lt.-Col. (temp. Col.) J. D. Alexander; Temp. Capt. P. H. Babr; Lt.-Col. (temp. Col.) A. W. N. Bowen; Maj. R. H. Bridges; Capt. F. Casement; Capt. (actg. Lt.-Col.) H. K. Dawson; Maj. (temp. Lt.-Col.) B. H. V. Dunbar; Temp. Capt. J. J. Dwyer; Capt. (actg. Lt.-Col.) P. G. M. Elvery, M.C.; Lt.-Col. H. B. Fawcus, C.M.G.; Capt. (actg. Lt.-Col.) A. D. Fraser, M.C.; Maj. G. B. Gask; Lt.-Col. (actg. Col.) J. G. Gill; Lt.-Col. G. H. Goddard; Capt. J. Golding; Temp. Maj. (temp. Lt.-Col.) E. L. Gowlland (late Maj., R.G.A., T.F.); Maj. (temp. Lt.-Col.) G. H. L. Hammerton; Lt.-Col. (actg. Col.) H. Herrick; Maj. (temp. Lt.-Col.) H. C. Hildreth; Lt.-Col. C. H. Howkins; Maj. (temp. Lt.-Col.) W. D. C. Kelly; Capt. H. Lightstone, M.C.; Capt. (actg. Lt.-Col.) A. S. Littlejohns; Temp. Lt.-Col. D. D. Logan; Lt.-Col. (temp. Col.) P. MacKessack; Capt. (actg. Lt.-Col.) G. Mackie; Capt. (actg. Lt.-Col.) R. Magill; Temp. Capt. J. R. Marrack, M.C.; Lt.-Col. E. W. P. V. Marriott; Maj. (temp. Lt.-Col.) J. Matthews; Capt. (actg. Lt.-Col.) C. R. M. Morris; Capt. (actg. Lt.-Col.) K. D. Murchison; Capt. (actg. Lt.-Col.) A. D. O'Carroll; Lt.-Col. (temp. Col.) S. de C. O'Grady; Maj. J. S. Pascoe; Maj. (temp. Lt.-Col.) J. E. Powell; Maj. (temp. Lt.-Col.) T. P. Puddicombe; Lt.-Col. (temp. Col.) M. M. Rattray; Maj. J. D. Richmond; Maj. (temp. Lt.-Col.) H. Rogers; Maj. (temp. Lt.-Col.) D. Rorie; Temp. Capt. (actg. Lt.-Col.) L. D. Shaw; Maj. G. F. Sheehan; Maj. S. B. Smith; Capt. (actg. Lt.-Col.) G. H. Stevenson; Maj. (temp. Lt.-Col.) H. Stewart, M.C.; Capt. (actg. Lt.-Col.) M. R. Taylor; Capt. (temp. Maj.) R. S. Taylor; Maj. J. A. Turnbull; Temp. Capt. R. B. Wallace; Lt.-Col. A. H. Waring; Capt. (actg. Lt.-Col.) A. G. Wells; Maj. (temp. Lt.-Col.) R. M. West; Maj. W. J. Weston; Lt.-Col. E. A. Wraith; Maj. (temp. Lt.-Col.) T. J. Wright.

Australian A.M.C.—Lt.-Col. H. N. Butler; Maj. G. C. Byrne; Maj. G. E. Cole; Lt. Col. (temp. Col.) C. T. C. De Crespigny; Maj. W. A. Fraser; Lt.-Col. (temp. Col.) W. W. Hearne; Lt.-Col. (temp. Col.) R. B. Huxtable; Maj. C. L. S. Macintosh; Capt. A. H. Powell; Lt.-Col. A. H. Tebbutt; Maj. R. W. W. Walsh; Maj. H. L. St. V. Welch.

Canadian A.M.C.—Maj. R. M. Gorsaline; Lt.-Col. W. B. Hendry; Maj. J. S. Jenkins; Lt.-Col. C. F. McGaffen; Lt.-Col. J. D. McQueen; Lt.-Col. C. P. Templeton; Lt.-Col. E. J. Williams.

New Zealand M.C.—Maj. T. D. M. Stout.

South African M.C.—Lt.-Col. R. L. Girdwood; Maj. (acting Lt.-Col.) R. N. Pringle; Lt.-Col. H. W. Vaughan-Williams.

Military Cross.

I.M.S.—Capt. A. N. Dickson.

R.A.M.C.—Temp. Capt. G. O. F. Alley; Capt. L. B. Baird; Capt. J. H. Bayley; Temp. Capt. J. H. Box; Capt. R. A. Broderick; Temp. Capt. J. V. Brown; Temp. Capt. L. G. Brown; Capt. A. E. Bullock; Temp. Capt. E. R. C. Cooke; Capt J. M. A. Costello; Capt. G. Dalziel; Lt. R. Ellis; Capt. W. T. Gardiner; Temp. Capt. N J. H. Gavin; Capt. W. George; Temp. Capt. D. Hardie; Capt. P. Hartley; Capt. A. S. Heale; Temp. Capt. J. T. Hurst; Capt. L. H. W. Iredale; Temp. Capt. A. Jones; Temp. Capt. D. Kelly; Capt. D. R. King; Temp. Capt. G. N. Lorimer; Temp. Capt. J. T. MacKenzie; Capt. J. C. Metcalfe; Temp. Capt. H. J. Milligan; Capt. J. R. Mitchell; Temp. Capt. H. Moore; Capt. R. E. U. Newman; Capt. M. W. Patterson; Temp. Capt. A. S. Plant; Temp. Capt. R. A. W. Proctor; Capt. J. P. Quinn; Temp. Capt. W. K. A. Richards; Capt. D. J. Scott; Capt. C. F. Searle; Temp. Capt. A. D. Sharp; Temp. Capt. H. S. Sugars; Capt. O. Teichmann; Temp. Capt. W. B. Wamsley; Capt. L. T. Whelan; Capt. J. St. G. Wilson.

Australian A.M.C.—Capt. H. W. F. Mitchell; Capt. G. S. Robinson; Capt. C. T. Turner; Capt. F. L. Wall.

Canadian A.M.C.—Capt. A. C. C. Johnston; Lt. (temp. Capt.) C. G. Sutherland; Capt. W. G. Turner; Capt. R. H. M. Hardisty.

New Zealand M.C.—Capt. A. V. Short.

South African M.C.—Capt. R. P. McNeill.

Egyptian Army M.C.—Yuzbashi Wadid Effendi Tanuis Ghusn.

Rhodesian Medical Service.—Surg.-Capt. E. G. Storrs.

MENTIONED IN DESPATCHES.

The names of the following medical officers mentioned in Sir Douglas Haig's despatch are additional to those published in THE LANCET of June 2nd, p. 856:—

Australian Army Medical Corps.—Col. G. W. Barber, D.S.O.; Lt.-Col. (temp. Brig.-Gen.) W. W. Hearne; Lt.-Col. (temp. Col.) R. B. Huxtable; Maj. L. W. Jeffries, D.S.O.; Maj. J. J. Nicholas; Col. A. Sutton, C.M.G.; Maj. A. S. D. Barton; Lt.-Col. H. N. Butler; Maj. G. C. Byrne; Lt.-Col. J. Corbin; Lt.-Col. C. T. de Crespigny; Capt. M. J. Holmes; Capt. (temp. Maj.) A. O. Howse; Maj. J. P. Kenny; Capt. N. E. B. Kirkwood; Maj. E. F. Lind; Maj. G. W. Macartney; Capt. J. McCusker; Maj. C. L. S. Macintosh; Capt. I. Morgan; Capt. A. H. Powell; Capt. S. A. Railton; Col. R. E. Roth, D.S.O., V.D.; Lt.-Col. H. S. Stacy; Capt. H. O. Teague (killed); Lt.-Col A. H. Tebbutt; Maj. C. W. Thompson, M.C.; Maj. R. W. W. Walsh; Maj. H. L. St. V. Welch; Capt. G. C. Willcocks; Lt.-Col. M. I. Williams (died of wounds); Maj. A. M. Wilson.

Canadian Army Medical Corps.—Maj. R. M. Gorsaline; Maj. J. S. Jenkins; Lt.-Col. C. P. Templeton; Maj. A. T. Bazin; Maj. P. G. Bell; Capt. T. H. Bell; Capt. H. Buck; Lt.-Col. K. Cameron; Capt. J. C. Clarke; Maj. C. H. Dickson; Lt.-Col. J. M. Elder; Capt. A. W. M. Ellis; Col. J. T. Fotheringham, C.M.G.; Maj. A. L. C. Gilday; Capt. D. B. Kennedy; Capt. C. Kerr; Lt. (temp. Capt.) A. F. Laird; Capt. W. G. Lyall; Capt. A. McCausland; Capt. R. R. McClenahan; Lt.-Col. C. F. McGuffin; Lt.-Col. J. D. McQueen; Maj. G. S. Mothersill; Capt. H. R. Mustard; Lt.-Col. G. R. Philp; Maj. G. H. Wilson; Lt.-Col. C. F. Wylde.

New Zealand Medical Corps.—Lt.-Col. (temp. Col.) D. J. McGavin; Lt.-Col. J. Hardie-Neil; Maj. T. D. M. Stout; Capt. W. G. Borrie.

South African Medical Corps.—Maj. (actg. Lt.-Col.) R. N. Pringle; Temp. Maj. C. M. Murray.

Indian Medical Service.—Col. C. C. Manifold, C.B.; Lt.-Col. H. J. K. Bamfield.

Supplementary.—Capt. (temp. Lt.-Col.) D. B. Chiles-Evans, D.S.O., R.A.M.C. (killed); Capt. J. R. N. Warburton, R.A.M.C.

The following names of medical officers are mentioned in a despatch received from the Acting Sirdar and Governor-General of the Soudan, dated April 17th, 1917:—

Capt. S. McK. Saunders, R.A.M.C. (senior medical officer); Capt. B. H. H. Spence, R.A.M.C.

FOREIGN DECORATIONS.

Russian.

Order of St. Stanislas, 2nd Class (with Swords).—Fleet-Surgeons R. Hill, C.V.O. (now Deputy Surg.-Gen.), J. A. Moon, D.S.O., J. C. Ferguson, C. M. Beadnell, T. Austen, A. Maclean, D.S.O., H. W. Finlayson, D.S.O., E. C. Cridland, E. A. Penfold, D.S.O., L. Kilroy, H. K. Jones, and J. Stoddart.

Order of St. Stanislas, 3rd Class (with Swords).—Surgeon-Probationers A. G. Bee, G. Bluston, W. A. Turner, and W. E. Heath, R.N.V.R.

Order of St. Anne, 1st Class (with Swords).—Surg.-Gen. M. W. O'Keefe, C.B.

Order of St. Anne, 3rd Class (with Swords).—Staff-Surgeons F. H. Gowans, T. E. Blunt, and J. McA. Holmes, D.S.O.

French.

Légion d'Honneur, Croix de Chevalier.—Lt.-Col. A. E. Le Bel, Canadian, A.M.C.

Croix de Guerre.—Lt.-Col. H. B. Fawcus, C.M.G., R.A.M.C.; Temp. Capt. R. W. P. Jackson, R.A.M.C.; Capt. S. J. Linzell, R.A.M.C.; Col. S. Macdonald, C.M.G., A.M.S.; Temp. Capt. A. G. Maitland-Jones, R.A.M.C; Temp. Capt. V. M. Rich, R.A.M.C.; Temp. Capt. A. G. H. Smart, R.A.M.C.

THE WAR AND MEDICINE IN THE UNITED STATES.

Medical education in the United States during the war will proceed as far as possible on pre-war lines. As the result of a conference of the deans of the medical schools of the United States, held in Washington, it has been decided that it would be inexpedient to alter courses of instruction in order to expedite graduation. It is considered that the existing standards of medical education are better calculated to ensure a regular and adequate supply of competent physicians, however long the war may last, than any modification of prevailing methods. It has been agreed, however, to reorganise medical teaching so far as may be practicable in order to release as many men from the faculties of the medical schools as can be spared for military duty.

Under the title of the Red Cross Supply Service a new organisation has been formed to distribute among American soldiers and military hospitals gifts and supplies from patriotic individuals and relief societies throughout the country. The headquarters will be in Washington, with branches to supervise the collection and preparation of supplies at other large cities. It is hoped that much waste will be eliminated through coöperation with relief societies and systematic methods of purchase and distribution.

In the States there have been conferences of State and Territorial health officers to discuss the war work of the health authorities. In connexion with the sanitation of military and naval camp sites and the hygienic control of camps, it is suggested that the police power of the various jurisdictions might be brought to bear directly on the environments of camps, and so establish a subsidiary control in addition to that of the military authorities, while State laboratories might be made available for the diagnosis and sanitary oversight of infectious diseases among troops. Special precautions will be taken to prevent the introduction of infectious diseases owing to contact between the civilian and military populations.

The pharmaceutical manufacturers are going energetically into the business of supplying the medicines required for the war. Mr. Frank G. Ryan, president of Messrs. Parke, Davis, and Co., has enlisted in the Army and has been detailed on the Council of Defence, a body organised for the purpose of mobilising the industries of the country. This body has comprehensive powers and has already gone to work in a systematic manner. Mr. Ryan is secretary of the committee having the pharmaceutical and chemical section of the work specially in charge. The organisation covers every manufacturer of importance in the country, and each firm has promised to do its full duty. It is estimated that the supplies for hospital service alone will require 40,000 freight cars for transit, and the usual proportion of this material will consist of drugs and chemicals. This will interfere with the regular trade to a considerable extent, manufacturers having unanimously decided that the needs of the army must come first.

HEALTH OF THE MESOPOTAMIAN ARMY.—The War Office has issued a statement to the effect that the incidence of sickness among the men occupied in the Mesopotamian campaign is 60 per cent. less for the first fortnight of May, 1917, than for the corresponding period last year.

OBITUARY OF THE WAR.

ARTHUR TILBURY, M.R.C.S. ENG.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain A. Tilbury, who is reported missing, believed drowned on May 4th, when the *Transylvania* was sunk, was youngest son of John Tilbury, of Oakley, Hants, and brother of Mr. R. Tilbury, M.R.C.S., of 235, Queen's-road, S.E., with whom he was in partnership. Educated at Guy's Hospital, he obtained the qualification of the Conjoint Board (Lond.) in January, 1913, and joined his brother, while he continued to do clinical appointments at Guy's Hospital. When war broke out he was called up as a reservist in the London University O.T.C., and received a commission in the R.A.M.C. After serving at Canterbury for a year he was sent to Egypt in September, 1915. In March, 1917, he came to England on special duty, and it was on his return journey that he met his early death. His loss is keenly felt by his many friends at Guy's Hospital.

LEONARD GEORGE SCUDAMORE, M.R.C.S. ENG., L.R.C.P. LOND.,

LIEUTENANT, ROYAL ARMY MEDICAL CORPS.

Lieutenant L. G. Scudamore, who recently died in camp in England after a few hours' illness at the age of 47 years, was the seventh son of the late Frank Ives Scudamore, C.B. Born in Eltham he spent his early years in Turkey, where his father was stationed. He received his general education in France and Germany, returning to England to study medicine at St. Thomas's Hospital, whence he took the Conjoint diploma in 1891. For the past 15 years he had practised as a colliery surgeon in South Wales and Monmouthshire and was thus engaged when he took up war work. He served first as a civil surgeon at Edmonton Military Hospital, applying later for a commission, which was granted him in June, 1916. He served at various camps in this country, and to his keenness and unsparing devotion to duty his sudden and untimely death is attributed by those who knew him.

At the Edmonton Military Hospital Lieutenant Scudamore proved himself a capable surgeon and agreeable colleague. One who worked with him there writes: "Those of us who were fortunate enough to get behind the barrier of his reserve were able to appreciate the noble heart of the man, the astonishing wideness of his knowledge, his linguistic gifts and caustic humour, and lastly, his great devotion to duty. His self-denying work did not escape the notice of his patients, and it is no exaggeration to say that he was worshipped by the colliery villagers and soldiers among whom he worked."

Lieutenant Scudamore had only recently married Sister Gertrude Able, R.R.C., formerly of the Royal Orthopædic Hospital and now of the Prince of Wales's Hospital for Officers, with whom the greatest sympathy is felt.

JOHN JAMES WEAVER, M.R.C.S. ENG.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain J. J. Weaver, who was recently thrown from his horse at the Curragh Camp and killed, was 54 years of age and son of the late Dr. John Weaver, of Southport. Educated at University College, London, he qualified in 1886, and after a resident appointment at Oldham Infirmary went a cruise in a private yacht in the Mediterranean, when he rendered assistance to the crew and passengers of the wrecked P. and O. *Tasmania* in circumstances of great credit. Two years as house surgeon to the Southport Infirmary followed, and he then settled in practice at Southport. Becoming more and more interested in public work he was appointed to the medical officership of health in 1900. He became chairman of the health committee and an active agent in securing improvements in the sewerage system of the town and in the water- and milk-supplies. He already held commissioned rank as a surgeon with the Territorials, and in April, 1915, accepted a commission in the R.A.M.C., attached to the East Lancs Regiment, with which he served in various parts of England. Quite recently he was appointed chief sanitary officer at the Curragh, where he was killed instantaneously by a fall from his horse.

Outside his public work Captain Weaver was interested in various benevolent institutions in Southport. He was at one time honorary medical officer to the Day Nursery in Boundary-street and to the Girls' Orphanage and Training Home. He was generally known as a good friend to the poor in the town. Captain Weaver was married to Annie Pennington, daughter of the late T. O. Clinning, J.P., of Birkdale, by whom and a daughter he is survived.

JOHN BAILEY TACKABERRY, M.B., B.S. LOND.,

CAPTAIN, INDIAN MEDICAL SERVICE.

Captain J. B. Tackaberry, who died of cerebro-spinal fever in Mesopotamia on March 25th, was second son of the late T. Tackaberry, of Dungannon. Educated at Dungannon Royal School and Trinity College, Dublin, he received his medical training at the Middlesex Hospital, where he qualified M.B., B.S. Lond. in 1909. He held resident posts in the hospital and was assistant demonstrator of anatomy in the medical school before entering the Indian Medical Service, with a high place in the examination in 1911. After serving in India and at Hong-Kong, and receiving promotion in 1913, he was sent out to Mesopotamia attached to a Punjabi regiment. He leaves a widow, who is engaged in voluntary nursing at St. John's Hospital, Sevenoaks, and one child.

THE MIDDLESEX HOSPITAL AS A "MOBILISATION CENTRE."

The War Office have decided to make an immediate but strictly limited trial of the scheme for organising hospital units contained in the pamphlet by Lieutenant-Colonel Sir James K. Fowler, K.C.V.O., on the "Medical and Nursing Services of the Imperial Army," which we noticed last week.[1] Circumstances having necessitated an increase in the hospital accommodation for the armies in the various theatres of war, it has been determined that one of the additional units required may be raised from amongst the medical men educated at a single London hospital who have not yet been able to serve abroad for various reasons, or, having already done so, desire to renew their engagements for a further period. The Middlesex Hospital has been selected for the trial, and Sir James Fowler has undertaken to form a "mobilisation centre" as described in his pamphlet.

This is not to be regarded as in any sense affording a test of the value of the scheme as a whole, which is one obviously intended to come into operation at the outbreak of a war. More than 400 Middlesex men are known to be now, or to have been some time during the war, serving as officers of the Royal Army Medical Corps, and other hospitals have an equally good record. The officers of this new unit will all be Middlesex men, the matron, sisters, and nurses will have been trained at that hospital, and the V.A.D.'s will be selected from families connected with the hospital, but the orderlies will be men now serving with the Royal Army Medical Corps. The unit will be known as the Middlesex No. —— General Hospital. No undertaking will be given that the personnel of this unit be not detached to other units, as the exigencies of the service may render such a proceeding necessary. The unit will be raised for general service and will be sent to any of the various theatres of war at which it may be required. It follows that the officers, nurses, &c., must all be fit for general service, and engagements will be for the duration of the war. No applications from Middlesex men now serving abroad for transfer to this unit will be considered except in special circumstances.

Communications connected with the unit should, in the first instance, be addressed to Lieutenant-Colonel Sir James Fowler, or, in the case of nurses and V.A.D.'s, to the Matron, at the Middlesex Hospital, Mortimer-street, W.

NEW MILITARY HOSPITALS.—The first Plymouth V.A.D. hospital was formally opened by the Mayor in the presence of a large gathering. The hospital contains 200 beds arranged in 16 marquees. The County Territorial Association have placed their buildings at the disposal of the authorities, and these are used for dining- and recreation-rooms and offices. The sum of £3206 has been collected locally towards the cost of the scheme.—Tockington Manor, Gloucestershire, has been fitted up as a military hospital through the generosity of Captain Salmon. It is to be used by the authorities of the Beaufort War Hospital, and was formally opened last week and 20 patients admitted.—On May 16th Miss G. Buller formally opened the new building which is to be an extension of the Crediton (Devon) V.A.D. Hospital. It will provide accommodation for 42 beds, and increase the accommodation in the Crediton Hospital to a total of 72 beds. Mr. Leslie Powne is in medical charge of the institution.—Ashton Court, near Bristol, has been recently opened as a convalescent home for officers, and 70 patients are in residence.—Bathampton House, near Bath, which has been fitted up as a Red Cross hospital, has now been opened. It is delightfully situated and is the second Red Cross hospital in Bath.

PERSONS engaged in the manufacture, purchase, sale, or other dealings in artificial human eyes have been ordered, under the Defence of the Realm Regulations, to send in to the Director of Optical Munitions and Glassware Supply, 117, Piccadilly, W. 1, immediate returns containing particulars of the number, type, and material of all artificial human eyes in their possession or under their control.

[1] The pamphlet, price 3*d*, may be obtained from Messrs. Macmillan and Co., Limited, St. Martin's-street, London.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Gen. Sir Arthur W. May, K.C.B., K.H.P., has been placed on the retired list from June 1st, 1917, at his own request.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. H. E. M. Douglas, V.C., C.M.G., D.S.O., to be temporary Colonel whilst employed as Assistant Director of Medical Services of a Division.

Temp. Major D. P. Kappele (Can. A.M.C.) to be temporary Lieutenant-Colonel while holding appointment as O.C. Can. Cav. Field Ambulance.

Temp. Major W. Hind (Major and Bt. Lieut.-Col., T.F. Res.) to be temporary Lieutenant-Colonel.

Temp. Capt. Ryder P. Nash (Capt., R.A.M.C., T.F.) to be acting Lieutenant-Colonel whilst in command of a Field Ambulance.

Lieut.-Col. A. R. Aldridge, C.S.I., C.M.G., Res. of Off., to be acting Colonel whilst specially employed.

Temp. Major W. R. Dawson to be temporary honorary Lieutenant-Colonel.

Temp. Hon. Major W. I. de C. Wheeler to be temporary Major and honorary Lieutenant-Colonel.

Temporary Captains to be temporary Majors: H. H. Serpell, E. W. Witham, V. J. Blake, F. B. G. Stableford, G. P. Humphery, B. G. Elliott (Major E. Lan. R. (T.F.)), C. Saint-Pierre (Can. A.M. Corps), L. E. Pariseau (Can. A.M. Corps), J. A. H. Forgues (Can. A.M. Corps), J. L. Petitclerc (Can. A.M. Corps), J. Lafleur (Can. A.M. Corps).

W. S. Haughton to be temporary Major.

Capt. O. R. McEwen to be acting Major whilst in charge of a Base Depôt Medical Store.

The undermentioned are granted temporary rank for duty with South African Native Labour Corps: As Majors: T. N. Frood, F. H. Welsh. As Captain: C. A. Kitching, E. B. Israel, W. F. McGlashan, H. Tren, W. J. Calder, W. L. A. Leslie, C. D. Goodenough, G. B. Moffat, L. E. Hertslet, L. P. Booth, T. A. Beddy, M. Ricono, C. J. H. Aitken, J. McLaw, C. G. Todd.

The undermentioned are granted temporary rank whilst serving with Belfast War Hospital: As Lieutenant-Colonel: W. Graham. As Captain: S. J. Graham.

A. C. D. Firth, late temporary Captain, is granted the honorary rank of Captain.

Temporary Lieutenants to be temporary Captains: J. R. Payne, D. MacC. Brown, A. N. Drury, A. A. B. Scott, J. C. Anderson, H. I. Davies, F. W. Davidson, C. Stanley-Clarke, J. A. Vlasto, C. G. Kemp, F. C. Jobson, C. C. Austin, J. Gray, R. L. Ferguson, O. R. Allison, T. M. Bride, A. E. Finney, P. S. Green, W. A. Cardwell, W. W. Wood, F. Shannon, L. Gameson, S. H. Calnek, E. H. Montgomery, H. M. Drake, G. Arthur, D. I. Dakeyne, C. A. R. McCay, E. J. B. Moynihan, H. H. Crickitt, R. H. Balfour-Barrow, G. W. Doran, W. T. Evans, D. M. Smith, J. Manuel, H. Joslen, W. Spiteri, J. A. H. Vanderwert, A. P. MacMahon, W. M. Stewart, R. Lindsay, J. W. Macfarlane, F. R. Martin, J. N. Cruikshank, A. Davidson, J. B. Fisher, T. R. Fulton, G. Kirkhope, T. H. V. King, P. G. Foulkes, S. G. Harrison, V. C. James, J. A. Tobin, R. G. Gillies, A. A. Greenwood, W. B. Knobel, W. D. Newcombe, L. G. Jacob, A. N. Haworth, D. Kennedy, W. C. Gore, P. A. Dargan, D. W. Smith, E. H. Eastwood, N. B. Capon.

A. Stephens, late temporary Lieutenant, to be Honorary Lieutenant.

E. Kaye Le Fleming to be temporary Honorary Lieutenant whilst employed with the British Red Cross Hospital, Netley.

Temp. Hon. Lieut.-Col. C. H. Fagge (Major, R.A.M.C., T.F.), having resigned his appointment, relinquishes his temporary commission.

Officers resigning their commissions: Temp. Maj. S. W. Woollett, and is granted the honorary rank of Major. Temporary Captains: M. E. Robinson, A. T. Roberts, C. J. Butler, J. A. Gibb, C. S. Crichton, T. L. Wormald, A. H. Butcher, G. W. Stone, H. C. Thorp, J. R. McVail. Temporary Lieutenants: L. F. McDowell, W. T. Little, H. R. Hodgkinson, M. D. Baker, W. Anderson, F. H. Simpson, W. H. C. Romanis, G. A. Francis, C. D. Hatrick, R. H. Titcombe, T. F. Collins, H. Lewis, D. J. Roantree, A. E. A. Carver, A. Smirthwaite, R. E. J. St. J. Griffin.

SPECIAL RESERVE OF OFFICERS.

Capt. R. Magill to be acting Lieutenant-Colonel whilst in command of a Field Ambulance.

Lieut. on probation J. A. W. Cullen is confirmed in his rank.

To be Lieutenants: A. B. Black, W. Brown, N. S. Bruce, S. N. Dyke, R. G. Battersby, L. W. Hughes, and J. J. Mulvey, from the Glasgow University Contingent, O.T.C.; F. O. Taylor, J. H. Wiseman, R. L. Robinson, and O. St. L. Campion, from University of London Contingent, O.T.C.; W. W. Newton, J. J. A. Scott, H. G. V. Mence, and F. J. Harvey, from Birmingham University Contingent, O.T.C.; T. C. Murphy, J. Rowland, H. Chadwick, H. Gainsborough, and L. Gill.

TERRITORIAL FORCE.

Major (acting Lieut.-Colonel) W. D. Watson relinquishes his acting rank on ceasing to command a field ambulance.

Lieut.-Col. C. E. Douglas, from T.F. Reserve, to be Lieutenant-Colonel.

Major W. McCall to be Acting Lieutenant-Colonel while commanding a field ambulance.

Capt. R. P. Nash is seconded whilst holding a temporary commission in the R.A.M.C.

Capt. A. G. R. Foulerton to be temporary Major.

Capt. (temp. Major) A. C. H. McCullagh to be Acting Lieutenant-Colonel while commanding a field ambulance.

Capts. S. Acheson and J. W. Heslop, from T.F. Reserve, to be Captains.

Lieuts. C. A. E. I. Brownlee and J. McG. H. Reid to be Captains.

To be Lieutenants: L. H. Callendar, F. J. E. China, and R. C. Davie.

Capt. E. P. I. Coke relinquishes his commission on account of ill-health, and is granted the honorary rank of Captain.

Capt. R. J. Irving relinquishes his commission on account of ill-health.

TERRITORIAL FORCE RESERVE.

Col. A. V. Clarke to be Colonel.

INDIAN MEDICAL SERVICE.

The relinquishment of the temporary rank of Lieutenant by Narayan Mahadev Bodas and Tanguturi Janakiramiah has been approved by the King.

COLONIAL MEDICAL SERVICES.

West African Medical Staff.—The death is reported of Mr. L. Doudney, medical officer, Nigeria (Northern Provinces), and of Dr. T. Ryan, medical officer, Gambia, who was drowned at sea by enemy action. Mr. C. E. S. Watson, Senior Medical Officer, has been promoted Provincial Medical Officer, Nigeria (Northern Provinces). Dr. J. C. M. Bailey, Temporary Lieutenant, R.A.M.C., has been appointed Senior Medical Officer, Nigeria (Southern Provinces). Dr. A. E. Horn, Senior Medical Officer, has been transferred from the Gambia to Nigeria (Northern Provinces), and Mr. E. C. Adams, Senior Medical Officer, from the Gold Coast to the Gambia. Dr. R. W. Gray, Senior Medical Officer, Nigeria (Southern Provinces), has retired on pension, and Dr. G. G. P. Beckett, Temporary Lieutenant, R.A.M.C., medical officer, Gold Coast, has resigned his appointment. Dr. G. F. Darker has ceased to be temporarily re-employed as Medical Officer, Nigeria (Northern Provinces), and Dr. H. G. F. Spurrell has ceased to be temporarily employed.

The following officers, whose services have been placed at the disposal of the Army Council, have been given temporary commissions in the Royal Army Medical Corps: A. C. Parsons, C. L. Ievers (Gold Coast), E. A. Charters, and W. G. Cobb (Nigeria). The following have been temporarily lent to other administrations: A. E. Horn, T. H. Suffern (Nigeria), G. J. Keigwin (Gold Coast) to the Provisional Civil Administration, German East Africa; H. F. Hamilton (Gold Coast), P. A. Clearkin, J. McK. Clark, J. M. O'Connell (Sierra Leone) to the East Africa Protectorate; J. Currie (Nigeria) to the Uganda Protectorate; and H. E. Arbuckle (Sierra Leone), and E. J. Quirk (Nigeria) to the Nyasaland Protectorate. T. M. R. Leonard, G. H. Gallagher, T. E. Sandeman, E. Gibson, and C. Mackey (Nigeria) are on military duty in East Africa.

DEATHS IN THE SERVICES.

Brigade-Surgeon Augustus Frederick Elliot, A.M.S. (retired), at his residence, Exmouth, on May 25th, in his eighty-fourth year. He joined the Army Medical Service in 1861, served in the Ashanti War of 1873 and 1874, and was present at the capture of Coomassie. He retired in 1884 with the honorary rank of brigade-surgeon.

Medical News.

UNIVERSITY OF LONDON.—At examinations held recently the following candidates were successful:—

THIRD (M.B., B.S.) EXAMINATION FOR MEDICAL DEGREES.

Charles Vincent Boland, St. Bartholomew's Hospital; Clement Capton Chesterman, University of Bristol; Hetty Ethelberta Claremont, London School of Medicine for Women and St. George's Hospital; Raghunath Ganesh Dani, University College Hospital; Philip Oswald Ellison, St. Bartholomew's Hospital; Thomas Stenner Evans, University College, Cardiff, and St. Mary's Hospital; John William Heekes, Charing Cross Hospital; Jerusha Jacob Jhirad, London School of Medicine for Women; John Isaie Keen (honours, distinction in surgery), Charing Cross Hospital; Frank Alexander Knott, Guy's Hospital; Edward Eric Lightwood, Westminster Hospital; John Edward George McGibbon, University of Liverpool; George Alex Sheridan Madgwick, London Hospital; Ferdinand Molina, St. Thomas's Hospital; Victor J. E. C. del S. Perez y Marzan, University College Hospital; Pinthu Sai, St. Thomas's Hospital; Basil Sampson, Guy's Hospital; Raghunath Dadoba Shirvalkar, University College Hospital; Philip Smith, Guy's Hospital; Daniel Jenkin Thomas and John Herbert Thomas (honours, distinction in surgery), University College Hospital; and Lotty Welhermann, London School of Medicine for Women.

B.S. EXAMINATION *(for Students who graduated in Medicine in or before May, 1904).*

Sidney Forsdike, University College Hospital.

The following candidates have passed in one of the two groups of subjects:—

Group I.—Hannah Katherine Alton, King's College Hospital and London School of Medicine for Women; Elizabeth Labrey Ashby, University of Birmingham; Margaret Stote Glen Bott, Dorothy Trevor Daintree, Alice Mary Ley Greaves, and Rosalie Jobson, London School of Medicine for Women; William Arthur Edward Karunaratne, University College Hospital; Sinnethamby Muttiah, London Hospital; Morris Schwartz, University College Hospital; and Ellen Sylk, London School of Medicine for Women.

Group II.—Thomas Anwyl Davies, St. Thomas's Hospital; Susan Alfreda Finch, London School of Medicine for Women; Harry Mainwaring Holt, University of Leeds; and Henry Cecil Jennings and Cyril Valentine Pink, St. Thomas's Hospital.

HILDEN CONVALESCENT HOSPITAL, BELFAST.—This institution, the first hospital established in Ulster under the joint auspices of the British Red Cross Society and the Order of St. John, was organised by the Joint Ulster Committee of these two societies, and was opened on May 23rd by Mrs. Harold Barbour, whose generous contribution to the funds made the inception of the hospital possible. Admirably situated in a well-wooded park in the southern outskirts of Belfast, the main hospital, a private mansion, has accommodation for 50 wounded soldiers, with an annexe containing 80 beds. Sir Robert Kennedy, K.C.M.G., D.L., chairman of the Ulster Joint Committee of the Red Cross and St. John, who presided, was supported by the Lord Mayor of Belfast, the High Sheriff of Belfast, and General Sir William Adair, K.C.B., D.L. Sir John Byers said there were two valid reasons for the foundation of such a beautiful hospital—first, it occupied a niche of its own amongst all the other hospitals in the city of Belfast that had to do with wounded soldiers, inasmuch as it was concerned mainly with convalescents, while its existence would help the Minister of Pensions in his scheme for the up-building of the wounded soldier.

A DEVONSHIRE CENTENARIAN.—Mrs. Mary Honeywill died recently at Marybank, Beeson, in her 101st year.

Lieut.-Colonel (Temp. Colonel) Oliver Long Robinson, C.M.G., R.A.M.C., has been appointed an honorary physician to the King, vice the late Surgeon-General Sir W. Taylor, K.C.B., M.D.

Lord Rhondda is announced to address a meeting at the Queen's Hall, London, on Wednesday next, at 5 P.M., on the progress made during the past six months in the campaign against venereal disease. Sir Alfred Keogh will speak to the military side of the question. The Lord Mayor of Liverpool and Mrs. Creighton will also speak, the latter representing the women's point of view. Application for tickets should be made to the secretary of the National Council for Combating Venereal Diseases, Avenue Chambers, Southampton-row, W.C.1.

PLYMOUTH ASYLUM.—The Plymouth borough council has adopted a scheme for the enlargement of the borough asylum. It provides accommodation for 440 additional patients, at an estimated cost of £100,000. The Board of Control has just informed the local authorities that it is prepared to consider the plans for this extension.

MEDICAL TREATMENT OF THE DISCHARGED AND DISABLED.—The Executive Committee of the National Medical Union, at a meeting held on May 29th, resolved that the following expression of opinion be sent to Mr. Barnes, the Pensions Minister: "That if it be, as reported, the intention of the Government to limit the choice of medical attendance for discharged disabled uninsured soldiers and sailors to medical men on the Insurance panels, it is a gross invasion of their right to freedom of choice, and an injustice to the large body of medical men not engaged in Insurance practice."

THE LATE MR. W. WHITWORTH.—William Whitworth, M.R.C.S., L.S.A., died at his residence, St. Agnes, Cornwall, on May 14th, in his sixty-fourth year. The deceased, who succeeded to his late father's practice, had practised in St. Agnes for 30 years, and was district medical officer and honorary medical officer to the convalescent home. He did much good work for the establishment of the local nursing association, and the Miners' and Mechanics' Institute owes its present building largely to his efforts. His portrait was presented to him by the local residents in 1903. He leaves a widow and three sons, two of whom are in the Army.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

DUNSTAN, ROBERT, M.R.C.S., L.S.A., has been appointed Acting Medical Officer and Public Vaccinator for the Paignton and Marldon District of the Totnes (Devon) Union.

HEATH, CHARLES, J., F.R.C.S. Eng., Consulting Aurist to the Metropolitan Asylums Board Infirmary for Children.

LOCKET, THOMAS WOOD, M.A., M.B., B.C. Camb., Acting Medical Officer and Public Vaccinator for the Lacock District of the Chippenham (Wilts) Union.

MASON, P. J., M.B., Ch.B. Birm., Certifying Surgeon under the Factory and Workshop Acts for the Tipton District of the county of Stafford.

SALT, ARTHUR PHILIP, M.R.C.S., L.R.C.P., Medical Officer to Totnes Workhouse, and Medical Officer and Public Vaccinator, Totnes and Harberton Districts of the Totnes (Devon) Union.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

BIRMINGHAM CITY EDUCATION COMMITTEE.—Temporary Assistant School Medical Officer. Salary £300 per annum.

BODMIN, CORNWALL COUNTY ASYLUM.—Female Junior Assistant Medical Officer. Salary £200 per annum, with board, &c.

BOOTLE BOROUGH HOSPITAL.—Junior House Surgeon. Salary £170 per annum, with board, &c.

BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN.—Female House Physician. Salary £150 per annum, with board, &c.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at East Wemyss, in the county of Fife.

Births, Marriages, and Deaths.

BIRTHS.

FISHER.—On May 31st, at Belgrave-crescent, Edinburgh, the wife of Edward F. Fisher, M.B., F.R.C.S., Temporary Surgeon, R.N., of a daughter.

HAYES.—On May 30th, at Fallowfield, Edgbaston, the wife of Captain L. C. Hayes, R.A.M.C., of a son.

TIRARD.—On June 5th, Mabel (*née* Dury), wife of Lieutenant N. S. Tirard, R.A.M.C., of a daughter.

MARRIAGES.

ALDERSON—PASTEUR.—On June 4th, at St. Andrew's, Wells-street, by the Rev. W. Harry Roberts, M.A., Captain Gerald Graham Alderson, F.R.C.S., R.A.M.C., son of Mr. and Mrs. John Alderson, of Newcastle-on-Tyne, to Marguerite Norah, elder daughter of Colonel W. Pasteur, A.M.S., and Mrs. Pasteur, Chandos-street, Cavendish-square.

WARBURTON—O'HAGAN.—On June 2nd, at St. John's Church, Pendlebury, by the Rev. T. Dale Jones, M.A., Gilbert Bertram Warburton, M.B., Ch.M., F.R.C.S. Eng., second son of the late Samuel Warburton, of Bolton, to Edith Eveline Maureen, younger daughter of Charles O'Hagan, of co. Meath, Ireland.

DEATHS.

BARTLET.—On May 27th, at Birkfield, Ipswich, J. H. Bartlet, M.D., aged 87.

HILL.—On June 2nd, at The Brow, Clevedon, Somerset, Walter J. Hill, M.R.C.S., L.R.C.P.

IRVINE.—On May 22nd, at Abergeldie, Torquay, J. Pearson Irvine, C.E., O.R., only and beloved son of the late J. Pearson Irvine, M.D., F.R.C.P. Lond., Mansfield-street, Cavendish-square, London, W., and Mrs. Irvine (late of Cromartie), Torquay.

VAUGHAN.—Killed in action on May 22nd, R. W. Vaughan, M.B., M.R.C.S., L.R.C.P. Lond.

WINKFIELD.—On June 3rd, at Beaumont-street, Oxford, Alfred Winkfield, M.A., F.R.C.S., aged 79 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

"BANTING."

IT is interesting at the present time, when certain foods are practically excluded from our diet, to turn to William Banting's "Letter on Corpulence, addressed to the Public" (2nd edit., 1863). Mr. Banting, an undertaker by trade, *not* a physician as stated in an American medical dictionary, had found himself growing excessively fat and had sought advice in all directions without finding it. An article in the *Cornhill Magazine* on "What is the Cause of Obesity?" offered no tangible remedy for corpulence, and Banting went the rounds of the consultants without discovering anyone who could relieve him of his too, too solid flesh, till one day, seeking a remedy for increasing deafness, he lighted on an F.R.C.S., "an eminent aural surgeon," whose name he suppresses in the first two editions of his famous pamphlet, and was told to avoid starchy and saccharine matter. He felt better for the new regimen from the first and very soon was the much-talked-of "cure" of the hour. At his house in St. James's-street he was visited by obese persons of fashion, and to them, as well as to the suffering and presumably overfed public, he communicated his dietary. This is remarkable in view of our present shortage of the foods which he avoids—namely, bread, butter, milk, sugar, beer, and potatoes; it forms a vivid picture of the alcoholic and still almost Lucullan fare which was held to constitute short commons just 54 years ago.

"For breakfast," says Mr. Banting, describing his daily menu during his treatment, "I take four or five ounces of beef, mutton, kidneys, broiled fish, bacon, or cold meat of any kind except pork; a large cup of tea (without milk or sugar), a little biscuit, or one ounce of dry toast. For dinner, five or six ounces of any fish except salmon, any meat except pork, any vegetable except potato, one ounce of dry toast, fruit out of a pudding, any kind of poultry or game, and two or three glasses of good claret, sherry, or Madeira—champagne, port, and beer forbidden. For tea, two or three ounces of fruit, a rusk or two, and a cup of tea without milk or sugar. For supper, three or four ounces of meat or fish, similar to dinner, with a glass or two of claret. For nightcap, if required, a tumbler of grog—(gin, whisky, or brandy, without sugar)—or a glass or two of claret or sherry. This plan leads to an excellent night's rest, with from six to eight hours' sound sleep. The dry toast or rusk may have a tablespoonful of spirit to soften it, which will prove acceptable."

Grand total about 21 ounces of solids and 30 of liquids, *plus* the grog or the "glass or two," but no quantity need be rigidly adhered to provided the forbidden foods be eschewed.

CRÊPE BANDAGES.

Alfred Velpeau, a Paris surgeon of the middle of the nineteenth century whose name is associated with the introduction of the crêpe bandage, may well be regarded as a benefactor by those who were formerly dependent for elastic pressure on bandages containing caoutchouc. The crêpe bandage, while of constant width, is highly elastic in its length, and is light, cleanly, and well ventilated. Formerly manufactured exclusively in Geneva, crêpe bandages may now be obtained in this country. The Norwich Crape Company (1856), Limited, has sent us samples of bandages and of various qualities of bandage material, all of good make. These bandages may be used with added comfort to the patient to replace the ordinary inelastic bandage under all kinds of conditions. The initial expense is largely compensated by the length of time which the crêpe bandage lasts when carefully used.

TREE "SURGERY."

THERE has recently appeared in the public press an interesting account by Mr. Henry Wood, special correspondent of the United Press of America with the French armies, of the efforts made to restore trees mutilated by Germans in their retreat. There were thousands of trees, he reports, that the close pursuit of the French prevented the Germans from completely cutting down; instead, the tree-killers cut off a circle of bark around the trunk, which with a few days' exposure to the sun would be sufficient to kill peach, plum, apple, apricot, and cherry trees that had been half a century attaining their productiveness. These trees, of course, presented an easy problem to those skilled in arboriculture, and such experts were quickly summoned into counsel on the regained French territory. The wounds were bound up like the wounds of a soldier, and thousands of Army surgeons and Red Cross ambulance drivers and stretcher-bearers assisted in the work. The circle where the bark had been cut away was first covered with a grafting cement and the entire wound bandaged—often with bandages that had been prepared for human limbs. So great was the number of trees that had to be dressed in this way that the entire available supply of grafting preparation was quickly exhausted.

Where the trees had been entirely cut or sawn down the protruding stumps were trimmed, and the exudation of the sap was prevented by clay or cement dressings, while branches from the upper portion of the trees which showed signs of life activity were grafted on many of the severed stumps. To-day, Mr. Wood tells us, these grafts are in full leaf and blossom. The roots appear to have been entirely saved by this process, and years have been saved in restoring the cut-down orchards of France. "Tree surgery" is no new art, and for several years, particularly in America, the practice of preserving trees that have been injured by disease or accident has been successfully carried out by filling stumps with cement. The protection of severed vegetable tissues with wax, tar, and other substances has been long used in horticulture and arboriculture. The principles governing the "surgery" of plants are, in many respects, similar to those which appertain to human surgery.

LONDON CHILDREN'S COUNTRY HOLIDAYS.

THOSE responsible for the Children's Country Holiday Fund are proposing to adopt the same policy this year as last—viz., to select a moderate number of specially ailing children and send them away for the usual fortnight. Railway companies are still willing to charge the half single fare for the children, but the increasing difficulty of finding country homes under existing food conditions and the dearth of available London visitors is likely considerably to reduce the numbers who can safely be sent away. The inspection before leaving London, both in regard to vermin and to possible infection, is so carefully conducted that medical attention is not very frequently required in the country. Under these conditions no hesitation need be felt in assisting this most beneficent work, which is in line with the widespread effort not to let the child-life of the country suffer from the effects of the war if the contingency can in any way be avoided.

THE MEDICAL HISTORY OF THE UNITED STATES.

Now that American doctors, surgeons, and nurses are arriving in Great Britain and France there will naturally be increased interest in all that concerns them and their history. Much information will be found in the voluminous American Medical Directory published by the American Medical Association at Chicago (fifth edition, 1916, $10). Another useful book is "The Cyclopædia of American Medical Biography," containing the lives of eminent deceased physicians and surgeons from 1610 to 1910. This book was compiled by Dr. Howard A. Kelly and published in two volumes by Messrs. W. B. Saunders Company, London and Philadelphia, in 1912. Other useful particulars are contained in "Who's Who in America," published in London by Kegan Paul, Trench, Trübner, and Co., Limited, and in Chicago by A. N. Marquis and Co. Useful information regarding the Colleges and Universities will be found in the reports of the Commissioner of Education issued by the Department of the Interior and published by the Government Printing Office, Washington, and in the Official Directory of Professional Education in the United States, published by the University of the State of New York. A good source of information is "The World Almanac and Encyclopedia," issued by the Press Publishing Company, Pulitzer Building, New York, of which copies can be obtained in London.

A USEFUL POCKET MEDICINE-CASE.

Messrs. Burroughs Wellcome and Co. have put up in handy form a collection of useful drugs and first-aid appliances enclosed in a case, 6 × 3½ × 1 in., which can readily be carried in the pocket. The drugs include quinine, acetylsalicylic acid, cascara, bismuth salicylate, ginger essence, and soda-mint. The first-aid outfit contains adhesive and court plaster, pleated bandage and gauze, jaconet, eye-brush and safety-pins, a capsule of iodine tincture, and soloids of potassium permanganate. The whole forms a useful pocket vade-mecum for any doctor, dresser, or nurse at home or abroad. The case is called No. 131 "Tabloid" Medicine Pocket-case, and costs from 13*s.* 6*d.* to 15*s.*, according to the material of the case.

T. O.—There is no generally accepted method of classifying cases of pulmonary tuberculosis, but a study of recent reports of tuberculosis officers shows a large proportion who use the Turban-Gerhardt classification, generally with some little modification of their own. Few, if any, have followed the suggestion of giving a separate estimate of extent of disease in the two lungs. Clinicians generally find the need of adding to a classification based upon physical signs some indication of symptoms. Turban always supplemented his original Groups I., II., and III. with the letters F, f, a to indicate febrile, sub-febrile, and afebrile, and + or − to denote the presence or absence of bacillary sputum. Inman's distinction of resting-febrile, resting-afebrile, walking-afebrile cases is the simplest form yet suggested of recording functional ability.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
MEETINGS OF SECTIONS.

Tuesday, June 12th.

MEDICINE (Hon. Secretaries—Charles R. Box, W. Cecil Bosanquet): at 5.30 P.M.
Lecture (with lantern demonstration):
Major Aldo Castellani: Tropical Diseases to which the Allied Troops are Exposed in the Balkanic Zone.

Wednesday, June 13th.

OPHTHALMOLOGY (Hon. Secretaries—Kilmore W. Brewerton, A. W. Ormond): at 8.30 P.M.
Annual General Meeting.—Election of Officers and Council for 1917-1918.
Discussion:
On "The Etiology and Treatment of Iritis" will be opened by the President (Mr. Lang).
Other Speakers:—Sir Anderson Critchett, Lt.-Col. Elliot, Dr. John Eyre, Dr. Lakin, Mr. Herbert Fisher, Mr. J. G. Turner, Mr. Colyer, Mr. Frank Kidd, Mr. G. H. Pooley, &c.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.
FRIDAY.—5.30 P.M., Papers:—Read for Father G. Greggio (Belgian Congo): The Treatment of Yaws and Other Diseases in the Belgian Congo. Dr. R. T. Leiper: A Note on the Integument of the Bilharzia Miracidium.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.
MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.
TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.
WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.
THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.
FRIDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.
SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

ROYAL INSTITUTE OF PUBLIC HEALTH, Lecture Hall of the Institute, 37, Russell-square, W.C. 1.
Course of Lectures and Discussions on Public Health Problems under War and After-war Conditions:—
WEDNESDAY.—4 P.M., Lecture IX.:—Lieut.-Col. Sir John Collie, M.D.: The Management of Neurasthenia and Allied Disorders in the Army. Followed by a discussion.

METEOROLOGICAL READINGS.

(*Taken daily at 8.30 a.m. by Steward's Instruments.*)
THE LANCET Office, June 6th, 1917.

Date.	Rainfall.	Solar Radio in Vacuo.	Maximum Temp. Shade.	Min. Temp.	Wet Bulb.	Dry Bulb.	Remarks.

,, 5	...	113	81	57	61	71	Fine
,, 6	...	110	67	55	56	60	Cloudy

Other information which we have been accustomed to give in these "Readings" is withheld for the period of the war.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.*

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

Offices: 423, STRAND, LONDON, W.C. 2.

MANAGER'S NOTICES.

ALTERATION IN THE PRICE OF "THE LANCET."

INCREASED war expenses and cost of production necessitate an increase of the price of THE LANCET. Commencing with the new year, the price was raised to 8*d*. The rates of subscription remain as revised in October.

INLAND.			
One Year	£1	10	0
Six Months	0	16	0
Three Months	0	8	0
COLONIES and ABROAD.			
One Year	£1	12	6
Six Months	0	17	6
Three Months	0	8	9

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C. 2.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C. 2, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION is published in time to catch the weekly Friday mails to all parts of the world.

ADVERTISEMENT RATES.

Books and Publications ... ...
Official and General Announcements
Trade and Miscellaneous Advertisements and Situations Vacant ... ... } Five lines and under ... ... 4*s*. 0*d*.

Every additional line, 6*d*.

Goulstonian Lectures
ON
PARATYPHOID INFECTIONS.

Delivered before the Royal College of Physicians of London

BY CHARLES HEWITT MILLER,
M.D. CAMB., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN, LONDON HOSPITAL; PHYSICIAN, VICTORIA HOSPITAL FOR CHILDREN; LATE MAJOR (TEMP.), R.A.M.C.

LECTURE III.*

MORBID ANATOMY.

THE number of recorded post-mortem examinations is not large and the accounts of various authorities differ considerably.

Stolkind[1] has collected 100 cases from the literature and his own experience. He divides them into six main groups: 1. 12 cases in which the changes were similar to those of typhoid fever. 2. Over 25 cases of acute gastritis and acute gastro-intestinal catarrh. 3. 10 cases with lesions similar to dysentery. 4. 10 cases of transition forms (swollen follicles and Peyer's patches). 5. In many cases the lesions were the same as in septicæmia. 6. In some cases no lesions were found in the gastro-intestinal canal.

Job and Hirtzmann[2] describe two autopsies on patients who had paratyphoid A fever: 1. Intense congestion of the last metre of the ileum; Peyer's patches not altered; mesenteric glands swollen; spleen enlarged, but not friable. 2. Intestines congested; spleen diffluent.

Job and Ballet[3] describe one case of paratyphoid B and three of paratyphoid A: 1. Paratyphoid B, slight swelling of lymphatic tissue of the small intestine; mesenteric glands swollen; spleen enlarged. 2. Paratyphoid A, one ulcerated Peyer's patch; deep ulceration of sigmoid and rectum; mesenteric glands enlarged and swollen; spleen enlarged and diffluent. 3. Paratyphoid A, Peyer's patches a little raised and pink; mesenteric glands swollen. 4. Paratyphoid A, general congestion of small and large intestine and appendix. They conclude that the paratyphoid organisms have little affinity for Peyer's patches.

Sawasaki describes three varieties: 1. A septicæmic type with swelling of mesenteric glands and parenchymatous degeneration of organs. 2. An enteric type, with swelling and ulceration of the lymphatic tissue of the small and large intestine. 3. Dysenteric types.

Dawson and Whittington, in their series of 17 autopsies, found ulceration of the small and large intestine in 7; ulceration of the large intestine in 2; ulceration of the small intestine in 6; there were also ulcers in the appendix in 2 cases. The spleen was mentioned as being large and soft in 4 cases, large and firm in 3, having abscesses in it in 2, normal in 1 case and small in 1. In these series the ulceration of the intestines was more definite and more extensive than in many cases reported.

Rathery in his large series limits his post-mortem observations to the intestines. In the small intestine he found ulceration of Peyer's patches as in typhoid; there was also very great degeneration of the glandular cells of the mucosa. In a convalescent patient there were atrophic changes in the small intestine and scarring of Peyer's patches. In one case there was a hypertrophic condition of the valvulæ conniventes. In the colon ulcers large and small were found and a hypertrophic condition of the mucosa.

From these various accounts it is possible to say that in paratyphoid infections—

1. The lesions may be the same as in typhoid fever.
2. The large intestine is more commonly ulcerated than in typhoid fever.
3. The intestines may be acutely inflamed throughout their length but the lymphatic tissue may escape.
4. There may be no change at all in the intestines.

MORTALITY.

The mortality is difficult to calculate exactly. For practical purposes the mortality in the vaccinated should be kept distinct from that in the unvaccinated. But with such figures as can be obtained it becomes evident that it is a mistake to regard the paratyphoid fevers as being necessarily mild diseases. For example, Rathery had 74 deaths in his series of cases of paratyphoid B fever. This works out at 6·79 per cent. In Osler's series of 1500 typhoid fever patients the mortality was 9·1 per cent. Willcox gives the mortality for paratyphoid in the Mediterranean Force as 3 to 5 per cent.

There are so many varying factors in the collection of statistics of this kind that it would be unwise to dogmatise about them. It is enough to say that paratyphoid fever is a serious disease and is fatal in an appreciable number of cases. According to Rathery the most frequent cause of death is some cardiac complication. But it is not clear whether he includes under this heading toxæmia and asthenia, which other observers agree are common forms of death. Perforation and peritonitis, hæmorrhage and severe pulmonary conditions will account for most of the other fatal cases.

PROGNOSIS.

Briefly, in those protected by inoculation the prognosis is good. In the uninoculated the prognosis is very far from being good. In the first two years of the war paratyphoid fevers were much more severe than typhoid fever. At that time nearly every man was protected by inoculation against typhoid fever, but paratyphoid vaccination had not come into force. It used to be said that paratyphoid B was a mild disease. I do not think that would be said now. Rathery gives a mortality percentage of 6·79 in his large series of paratyphoid B fevers. Percentages, even of a large series such as his, are not trustworthy. I do not think it can be said that paratyphoid A fever is any milder than paratyphoid B. Certainly the paratyphoid A infections from Gallipoli that I have seen were not mild.

In comparing the statistics of mortality in paratyphoid fever with those of typhoid fever it has to be remembered that the latter are based on observations made on the general population, whereas the statistics of paratyphoid mortality are derived from observations made on soldiers. It is known that typhoid fever is more dangerous in women, in the elderly, and in the obese. It would not be surprising if the paratyphoid fevers were also more dangerous in the same manner. The prognosis for paratyphoid fevers in a civilian population would certainly be worse than among soldiers. These considerations emphasise the statement that paratyphoid fevers could be a great danger to the community, greater, perhaps, than is realised at present.

DIAGNOSIS.

The diagnosis should be made by the clinician and the bacteriologist working together. It is possible for the diagnosis to be made on clinical grounds alone, and the type of the infecting organism may be guessed accurately if the case occurs in the neighbourhood of other cases of known bacteriological infection. When, for example, there is an outbreak of paratyphoid B fever, and a patient is seen who has the symptoms of enteric fever, his infecting organism may be correctly named. But this is not diagnosis. The clinician can diagnose enteric fever, but he must turn to the bacteriologist and ask him which member of the group is at work. If the bacteriologist is unable to find any evidence of infection, is the diagnosis to be given up? The answer is an emphatic "No." The bacteriologist has many difficulties to contend with, and these bacilli do not always behave according to the rules laid down for them.

A diagnosis made on good clinical evidence must stand, but it must not be more definite than "enteric fever." Sometimes only negative laboratory results are obtained during the illness. The positive results may then be obtained during convalescence.

(A.) FROM CLINICAL SIGNS.

The clinical signs on which the diagnosis can be made have been described under the various types of the disease that have come under my observation. No matter under what mask the identity of the disease may hide, it is usually discovered as the illness proceeds. The more obviously "enteric" type of signs and symptoms often appear after the initial form of the disease is a week old. In other cases suspicion may be aroused by the atypical behaviour of the patient, and the bacteriologist can then give valuable assistance. But such cases are likely to be overlooked unless there are paratyphoid patients already under observation. A patient may begin a typical lobar pneumonia and later develop spots, an enlarged spleen, and

* Lectures I. and II. were published in THE LANCET, May 19th and June 2nd, 1917.

[1] Stolkind: Proc. R. Soc. Med., Nov. 23rd, 1915.

[2] Job and Hirtzmann: Bulletin et Mém. de Méd. Soc. des Hôpit. de Paris, vol. xxxvii., iii. S.

[3] Job and Ballet: Ibid., xxxix., iii. S.

diarrhœa; or a patient with an inflamed knee-joint may be suspected of gonorrhœa unless similar joints have been recently seen among paratyphoid patients. The enteric group of symptoms and signs may be present or the majority of them may be absent.

The rash, the spleen, the intestinal disturbance are all of importance but not essential. The most important clinical phenomenon is the slow pulse with a rising temperature. Captain H. F. Marris, R.A.M.C., has described an interesting diagnostic point. He has administered a hypodermic dose of atropine, gr. 1/33, to some of these patients. His results show that if the pulse-rate is quickened the infection is not enteric, but if it remains the same or becomes slower the chances are that the infection is of the enteric group.

The spots themselves are not good diagnostic evidence. There are so many possible causes of skin eruptions, especially in soldiers, that great care is needed in deciding their nature. The spleen also is enlarged in so many diseases that by itself an enlargement is of little value. Intestinal disturbances were so common in Gallipoli that a man without diarrhœa was an exception. But a history of a few days' diarrhœa followed by constipation is a very suggestive point.

Differential diagnosis between the two paratyphoids has not been possible except by bacteriological methods. At one time it seemed possible that jaundice might be a special feature of one and not of the other. But this idea had to be given up. Paratyphoid B was the more frequent cause of jaundice in patients coming from France and paratyphoid A in those coming from the Mediterranean area.

Colitis again went through a similar vogue. I am not concerned now with the speculations as to the original cause of colitis in paratyphoid. It is enough to record that the worst and most numerous cases of paratyphoid colitis were paratyphoid A from Gallipoli; on the other hand, in France paratyphoid B is responsible for the bulk of the paratyphoid colitis.

As regards severity there is nothing to choose between the two infections. It would seem that paratyphoid A is over and done with more satisfactorily than paratyphoid B. The latter tends to be more refractory. Also paratyphoid A adheres more closely to the typhoid pattern than does paratyphoid B. But none of these points can be in any way considered diagnostic of one or the other.

(B.) LABORATORY DIAGNOSIS.

I approach this part of the subject with hesitation for bacteriological examinations are outside my province. The methods employed in the laboratory may be briefly enumerated.

1. *Hæmoculture.* This is the best single method of diagnosing a paratyphoid infection. A positive result may be obtained in the early days of the infection. Campbell[4] says that between the second and sixth days is the best period for finding the organism in the blood. The disadvantage is that the patient may not come under observation until the organisms have retired from the blood.

2. Isolation of the organism from the *urine* is a valuable aid when a positive result is obtained. When the result is negative, as it often is, nothing is proved.

3. Isolation of the organism from the *stools* is a more complicated process. The stools in most cases will contain the organism at some period of the disease. Negative results do not in themselves negative the diagnosis. Positive results have to be proved very carefully before they can be accepted. The disadvantages of the examinations of the stools are considerable. There may be organisms present, such as *B. pyocyaneus* and *B. fæcalis alkaligenes*, which make the isolation of the paratyphoid organisms a difficult matter. The fæces may contain so many allied strains of bacilli that an organism may be isolated that is culturally one of the enteric group, but fails to comply with the serological tests. It is not enough to find a culturally positive paratyphoid organism in the stools. The organism should be agglutinable with its own specific antiserum. If it does not agglutinate, it is difficult to know how to decide in the matter of diagnosis. If the patient has clinically enteric fever, and a paratyphoid organism of this type is found in the stools, is it justifiable to say that the patient has paratyphoid fever? It has been found that these inagglutinable bacilli do in some cases agglutinate in the course of time. The bacillus should also be tested with the patient's serum. Sometimes the bacillus agglutinates with the patient's serum, but not with the stock serum. In this case I think it is justifiable to say that the bacillus is the pathogenic organism of the disease from which the patient is suffering, but until it is found to agglutinate with a specific serum it cannot be named.

All these investigations demand time and elaborate methods to differentiate the organisms. It is enough for me if the patient has enteric fever and a culturally positive paratyphoid bacillus is isolated from the stools, for in all probability a definite bacteriological result will eventually be obtained. These organisms are apparently very highly specific, and there may be different strains that give the same cultural tests but differ as regards agglutination.

4. *The Agglutination Tests.*

It is outside the scope of a clinical study to deal with the disputed points with regard to the agglutination reactions of the patient's serum. Looking at the question from without, it is obvious that there are two factors that create difficulties.

First, there are two principal methods of testing the agglutinating power of a patient's serum, the microscopic and the macroscopic. It is said that these two methods may give the same results or they give different results in an examination of the same patient.

Secondly, the agglutinating power of a patient's serum is, of course, greatly affected by protective inoculation. The agglutinins derived from the vaccination persist for a different length of time in different individuals. Some of those who use the microscopic method state that febrile conditions due to other causes, such as sepsis, can alter the agglutinating property of a patient's serum.

Lastly, there are undoubtedly inagglutinable strains of paratyphoid organisms, and strains that do not agglutinate until many subcultures have been made.

A person who has been adequately inoculated within a year should have agglutinins in his serum. An uninoculated person who has contracted an enteric fever should have agglutinins in his serum. To neither of these statements can be added the words "absolutely without exception." What is the value, then, of the agglutination test in adequately inoculated persons in whom an enteric fever is suspected?

Dreyer and Ainley Walker[5] have answered this question very decidedly. They have described their technique of employing exact quantitative methods in performing agglutination tests by means of standardised agglutinable cultures. They claim that their method overcomes the difficulties introduced by protective inoculation.

"All doubtful febrile cases, of however short duration, occurring in inoculated persons require a quantitative determination of their agglutinin titre for typhoid and paratyphoid bacilli on three or more successive occasions at a few days' interval before the presence of typhoid or paratyphoid infection can be excluded."

"The rise and subsequent fall in the agglutinin titre are in many cases so definite that the diagnosis could never be in doubt."

"The maximum agglutinin titre of active typhoid or paratyphoid infection occurs between the sixteenth and twenty-fourth day, most frequently between the eighteenth and twentieth day."

It is claimed for their method that a diagnosis can be made when no means will reveal the nature of the infection. But the results also emphasise the importance of having special wards for the admission of such cases as P.U.O., influenza, and trench fever until their disease can be diagnosed as enteric or not enteric.

But their methods and results have not been universally accepted, and the question is one on which more will have to be heard before it can be considered settled.

C. J. Martin and W. G. D. Upjohn have called attention to a peculiarity that may be observed in the serum of those who have been inoculated against typhoid. In the early days of the disease infection with one of the paratyphoid organisms stimulated the production of typhoid agglutinins only, and it was not until as late as the third to the fifth week that the titre of the infecting organism rose to 1 in 100.

It is probable that further observations by bacteriologists will throw light on this subject of agglutination and its interpretation, but at present the question is not settled and

[4] Campbell: Journal of R.A.M.C., 1910., xxvi.

[5] Dreyer and Ainley Walker: THE LANCET, Sept. 2nd, 1916.

is not ready for dogmatic statements to be made about it. As an aid to diagnosis at a time when the clinician requires help agglutination is not of much value. A phenomenon which is best seen on the twentieth day or later is not as useful as the isolation of the organism from the blood or excreta.

5. Blood Counts.

It is possible that a very valuable aid to diagnosis may be obtained from an examination of the cells of the blood, particularly by making a differential count of the white cells. The red cells are usually diminished and the resulting anæmia may be severe. But this anæmia is most pronounced in the later stages of the disease and for many reasons does not give any help in making a diagnosis.

It has been stated frequently, but rather vaguely, that in paratyphoid infections there is a diminution in the total number of white cells with a relative increase in the lymphocytes, and that there is a diminution of eosinophiles in the acute stage followed by an increase during convalescence. It would be of the greatest value if these statements could be made more definite with actual figures to support them. The blood counts should be done periodically all through the illness and convalescence in both inoculated and uninoculated persons.

Walker Hall and Adam [6] have published an account of their observations of differential leucocyte counts in enteric and dysenteric convalescents. Their results are full of promise for this means to become a valuable diagnostic measure. They did not observe the eosinophilia that has been described, but they did not attach much importance to this absence, as it may have been due to the coexistence of an amœbic infection. They observed that there was a greater number of eosinophiles in the blood a few weeks after a triple vaccination (typhoid and paratyphoid) than after a pure typhoid inoculation.

But they found that when agglutinin present in the blood was due to inoculation a normal leucocyte count was obtained, while if the agglutinin was due to infection the typical leucocytosis or polynuclear leucopenia associated with the causal organism would be found.

If a differential leucocyte count will decide whether agglutinins are due to inoculation or infection, many of the bacteriologist's difficulties of diagnosis will be removed. Further, such an examination can be done in a short time and the result known when diagnostic aid is required.

But when all is said and done, it cannot be too strongly insisted upon that for practical purposes, in the acute illness, the diagnosis has to be made on clinical grounds. The bacteriologist may be able to give assistance. But if his results are negative, the clinical diagnosis stands. It is true that it cannot be more close than a diagnosis of the enteric group. But that is enough for treatment and for the prevention of the spread of infection. Even if the clinician has eventually to change his opinion, there will have been less harm done than if a positive paratyphoid patient had not been isolated until the diagnosis was certain.

In the stage of convalescence, in the detection of carriers, and in diagnosing "suspects" the matter is more clearly the province of the bacteriologist.

TREATMENT.

No useful purpose would be served by giving a detailed account of treatment. In the pyrexial stage of enteric fever of paratyphoid origin the usual lines of treatment of typhoid fever should be followed. The following are a few points of treatment based on my cases.

Hydrotherapy in various forms is strongly recommended for high fever, but of all measures of the sort I know of none so efficacious and so little disturbing to the patient as tepid sponging properly carried out. It is the most easily and generally used method of treatment not only for high fever but for restlessness and delirium, for the promotion of sleep, and for improving the general condition of the patient.

As regards general hygiene it is essential that the mouth should have proper attention. Antiseptic alkaline mouth-washes are to be preferred to any other. Those containing glycerine should be avoided. The flow of saliva should be promoted. This can be best accomplished by giving chewing gum and by adding such things as rusks and biscuits to the diet, so that the patient can bite and chew.

[6] Walker Hall and Adam: THE LANCET, Sept. 16th, 1916.

Diet.—I do not consider that a strict milk diet is either essential or desirable. Many adults dislike milk; it is difficult to keep the mouth in good order if nothing but milk is taken, and the curd of milk can make a very tough mass in the intestine in these cases. Variety of diet is greatly to be preferred, and it should be of such a nature that the residue will be neither bulky nor irritating. Solids that are easily digested and leave little residue may be employed with safety—with greater safety in many cases than milk. Meat extracts are valuable in stimulating gastric digestion, but must be avoided when there is diarrhœa. By promoting the salivary and gastric secretions much may be done to nourish the patient safely and satisfactorily. It is most essential that the patient should drink plenty of water; small drinks taken frequently are best. A liberal amount of sugar should be given.

The Bowels.

In the severe cases a simple enema was given regularly whether the bowels were open or not. In milder cases liquid paraffin at night, followed, if necessary, by Epsom salts in the morning, was a satisfactory method of treating constipation. When diarrhœa was troublesome, a regularly given saline wash-out of the colon gave the greatest relief. It could be followed three hours later by a starch enema. At the same time the diet has to be revised, and all possible causes of intestinal irritation removed. Arrowroot flavoured with port satisfied any desire for food, and water in plenty would make up for fluid lost. Distension was treated with enemata, calomel, and pituitrin. It was assumed that peristalsis is less dangerous than stagnation.

In the dysenteric cases, apart from any specific treatment by emetine, the treatment of diarrhœa was difficult. Few of these cases received benefit from the administration of saline purgatives; these measures apparently have their best results at the onset of the illness.

The milder cases were given a mixture of castor-oil and chlorodyne which was found to act satisfactorily. In the severe cases, after trying various methods, I found that opium and astringents acted best. Colon washes with saline or boracic were very beneficial; I found no improvement follow the use of colloidal silver solutions. After the wash a starch enema could be given, especially when a few hours' sleep were necessary.

It was found that in all cases of dysentery after the initial stage, a heaped teaspoon of bismuth carbonate taken in the early morning assisted the recovery. It is very important to prevent a convalescent dysenteric from becoming constipated. Liquid paraffin was invaluable in the later stages of the disease.

Collapse from diarrhœa was treated by the administration of fluid by mouth, by rectum, under the skin, and into the peritoneal cavity. The very slowly given saline injection per rectum is, I think, the most satisfactory method when it can be used. Alcohol is also valuable, and camphor injections are of assistance in an emergency. Strychnine I consider harmful and digitalin useless.

In jaundice the irritation of the skin can be eased by local applications, but particularly by the administration of thyroid extract.

In the stage of convalescence attention has to be paid to the diet and bowels. It is very important that the patient should take active exercise as soon as he feels equal to it.

Intestinal antiseptics were disappointing. Chlorine water, solution of potassium permanganate, β naphthol did not seem to have any effect. Better results were obtained from a proprietary preparation with a phenol basis. It had the effect of deodorising the stools and in some cases banished the infecting organism. But it is impossible to say if the organism was banished permanently. The greatest need is for an antiseptic that will disinfect the gall-bladder. It has been said that urotropine has this power, but the statement lacks proof. But as urotropine is of great value in freeing the urinary tract from infection its use might with advantage become more general.

Vaccine Treatment.

I cannot speak from personal experience of any benefit obtained by vaccine treatment, but in the experience of others satisfactory results have been obtained.

Rathery and his colleagues speak very definitely of the results obtained in the treatment of paratyphoid B, which they claim constitute a clear proof of the favourable action

of vaccines. They have obtained positive results, doubtful results, and negative results. The positive results were recognised clinically by an improvement in the patient's general condition, by a lowering of the temperature, by a decrease in the size of the spleen, and by polyuria. The treatment was not used in the early period of the war, during which the cases were more severe; nor was it used in cases of severe asthenia, great splenic enlargement, and coma. But it was used in all other severe cases. They had no accidents or disasters. They give it as their opinion, which is supported by figures, that vaccinotherapy is a useful aid in treatment.

Further observations are necessary before a definite and conclusive statement can be made. But I do not think that anyone would hesitate to say that vaccination has been proved to be more advantageous to the individual as a preventive than a curative measure.

PREVENTIVE INOCULATION.

The question of the value of preventive inoculation can only be decided when all the statistical material has been collected. At the present time it is only possible to give personal opinions and impressions. For my own part, I can be definite about its value. If any evidence were necessary to establish the value of antityphoid inoculation against typhoid fever, the relative fewness and mildness of the cases of typhoid fever in this war would convince all honest-minded men. It has been suggested by Labbé that anti-typhoid inoculation gives a certain measure of protection against the paratyphoid infections. I cannot agree with this suggestion judging from the cases I have seen, and I find that Rathery and his colleagues are very definite in their statement that antityphoid inoculation, even when repeated four times, gives no protection against *B. paratyphosus B.*

Since the triple (T.A.B.) vaccination came into force the number of cases of paratyphoid fever admitted to Netley has decreased appreciably. This feature is of doubtful value, as the Gallipoli campaign has come to an end. But more important is the type of case. It will be admitted that the descriptions of cases and the temperature charts shown indicate that paratyphoid fever can be a very serious disease. In fact, in 1915 it was more often serious than slight. Nowadays it is rare to see a patient with para-typhoid fever who is seriously ill. For six months I have not seen a patient who caused any anxiety. The difference is so great that the enteric wards are now considered the dull part of the hospital, a very great contrast to their condition in the autumn of 1915.

On the other hand, a fair number of men become infected, and though they are not seriously ill they remain in an unsatisfactory, debilitated condition for a long time; but I think that the slowness of the convalescence is attributable as much to the strain of warfare as to the paratyphoid infection. It is noticeable that in all manner of diseases and wounds it takes longer to restore a man to the full vigour of good health than it did in the early days of the war. But this is a complex problem and outside the scope of my subject.

There are two possible disadvantages with regard to para-typhoid inoculation apart from the temporary malaise of the reaction. The first is of great importance and has already been mentioned. The protection of inoculation has so altered the appearance of the disease that it may not be recognised. When one is accustomed to look for a severe condition dangerous to life it is possible that a bad cold in the head will not arrest attention, and yet in the latter other symptoms suggestive of a mild enteric fever may be seen if a proper examination is made. It is probable, then, that one of the results of inoculation will be an increase in the number of undiagnosed mild cases and a proportionate number of undetected carriers.

The second disadvantage is one that will be gladly seized upon by the antivaccinationist. It is possible for a man to have had a very mild attack and remain infected or to be a carrier without any suspicion being raised that he has the infection upon him. If such a man is inoculated he may develop an attack of paratyphoid fever immediately after the inoculation. In the words of the antivaccinationist, the inoculation gave the man the disease, which is quite true as far as it goes; for by lowering the man's resistance for a time the inoculation caused the infection to get the upper hand Such cases have occurred, but they are very rare, and the ill-ness is trivial and runs a short and mild course. In one case, that of an orderly in an enteric ward, one injection of typhoid vaccine was followed by a mild febrile condition, which was found to be paratyphoid B (Chart 1, p. 748).

The duration of the protection given by vaccination varies considerably. Agglutinins may be present in the blood of typhoid-inoculated individuals for many years after inoculation. But in many cases they are on the wane at the end of two years. Paratyphoid vaccination apparently does not give so long a period of protection. Agglutinins begin to disappear at the end of one year or a little later. If agglutinins are to be taken as the measure of immunity, it would appear proper to repeat the inoculations every twelve months.

MODES OF CONVEYANCE OF INFECTION.

1. Personal contact seems to be a method by which the infection of paratyphoid is directly spread. Several instances have occurred in my experience that are incapable of explanation in any other way. I have heard also of small epidemics that are attributed to this manner of infection. The infectivity of paratyphoid organisms is greater is this respect than is that of typhoid. Costa[7] has described two small epidemics that were due to direct infection.

The Carrier.—Intermediate Transmitting Agencies.

2. The main source of infection is the carrier. Carriers will be found in any army that takes the field. Carriers have been found in civilian life that have caused repeated local epidemics. More of these have been reported in continental countries than in England.

Torrens and Whittington have remarked that paratyphoid A fever did not appear in France until British troops from India arrived on the Western front. I did not notice any paratyphoid A infections coming from France during the first year of the war. There had been plenty of cases of paratyphoid B fever from France, but the first case of para-typhoid A fever occurred in a wounded man admitted on Oct. 1st, 1915.

Gallipoli produced a large amount of paratyphoid infection. Paratyphoid B fever was at its height on the peninsula in September and October, but in November paratyphoid A was the more common infection.[8] The conditions at Gallipoli were such that intestinal diseases were rife, and there was every conceivable condition present to assist the dissemination of infected matter. The carriers played the most important part, assisted by intermediate agents, such as flies, dust, and contaminated water. The conditions of existence were favourable to the propagation of disease, for the men were war-worn, exhausted, cramped in a restricted space, and subjected to bad climatic conditions. Sarrailhé and Clunet found that the conditions which favoured the spread of camp jaundice were fatigue, cramping in a confined space, and unfavourable climatic conditions.

The number of intermediate transmitting agencies could be multiplied, but the following have been proved to be of the greatest importance.

1. Flies can spread the disease, both by carrying infected material on their feet, and by ingesting the organisms and passing them out in their excreta. Graham-Smith,[9] in his book "Flies and Disease," writes:—

> The observations which have been quoted show that flies, if suitable opportunities of visiting infected material occur, may carry and distribute organisms of this type for several days. No instances of infection by flies have yet been recorded.

Faichnie[10] in 1909 published the results of experiments which proved that bacteria ingested by the larvæ of flies might be present in the alimentary canal of the adult. He proved this point with regard to *B. typhosus* and *B. para-typhosus A.* The possibility of the contamination of food by flies is so obvious that the part played by the fly in the dissemination of enteric bacilli need not be questioned. Further, good results have followed measures taken by sanitary officers to exterminate flies.

2. Dust can obviously be a method by which infected particles can gain access to the human body. Of the many plagues of Gallipoli, dust-storms were by no means the least.

3. Contaminated water and food will be the final vehicle of infected material to the human subject. Levine and

[7] Costa: Bull. et Mém. de Soc. Méd. des Hôpitaux de Paris, xxxvii., iii. S. [8] Archibald and others: Loc. cit.

[9] Flies and Disease (Non-blood-sucking Flies). Cambridge Public Health Series. 1913. G. S. Graham-Smith.

[10] Journal of R.A.M.C., 1909, xiii., 672.

Eberson [11] have described a small epidemic that was due to the imperfect treatment of milk bottles which had been contaminated by a convalescent paratyphoid patient.

The Problem of the Carrier.

But however numerous are the possible intermediate agents in spreading paratyphoid infection, it has to be remembered that the real cause of infection is the infected human being. In the acute stage of paratyphoid fever precautions are taken to limit the possibilities of dissemination. In the case of the carrier the danger is greater, because it may not be suspected. A carrier may be an individual in perfect health who can mix freely with his fellows. In communities where there is good sanitation and water drainage the dangers of the carrier are lessened. But even in these circumstances epidemics have been traced to an unsuspected carrier. In barracks, camps, and billets the danger from a carrier is greatly increased, and measures have to be taken to prevent the possibility of the contamination of food and water and to protect the individual by raising his resistance to the infection.

The carrier is usually an individual who has had a recognisable attack of enteric fever, but some of the cases are so mild that they are not suspected. These mild cases are the most dangerous from the point of view of the sanitary officer, and they are probably becoming more numerous. Carriers are of different sorts. The majority are those individuals who pass the organisms in their stools. The gall-bladder is commonly a nest for enteric organisms, and there may be periodical discharges of enteric-laden bile into the intestine. Some of these "gall-bladder" carriers have chronic cholecystitis, and they may have recurrent symptoms which may call attention to the nature of their condition. The most dangerous carrier of all is the male urinary carrier. The fæcal carrier may be expected to pass his infective material into a proper latrine whenever it is possible; the urinary carrier will have a much wider range of action.

The carrier is not only dangerous to others, but he is living in danger to himself. At any time he may develop acute symptoms of paratyphoid fever. It only needs some lowering of resistance by fatigue, shock, wounds, gassing, and even inoculation against any infection for the auto-infection to become severe. Such considerations make it impossible to calculate the incubation period of the disease from observations made on troops in the field.

There does not seem to be any time limit for the carrier. In the case of cholecystitis quoted above the patient had contracted his original infection 16 years before, and I have heard of a similar case with a 50 years' interval.

It is difficult to be certain that a patient who has recently had paratyphoid fever is free from infection. There may be many weeks, and even months, in which the examinations of the stools are negative. Thus one convalescent who remained in hospital for the treatment of other conditions had one positive stool on Oct. 7th and another on Feb. 7th; there had been six negative examinations in the interval. On another occasion, during a spell of hot weather, nearly all the convalescents whose stools had been negative for some time had a positive result.

It is obvious that the carrier is one of the most difficult problems of military hygiene. It is certain that when the organisms are found in the excreta a patient is dangerous and must be segregated. But when they are not found, even over a long period, it is not certain that the man is free from infection. Prolonged segregation and repeated examinations are the only measures that can be taken, and they do not give absolute security.

CONCLUSION.

I will conclude by saying that in our campaign against paratyphoid infection we must aim at personal hygiene, good sanitation, preventive inoculation, segregation of carriers, and, on the part of the clinician, early diagnosis.

I wish to acknowledge my indebtedness to the British Red Cross Society for their kindness in permitting me to use the notes on the patients in their hospital. I also desire to thank Surgeon Lieutenant-Colonel Sir Warren Crooke-Lawless, Commandant of the British Red Cross Hospital, Netley, for giving me the opportunity of seeing these patients as well as for many valuable suggestions, and my colleagues, Major H. L. Tidy and Captain H. A. F. Wilson, for their coöperation and assistance.

AMPUTATIONS CONSIDERED FROM THE ARTIFICIAL LIMB POINT OF VIEW.

BY THOMAS OPENSHAW, C.B., C.M.G., M.S. DURH., F.R.C.S. ENG.,

LIEUTENANT-COLONEL, R.A.M.C.; CONSULTING SURGEON, EASTERN COMMAND; SURGEON TO THE LONDON HOSPITAL.

I VENTURE with all diffidence to state my opinions on the relative merits of the various amputations from the artificial limb point of view.

The Upper Extremity.

With regard to the upper extremity, it is possible to fit an artificial limb to any part. One finger or the thumb of the natural hand is more useful than any apparatus. If only the thumb or one finger is left, artificial fingers or an artificial thumb can be fitted, so that the patient has something to which he can oppose the remaining digit.

Amputation of the wrist-joint should not be done if it is at all possible to leave any portion of the hand, for it gives too long a stump for the proper application of an artificial hand. It is necessary to put the artificial wrist-joint at the end of the natural wrist-joint, and this brings the hand too far away from the elbow, and much power is lost.

For officers or patients engaged in clerical pursuits, a new wrist-joint should be made by removal of one and a half inches of the radius and ulna, for to this joint an artificial hand can be fitted, so that the flexion and extension movements are converted into flexion of the interphalangeal joints of the index and middle fingers. This operation shortens the forearm and increases the power of the flexors of the elbow, and replaces the hand as efficiently as is at present possible. The best site for amputation of the forearm is one where the bones are divided at the lower end of the middle third of the forearm, for this gives a powerful useful stump, not too long, and capable of full pronation and supination.

A forearm stump where the ulna measures three-and-a-half to four inches from the tip of the olecranon is often exceedingly difficult to fit with an artificial forearm bucket. The stump repeatedly slips out of the forearm bucket. As the supinator longus, the extensor muscles, and the flexors are useless, these should be removed in order to produce a flat surface upon which the upper and anterior edge of the forearm bucket can rest. This is especially necessary if the forearm muscles are large. If not more than two inches of the ulna (measured from the tip of the olecranon) can be left, the amputation should be performed above the condyles of the humerus.

Amputation at the elbow-joint should never be performed as an operation of election, for it is difficult, though not impossible, to fit an artificial arm to the stump. If it is imperative that the amputation should be through this joint, the condyles must be removed, for if left it is impossible to accurately fit an arm-socket unless it be laced up the whole length of the front, which considerably weakens it.

The best site for amputation of the arm is one between a point one and a half inches above the elbow-joint on the one hand, and three inches below the fold of the axilla on the other, and an endeavour should always be made to divide the humerus between these two points.

It is difficult to fit an artificial limb to a stump which projects only one inch below the fold of the axilla, but it is still more difficult to fit one where the stump does not project at all.

With regard to the shoulder, it is easier to fit an artificial limb to an amputation where the head of the bone has been completely removed than it is to fit one to an amputation through the surgical neck of the humerus. But, in spite of these difficulties, one should always remember that it is possible to fit an artificial limb to any amputation of the upper extremity.

At the shoulder-joint, by means of a moulded leather cap, an artificial arm is adjusted to the body. Considerable space should be allowed between the arm and the chest wall by flattening the inner surface of the arm, so as to facilitate dressing. By adjustable straps and wires, the movements of the opposite shoulder can be utilised to bend the elbow of the artificial arm, and by a similar arrangement, passing round the chest and down the artificial arm to the thumb, the latter can be moved by abducting the opposite arm.

It is interesting to observe that, in spite of the endeavour of the patient to make the utmost use of an artificial arm, nature constantly asserts the usefulness of the remaining member. If the left arm is lost above the elbow there will be a constantly increasing tendency to use the right arm for everything. This is also noticeable to an increasing extent where the right arm has been lost, for the patient will become left-handed and use his left hand more and more wherewith to perform every function.

The Lower Extremity.

Before passing on to a consideration of the amputations for the lower extremity, let me remind you that in all cases, no matter where the site may be, it is essential that the nerve trunks should be cut as short as possible, and that the end of the stump should be covered with a loose movable non-adherent skin-flap.

With regard to the lower extremity, if the amputation has been of the digits and the bone is well covered with the scar on the dorsum, an artificial boot can easily be fitted, and the patient walks well.

A guillotine amputation through the centre of the tarsus should always be looked upon as a temporary measure, to be replaced by a Syme's amputation as soon as the patient has recovered from the effects of the sepsis and can tolerate a further operation.

No skin-grafting of a granulating Chopart gives the least chance of a useful stump. The scar ultimately becomes the lowest part of the foot in consequence of the contraction of the tendo Achillis, and will not bear the weight of the body without ulceration. Months of suppuration have often followed a guillotine amputation performed through the centre of the tarsus. A Syme is ultimutely necessary, and should be resorted to early.

Neither a sub-astragaloid amputation, nor a Pirogoff, gives the most useful foot. In both these amputations the lowest end of the leg is pointed and irregular, the stump is too long, and the artificial foot so narrow as to prevent the ankle-joint being fixed in the artificial foot itself.

A Syme's amputation is the best about the ankle-joint. It should be performed exactly as described by its originator, the malleoli and a layer of the tibia a quarter of an inch thick being removed. This gives room for a joint in the artificial foot itself instead of in the lateral steel supports.

Any amputation through the leg between the ankle-joint (Syme) and a point six inches below the top of the tibia must be looked on as likely to give an unsatisfactory stump, and one which is, therefore, a tentative amputation.

It is permissible in France to perform such an amputation, because it is always doubtful whether the flaps will or will not slough; but such a method gives an unsatisfactory stump which is thinly covered, badly nourished, liable to blueness, anæmia, ulceration, and sinus formation. It is only permissible as a temporary expedient.

The best amputation of the leg is one where the bone is cut four to five inches from the upper edge of the tibia ("seat of election"), where the lower end of the tibia is square, and where it is well covered with healthy movable skin. A patient with such an amputation can carry a considerable part of the weight of his body on the end of the tibia, the remainder being borne by the lateral surface of the tibia and fibula and partly along the surface of the thigh, i.e., the points of purchase of the socket which carries the artificial limb.

After this amputation, with a well-fitting artificial limb, a patient can walk, run, and dance in such a way as to render it absolutely impossible, even for an expert, to decide which leg is artificial.

In this amputation the fibula ought to be cut half an inch shorter than the tibia, otherwise it seems to increase in length and to project. Should, however, the end of the tibia not be well covered with movable skin the weight of the body cannot be borne on the end of the stump, and has to be carried on the lateral surface of the tibia and fibula, the sides of the thigh, and the tuber ischii.

It is imperative that in any amputation at the upper third of the leg the knee-joint should be kept straight, as flexion may render a further amputation necessary, either through the knee-joint, or just above it. If the knee-joint is allowed to become flexed the hamstrings and the posterior ligament contract and shorten, and all these structures, even the posterior ligament, may require division; and even then it may be impossible to straighten the leg, and amputation at or above the knee-joint may be necessary.

Even one inch of the tibia, if well covered on the under-surface, gives a more useful stump than an amputation through or above the knee-joint. Endeavours should always be made to divide the tibia in such a way, and at such a point, as to get a good covering for its cut under-surface. If this is not possible, or if the flaps slough, or if for any reason it is inevitable that there will be a scar over the end of the tibia, it is better to remove the tibia and the patella by some sort of incision similar to that for a Stephen Smith amputation.

In every Stephen Smith amputation the patella ought to be removed, for if left it retracts and forms a wobbling excrescence, which prevents the accurate fitting of a thigh bucket. It is quite easy by means of an accurately fitting leather bucket, fitted with lateral steels jointed opposite the tubercles on the condyles of the femur, to fit an artificial leg to an amputation through the knee-joint. An artificial leg so made and jointed does not cause the projection of the artificial knee beyond that of the normal knee when sitting down, and the gait of a patient wearing such an artificial leg is excellent.

A transcondylar amputation of the femur, if well covered, gives a very good stump, but the edges of the bones should be rounded off, and the periosteum should be pushed up and replaced over the edges of the divided bone. In any amputation above the condyles, up to a point higher than the middle of the femur, the artificial leg should be made with a lacing bucket of leather, not wood. This lacing leather bucket should be made of strong sole leather and should fit accurately to the thigh. The tuber ischii should rest upon its upper edge, so that the patient's weight is transferred to the ground through the tuber ischii and partly through the friction of the skin against the inside of the bucket. As the thigh shrinks the bucket can be tightened in the lacing, doing away with the necessity of having a new bucket fitted or of wearing sometimes as many as a dozen thigh socks.

At or above the middle of the femur every amputation case should be fitted with a pelvic band, which should be accurately moulded to the body before the steel is hardened. It should extend from just below the anterior superior spine on the affected side round the body below the iliac crests to the opposite anterior superior iliac spine. The hip-joint in this pelvic band should be at a point opposite the centre of the great trochanter and half an inch above it. Such a pelvic band prevents the wobbling of the thigh and considerably improves the patient's gait.

Amputations in the upper third of the thigh, where the bone is divided at any point between the small trochanter and two inches below it, give a stump well-nigh impossible to fit with an artificial limb. If more than two inches of bone below the small trochanter cannot be left, then the femur should be divided at the small trochanter or through the great trochanter.

It is easier to fit an artificial limb where the bone has been exarticulated at the hip-joint than it is where the bone has been divided through the great trochanter or at the small trochanter, so that if a long thigh stump cannot be made there need be no hesitation in removing the upper end of the femur, provided, of course, that the condition of the wound as to sepsis and of the patient will allow of this rather more severe proceeding.

SIDMOUTH HOSPITAL FOR DISABLED OFFICERS.—On May 31st the Countess Fortescue opened, at the Sidmouth Baths, a hospital for officers suffering from stiff joints caused by wounds. The treatment will consist of radiant heat, massage, whirlpool and aeration baths, and the use of mechanical appliances. Dr. William Gordon, of Exeter, delivered an address congratulating Sidmouth on taking up a work of real national importance. The use of combined physical methods as an organised system was, he said, due to French initiative, while the efforts of the Balneological Section of the Royal Society of Medicine had resulted in the establishment of centres in this country on the lines of the clinic at the Grand Palais in Paris. Dr. Gordon laid stress on the necessity for early treatment in cases of crippling, the fact having been proved beyond question that great advantage was gained in the massage and manipulation of disabled limbs by the preparatory use of heat.

NEURASTHENIA IN SOLDIERS OF THE HOME FORCES.

BY F. W. BURTON-FANNING, M.D. CANTAB., F.R.C.P. LOND.,
LIEUTENANT-COLONEL, R.A.M.C. (T.).

(Report to the Medical Research Committee.)

THIS communication is entirely based on experience gained at the 1st Eastern General Hospital, Cambridge, where I was serving prior to going overseas with my present unit. Its object is to draw attention to the predominance of neurasthenia as a cause of going sick amongst our newly recruited soldiers. I use the term in its widest sense to include disorders of the nervous system which are believed to have no organic basis. No experience that I had gained in civil practice was, to my mind, of more importance than the recognition of the fact that neurasthenia in some shape or form is by far the most common of the ailments for which the doctor is consulted by patients who are up and about and generally following their occupations. Sydenham[1] states that "hysteric disorders constitute one moiety of chronic distempers." Hospital training hardly prepares one for the numerical importance of neurasthenia, nor for the disguises it may assume. I do remember that one of my teachers, Dr. F. T. Roberts, in enumerating the diseases which should be thought of in making a diagnosis of the case before him, was fond of beginning, "Firstly, gentlemen, it may be nothing at all." Equally astonishing as the frequency with which neurasthenia underlies patients' maladies is the fact that in such a large proportion neither they nor their doctors are aware of the true explanation of the symptoms. But the majority of neurasthenics in civil life are keeping at work. I was not prepared, therefore, for the astounding prevalence of neurasthenia in the occupants of beds in a military hospital. The country is suffering an enormous loss of man-power on this account; there is also the great expense of these men's treatment in hospitals, their occupation of precious beds and attention, and there is the moral and physical deterioration of the patient to be thought of. Numbers of my patients have spent far more time in hospitals and convalescent homes than with their units. They are passed from one institution to another, they presently return to their battalions, where they immediately report sick again and are readmitted to hospital. Such a patient was asked: "How long have you been in the Army?" He replied: "Three weeks, sir." "How often have you been in parade?" "Every day, sir—sick parade," he explained. These are not exceptional instances, but they could be multiplied indefinitely and are of daily recurrence at any hospital which admits soldiers from the Home Forces. To a large extent I believe these losses could be prevented.

General Description.

During the last ten months I have had charge of a number of medical beds in the 1st Eastern General Hospital which had carried from time to time between 120 and 180. Into these beds 2240 patients have been admitted in the ten months, of whom 640 came in convoys from overseas and the remaining 1600 were from Home Forces. Out of this last number 509 were thought by me to be suffering from neurasthenia and to be free from any organic disease. It would appear, therefore, that, speaking from an experience of ten months in a Territorial Force Base Hospital, nearly one-third of the admissions into medical wards from Home Forces are for neurasthenia. A large proportion of them realised that they were of a nervous temperament and that this constituted their disability. A larger number were more or less ready to admit that they were nervous, but had not connected their supposed malady with this nervousness.

The remainder of the patients were unwilling to believe that their symptoms were not caused by disease of an organ, and they would not allow that their nerves had troubled them, although I was satisfied of the existence of evidence that they were of neurotic temperament and ailed nothing besides.

With a few exceptions, to whom reference will be made later, they were sure of their unfitness for military service and did not conceal their resentment at being called up. Many produced a treasured note, which certified that they suffered from some physical malady. All of them had the name of some disease ready on their tongues, which had presumably been endorsed by their doctors, civil or military. The doctor has apparently not borne in mind the extreme frequency of the neurotic factor in the production of symptoms and has not taken pains to discover the real source of the ailments. While allowance is made for the responsibility a doctor incurs when he brands a set of symptoms as neurotic, yet it is obvious that the neurasthenic will not begin to get well until he has been persuaded that he is free from any actual disease. This is the first point in treatment. While he is allowed to think that his sensations denote some particular bodily disease his thoughts are centred there and feelings are exaggerated. He is uneasy about his state of health and is persuaded of his unfitness for soldiering.

Though a number of these sufferers from neurasthenia are of average physical development and constitutional vigour, I have met with few whose physique or robustness was beyond the average. If the weight is occasionally excessive it is associated with flabbiness or want of tone. A large proportion are of notably poor physique. Stunted, weedy growth with small chest is common, and some are to be accounted degenerates. A natural lack of constitutional vigour affords excuse for drooping spirits and a sense of comparative unfitness. Supposing that sufficient force of character to disregard this infirmity is not exercised, a vicious circle is established and the physical condition is further lowered by mental disquietude.

This communication only deals with soldiers of the Home Forces, but I should like to allude to the fact that neurasthenia forms a part or the whole of the disability of an astonishing number of men invalided from overseas. A large proportion of those labelled shell shock, D.A.H., rheumatism, and other conditions plainly owe their ailment chiefly to a pre-existing neurotic temperament. Other minor maladies only assume sufficient importance to get the men sent to England, because they are mixed with the neurotic taint. But I have also seen a number of cases of wrecked nerves in men who had previously been above suspicion, and one can well believe that many conditions that have to be borne in the line are calculated to break the stoutest nerves.

Before passing to the enumeration of the symptoms complained of by my patients I would emphasise the point that the neurasthenic individual never confines his account to what might be explained by any one organic disease or by the affection of any one organ. The widespread distribution of his symptoms is the first point in diagnosis. If he makes rheumatic-like pains his chief complaint, he will go on to describe sensations in the head, in the heart, and the general manifestations of the neurotic state.

Bearing in mind the fact that of the patients by whom we are confronted a large proportion will be neurotic, the doctor should not commit himself to the diagnosis of organic disease, supposing there are no objective signs of this, and unless all symptoms present are thus satisfactorily explained. There is something to be said for the method supposed to have been used by an old R.A.M.C. officer. On a sick parade the odd numbers were allowed treatment and the even numbers were returned to duty.

The Story of the Neurasthenic Soldier.

My picture of the neurasthenic is very briefly as follows. In boyhood, perhaps, he began to evince the characteristics of the nervous temperament, and he did not readily accommodate himself to the rough and tumble of school life. Here I would say that although neurasthenia is met with in every social class, very few of my patients had enjoyed the traditional advantage of our old public schools. I am sure that faulty upbringing is to blame in a large proportion. Introspective habits have not been corrected, and they have not been told that their only rule is to play the man. The neurasthenic did not join in games, but he became serious and inclined to be contemplative. He is very often an only son, and parental upbringing has been injudicious. Later the trials of life are not met with philosophic buoyancy, and the mind is constantly occupied by disquieting thoughts. The nervous system becomes over-wrought and over-sensitive, and thus the working of the whole economy is deranged. While the controlling nervous centres are preoccupied and

[1] Allbutt: System of Medicine.

perturbed, it cannot be expected that subservient organs will do their work smoothly. Symptoms can mostly be explained by over-sensitiveness of the nervous system, exaggerated reaction to stimulus and the absence of well-ordered control over the internal organs.

To go on with the story of my neurasthenic soldiers, I have been told again and again that they "have always been obliged to study their healths." In their past lives they had been incapable of any but light or sedentary work. Many of them had felt themselves obliged to abandon one active occupation after another on account of their weakness. A very small proportion of my patients had enlisted voluntarily. Before the date of compulsory service we saw in this hospital nothing to compare with the recent outbreak of neurasthenia. They disagreed with the examining doctor's verdict of "Fit for service," and adduced previous rejections and their private doctor's opinion as to their delicacy.

They start soldiering, then, with the conviction that their strength will not enable them to stand it. They are suddenly thrust into an uncongenial atmosphere, they dislike the work, and find their comrades unsympathetic. It is not surprising that they should be upset at being torn away from their homes and their businesses.

Anything but heart and soul in their military vocation, they are not in the frame of mind to acquiesce in the roughness of the life and in the unwonted physical exercise. Few of them had previously taken hard exercise, so the first march with rifle and pack naturally caused some aching of limbs and other discomforts. Many of them blame their rations for having to go sick, some that they were always unable to endure cold and wet.

A fright put the finishing touch to a number of my patients. After perhaps some amount of questioning, several men confessed that they were afraid of horses. One promising recruit altogether collapsed on hearing his rifle go off. With a few there was at the bottom of their complaints a grievance, such as being ordered to perform menial tasks, or, in the case of officers, failing to get on with their superiors.

But I should like to mention here the fact that my neurasthenics from the ranks have hardly ever complained of inconsiderate treatment from their officers, commissioned or non-commissioned. Whatever finally determined their nervous breakdown, I almost invariably ascertained that they had suffered in a similar manner for years previously.

Symptoms and Signs.

As I have already said, the neurasthenic's symptoms are never limited to one region or to one organ, and there are certain almost universal general symptoms. Weakness, prostration, a feeling of exhaustion, or sudden collapse are invariable, and many of my patients have been sent in on this account alone as suffering from anæmia or some grave constitutional disease.

Want of energy and inability to interest or concentrate themselves are frequent causes of "going sick" amongst those engaged in office work. In contrast to the overseas sufferers from nervous breakdown, none of my patients made insomnia their chief complaint, though sleep was commonly stated to be broken and unrefreshing. As is so typical of the neurasthenic, the morning is always the worst time. These symptoms are all explained by the using up of nerve-force by mental preoccupation. Our minds must be at peace if we are to possess energy and *joie de vivre*. Other symptoms which are common to all neurasthenics, whatever may be their chief complaint, include tremors. These may be shown by the slightest quivering or over-action of the upper lip in speaking, by the rapid vibratory movement of the upper lids when the eyes are closed, or by fine tremors of the extended fingers. These phenomena are of importance because they put the examiner in the nervous track at sight. Violent tremblings and rhythmical contractions of the limbs or whole body are not infrequently seen and in many of my cases have been labelled malarial rigors. These are, of course, only the familiar manifestations of the nervous state of agitation, but patients have told me that when faced with a sudden emergency or call to action their quaking legs have refused to carry them.

Apart from symptoms referable to the heart there are a fairly constant group of vaso-motor phenomena—cold extremities, hot and cold flushes, which are usually described as the feeling of something creeping beneath the skin from the legs to the head, when they reach which giddiness or faintness may ensue. Sweating is a remarkably active function with neurasthenics. Moist palms or soles or steaming body often suggest the diagnosis, and it may amount to literal drenching of the whole body under circumstances of extra mental stress. I have never before seen such large beads of perspiration so covering the whole body as was constantly presented by a case of shell shock. I would here mention that in a neurasthenic patient whose symptoms had only become marked after being buried in the trenches the sweating was always limited to the left side of his face.

A large proportion of my neurasthenics manifested a marked sternal flush and less commonly a heated, suffused appearance of the face.

All my patients either complain of or admit loss of weight. This is of importance, because it seems to lend colour to the idea that they have some physical disease, but it really means nothing more than a wearing of the flesh off the bones from overwrought nerves.

This will be a convenient time to refer to a few signs that I commonly find present on examination. Exaggerated knee-jerks are generally recognised as characteristic of the neurasthenic and can be used to demonstrate to the patient the meaning of nervous over-sensitiveness.

Less generally recognised is a state of the tongue which I find of frequent occurrence. It has exactly the appearance of having been dried as by a cloth, and is thinly sanded or actually coated. Many patients have been treated, because of their tongues, for derangement of the liver or bowels or stomach, when in reality the condition is a nervous one. The old rice ordeal, in which the suspected person's guilt was established by his inability to swallow a mouthful of rice, depends on inhibition of salivary secretion in certain nervous states. These neurasthenics have many complaints to make about their mouths and their tastes. Sometimes the parched state of the tongue causes a characteristic habit in which moistening of the lips or attempts at swallowing are constantly taking place.

I examined most of my patients for the so-called stigmata of functional nervous disease—the concentric contraction of the fields of vision and anæsthesia of particular distribution. In more than half of my tested patients the fields of vision were normal and in those whose fields were contracted the other manifestations of the neurotic state were usually so marked that the test was only of use as confirmation.

Very few of my men were anæsthetic and the areas affected in them were variable—by no means always assuming the glove-and-stocking distribution. The occurrence of any anæsthesia, again, seemed to be confined to the more marked cases and did not help me in the detection of masked neurasthenia. Their pre-occupation of mind makes these people unreliable witnesses for delicate changes of sensation. Moreover, they are very susceptible to suggestion.

Patients' Chief Complaints.

In their order of frequency my patients' chief complaints or the diagnosis with which they arrived in hospital can be considered under the following headings.

Rheumatism.—This is the most common averred cause of disability. Pains in the legs, in the back, and less markedly in the arms are stated to be constant, but to be aggravated by marching. The joints are not necessarily the seat of the pain, and they are free from all swelling and deformity. There is no real limitation of mobility, but the joints are held stiff by obviously voluntary and exaggerated muscular resistance, the patient overdoing contortions of pain when they are passively bent. I should like to speak strongly about the number of these people who have been allowed their rheumatism, who have been ordered expensive treatment and have been sent for long courses of waters and massage and electricity to distant special hospitals. So soon, however, as the patient has been shown that the joints are perfectly free, and when he has been assured that there is nothing but a nervous condition present, it is easy to get these men straight out of bed and walking about the ward. A large number of these men have suffered in the same way before being called up, but in civil life they blamed cold or bad weather for what as soldiers they attribute to marching. A surprising number of these patients claim to have had rheumatic fever in the past. My attention was at once arrested by the frequency, as it would appear, of acute rheumatism in this class. A little scrutiny, however, satisfies me that their

statement cannot be accepted without question. It is elicited that the illness did not particularly affect the joints and that these were probably not swollen, but that the pains were universal, the chest, head, and body being painful. Most neurasthenics have some symptom referable to the heart, and in these people the supposed affection of the heart is connected with the alleged rheumatic fever. In a large number of cases labelled "Disorderly action of the heart" rheumatic fever is stated to have occurred in the past. In my opinion, however, closer scrutiny substantiates the neurotic rather than the rheumatic element.

As I have said, although such patients may claim to be completely incapacitated and are brought into the ward on a stretcher, it is usually particularly easy to get them on to their feet at once and finally dispel the pains.

The same kind of pains may have been called *neuritis*, but there is a complete absence of other symptoms or of signs of nerve inflammation. If such pain happens, for example, to be referred to the region of the sciatic nerve, this can be stretched without characteristically increasing the pain, and no wasting will be discovered. In my own experience careful measurements have helped me more than anything to discriminate between pain of organic and of functional origin. I have often been inclined to make light of a pain complained of in a limb, until my position was saved by the discovery of definite wasting.

Disquietude of mind is by far the most common cause of headache and of backache. A more critical survey of the local and general symptoms, the absence of signs of organic disease, and the manifestation of neurotic indications will usually make it easy to come to a correct conclusion in regard to these people. My point is that the doctor should have prominent in his mind the possibility of his patients' aches and pains being entirely neurotic. A conclusion will be arrived at by finding objective signs of organic disease conspicuously absent, by recognising that all the symptoms cannot be explained by any one organic disease, and that the individual presents manifestations of the nervous temperament. These patients are never easy in their minds, and their overwrought nerves become exaltedly sensitive. In ancient days it was recognised that another nervous state was capable of producing severe pains. Speaking of religious ecstasy, Father Poulain[2] says "the limbs may feel a great fatigue from it," and other ecstatics have "experienced severe pains" in the limbs, the heart, and the throat to such an extent that they were not expected to live. The same sensations are complained of by the neurasthenic soldier, and are equally due to psychic disturbance. A man was admitted to hospital bent down with backache and with painful legs. It was manifest that he was ill at ease, and he confided his grievance. Having originally been a sergeant, on rejoining he found himself a private, and this reduction was allowed to rankle in his mind. On hearing that he had been reinstated in his former position the pains at once vanished and his back became erect.

As a rule it transpires that the subjects of these painful limbs have long been of neurotic temperament, and the trial of a long march concentrates their attention on their limbs and increases their so-called rheumatism.

Gastritis is the term particularly affected by these patients and apparently by their doctors when the stomach is the seat of chief complaint. The name "gastritis" now suggests to me the inference of neurasthenia. I wonder what exact condition the doctor has in his mind when he diagnoses gastritis. Anyhow, the symptoms usually presented by these patients are pains about the stomach or perhaps elsewhere in the abdomen. These are brought on by food—especially by Army rations—and also by marching or by any upset. Tenderness is often exaggerated and mere pinching of the skin may give pain. The patient complains with much insistence of vomiting, which recurs in small quantities which are jealously preserved for the doctor's inspection. Dyspepsia does not present such a picture and the examination of the contents of the neurotic stomach gives no evidence of disease. Flatulence and pyrosis may be complained of and the tongue is furred. Constipation is the rule, but there may be nervous diarrhœa. A little investigation suggests that nervous disturbance is probably at the bottom of everything.

The Heart.

The heart, I should say, was the seat of some sensations in all neurasthenics, whatever may be the main complaint. Pain is complained of and is usually well below the heart, quite away from the common seat of anginal pain. It is generally a more or less continuous sense of discomfort, which is increased by exercise or by excitement. Palpitation, dyspnœa, giddiness, or actual faintings, together with the neurasthenic's general symptoms already described—are, in my opinion, also almost constantly present in all neurasthenics. These are the symptoms comprised by the condition termed "D.A.H." or "Soldier's Heart," which have been studied and described by the observers at the Hampstead Military Hospital.

The majority of my neurasthenics placed dyspnœa in a prominent place among their volunteered symptoms, and all but a very few answered a question about it in the affirmative. I am aware of the very important work that has been done[3] at the Hampstead Hospital on dyspnœa in some of their patients, and of the discovery of chemical changes in the blood. I can only state emphatically that most of my 500 neurasthenic soldiers presented this symptom. I think I can say the same of neurasthenics whom I have seen in civil practice. Certainly, also, my neurasthenic soldiers admit to having experienced all these symptoms of D.A.H. in different degrees before they enlisted. Time has not allowed me to keep more than rough notes and I cannot give detailed percentages. In my cases this would anyhow be difficult, because the same symptoms recurred almost constantly, it only being a matter of their differing in degree. I have observed the same general tendency to increased pulse-frequency in my neurasthenics as studied at the Hampstead Hospital and the same over-ready reaction to exercise and to excitement. Many of my patients appeared to maintain a rate of 100 or even more during all their waking hours, whatever means I took to secure their composure. During sleep, however, this frequency disappeared. I found the subjects of habitually rapid heart action particularly unamenable to treatment. Respirations were also generally quickened and preserved the usual ratio to pulse-frequency. I looked upon these conditions as being due to over-excitability of the cardiac and respiratory nervous centres.

The exclusion of any evidence of enlargement of the heart and the other negative conclusions arrived at by the workers at the Hampstead Hospital, after submitting their patients to examination by experts using every method of precise diagnosis, is most important. My own exclusion of organic affection of the heart was only based on ordinary clinical methods.

Amongst my civilian patients a common complaint has been a sense of inability to draw enough breath into the chest or to get it deep enough. This purely subjective difficulty has not been mentioned by many of my soldiers.

Nothing is more characteristic of the neurasthenic patient, especially where the heart is the seat of the prominent symptoms, than proneness to giddiness or actual fainting. I should say that the exciting cause is much more often emotion than exercise. From the description commonly given by the patient I imagine that the heart's action gets more and more tumultuous and rapid, until a kind of panic seizes him and he loses self-control and even consciousness. The brain cannot work with such a disturbed state of circulation; it is, so to speak, put out of its stride. I am absolutely in accord with Dr. Lewis in thinking that the word "heart" should not be used in the designation of these cases. The whole point is to reassure the patient as to the absolute soundness of this organ. I imagine there is some objection even to keeping them in a special hospital for diseases of the heart, though this objection is outweighed by the opportunity that has been given for the carrying out of the most valuable researches by the Hampstead Hospital staff. Personally, I soon abandoned the term "D.A.H.," and used instead the name "neurasthenia" for the whole class, without specifying from which organ the most prominent sensations arose.

I do not, however, agree with the proposed provisional term of "effort syndrome," because in my experience emotion is a more powerful cause than effort. Many of my soldiers could get no further with their drill than assembling on parade. A striking instance came before me recently in Norwich. A man who had been a gardener was called up

[2] Religion and Modern Psychology. J. Arthur Hill.

[3] Papers and reports by Dr. T. Lewis, Captain Cotton, J. Barcroft, T. R. Milroy, D. Dufton, T. R. Parsons, Major J. C. Meakins, Captains J. Parkinson and E. B. Gunson, Lieutenants J. G. Slade and A. E Drury, in British Medical Journal and Medical Research Committee Reports.

for service. He had been of highly nervous temperament since boyhood and dreaded being taken away from his village home. He fainted on his first parade and was in hospital in Edinburgh for some weeks. He rejoined his unit, fainted again, and was readmitted to hospital, this time for some months. At the end of this time he was invalided out of the Army with a good pension as permanently unfit from disease of the heart. During my examination his pulse-rate varied between 160 and 112 and his respirations between 40 and 28. The case was a distressingly marked one of general nervous perturbation, but it had this exceptional sequel. A few weeks later he wrote to me saying that he felt much better on being persuaded that his heart was sound, and, realising that an error had been made, he had renounced his pension and returned to work. I have now under my care a soldier whose cardiac and other neurotic sensations were tolerable until gas-helmet drill took place. Though there was no chemical in the helmet he felt overcome and fainted. On admission he was tremulous and overstrung, but the prominent symptoms were rapid heart action and respirations, which were increased by walking, but resumed their old ratio within two minutes after exercise. Nor do my observations bear out the theory of infection or toxæmia as the causes of these cardiac symptoms. I have already referred to my impressions as to the importance to be attached to the patient's statement that he has had rheumatic fever.

I grant that many patients are inclined to date their symptoms from some illness, and that of course many diseases do depress all functions, but in most cases evidence can be found of pre-existing nervousness. Further, an equal number of my patients have attributed their symptoms to an operation, which was required for some purely local trouble, such as hernia. An illness or an operation provides a more interesting reason for a breakdown than a fright or an injury to the feelings. And may not the illness which has been accounted the cause of the toxæmia have been in reality another manifestation of the neurasthenia? Undoubtedly the thermotaxic centre is as readily disturbed from nervous agitation as other parts of their mechanism. As regards other poisons, my notes bear out the conclusions of Dr. Lewis and his collaborators in regard to the much-blamed habit of cigarette smoking. Many of my patients who presented the described symptoms to a marked degree belonged to that serious-minded class of persons who eschew all forms of indulgence, except, perhaps, that of being doctored.

Alcohol is certainly productive of a particular type of nerve disturbance, in which remorse perhaps plays a part, but in these cases there is always the probability of some organic damage having occurred.

I have been on the look-out for any indications of thyroidism in these men, but in only two of the whole number was there any enlargement of the thyroid gland. In these two cases, apart from the common symptoms of excited action of the heart, tremors, and nervousness, there was more interference with nutrition and general health than in the typical neurasthenic. Their pulse-rate did not diminish during sleep in the same manner as did that of the neurasthenic. Moreover, though increased pulse-frequency is the rule in neurasthenia, I have notes of several cases with marked cardiac symptoms whose pulse-rates were slow under ordinary circumstances. Like my other cases, exercise produced an enhanced effect on pulse- and respiration-rate, which was recovered from in about three minutes.

Other Complaints.

Lung disease.—A considerable number of my men came labelled "Tuberculosis." Apparently the complaint of pain in the chest, of some difficulty of breathing, or of a streak or two of blood in the phlegm are thought sufficient grounds for mentioning this disease. Then such loss of a little weight and of strength, with a tendency to sweat, as are characteristic of neurasthenia become fastened on as corroborative evidence. Here we can take advantage of an outside verdict from the bacteriologist, instead of being obliged to ask the suspicious patient to take our word for his soundness.

The bladder is frequently the organ thought to be affected. Micturition is said to be frequent, or difficult, or unrestrainable. Backache is often associated with these symptoms. Nocturnal incontinence does not occur, and it is notorious that the complex act of micturition can be easily deranged by nervous states.

The throat is very commonly the seat of a variety of distressing symptoms in neurasthenia, but amongst my soldiers functional aphonia has been the only phenomenon met with as the prominent complaint associated with the throat.

The sexual organs have also been much less frequently involved with the soldiers' neurasthenia than with that of the civilian. With the soldier the organ which happens to be brought into use by his new work is the one that obtrudes itself on his sensations and begins to be surrounded by symptoms of suspected disease. In several of my patients the exacerbation of their neurasthenia could be traced to their consciences pricking them because they had contracted venereal disease.

Prevention.

I will touch very briefly on prevention and treatment, but I do want to call attention to my conviction that a great deal of neurasthenia must be laid to the door of the doctor who fails to make a strictly correct diagnosis and who does not disabuse the patient's mind of his apprehensions about the presence of organic disease. "The next best thing to a good physician is none at all" applies forcibly here. An officer was recently admitted under my care, whose chief complaint was of general weakness and sense of fatigue. He was also liable to giddiness and threatenings of faintness. All these symptoms were confidently stated to be due to weakness of the heart. I found no suggestion of disease about this organ, but a slight overaction of the upper lip in talking and a certain constraint of manner and of expression demonstrated nervous perturbation. Amongst other sources of worry he admitted being concerned about his heart. To my attempts at complete reassurance on this score he objected that nine doctors, including colonels, majors, and civilians, had told him that his heart was affected. As I was unable to convince him we agreed that he should consult a specialist, but, unfortunately, he did not help matters. He satisfied the patient that his heart was free from any suspicion of disease, but he gave him a certificate which stated that there was a particular tendency for the big vessels to become over-filled and drain blood from the brain. So the patient was left his physical infirmity to nurse. Whereas it is my opinion that if he had been assured that nothing ailed him except the effects of worry, he would soon have been relieved of all his symptoms.

In general the prevention of neurasthenia comes within the sphere of education. All social classes are affected, and I think my officers' ward has as large a proportion of neurasthenics as my other wards. But I do think that the class who furnish the greatest number are they whose education has been carried a little farther than that of their general station, but not yet far enough.

> "We knew too much, but not quite enough,
> And so we went to the wall."

The atmosphere of our public schools, in which character and manliness are developed side by side with learning, seems to prevent neurasthenia. A large number of my patients had followed sedentary occupations up to the time of joining, and even those who conscientiously wish to serve their country are over-taxed by being called upon to do strenuous exercise without any training. I am sure there would be fewer breakdowns amongst recruits if they could be better classified and gradually got on to full drill. It is everything with these men to establish self-confidence.

Treatment.—Prognosis.

Treatment seems to me to resolve itself into an attempt to remove from the mind whatever is the disturbing influence. The doctor's first task, therefore, is to gain the patient's confidence and discover the nature of his troubles. A careful physical examination should always be made, and in the large class where fear of some dreadful disease has been preying upon the mind reassurance on this point may be all that is required to give them a good start on the road to recovery. It is well worth the doctor's while to explain how mere loss of peace of mind can bring about each of their symptoms.

In many cases much patience is called for, and, of course, experience helps in the search for the cause. These people seem to go out of their way to delude themselves, and in good faith deny any worry when the existence of such is patent. I am reminded of a soldier who over and over again assured me that he was perfectly happy and easy in his

mind, and I could get no confirmation of my conviction that he was worrying. When it came, however, to his being discharged from the hospital he earnestly pleaded for some furlough. If he went home he could, he said, arrange a favourable sale of some land, which would otherwise mean a heavy loss to him.

Not only can the doctor, in all probability, show the patient that he has been taking the trouble unnecessarily much to heart and inculcate fortitude and equanimity, but he can do more. As Dr. W. H. R. Rivers pointed out to me, the mere unburdening of his soul confers relief on the patient. There may be more than we think in the act of confession.

On exhorting my neurasthenic soldiers to disregard their sensations and stick to their duties, I have often been answered by "I cannot do more than my strength allows." Broadly speaking, occupation is better for these people than rest. So with Colonel J. Griffiths's kind permission, these men were taken for daily and gradually increasing marches by a sergeant. Those who fell out were examined by me at once and it was easy to demonstrate to them their increasing abilities.

I will not attempt to answer the question, "What proportion of these men can be made into soldiers?" Not a few of my confirmed cases were made to see the error of their ways and returned to their units determined to do their bit. But in the case of the majority I cannot believe that real fighters will ever be made of them. The lifelong neurasthenic is not likely to endure cheerfully the privations and hardships of campaigning and will prove more of a nuisance than a help to his regiment. Nor can the neurasthenic be fired with the spirit required in attack and the willingness to make the supreme sacrifice. But there should be plenty of work at home or behind the line of which they are quite capable and which, after a little treatment perhaps, they should perform efficiently.

In conclusion, I must express my indebtedness to the sisters and nurses of my wards at the 1st Eastern General Hospital. Many observations and records were made entirely by them, and the burden of maintaining the right spirit amongst my neurasthenics and finding occupation for them fell entirely on their shoulders.

I have also to thank Dr. L. E. Shore, who had charge of the department for the diagnosis and treatment of nervous diseases and whose ready and skilful help was of the greatest assistance to me. He relieved me of what would otherwise have often been an uncomfortable responsibility when I ventured to exclude an organic disease supposed to be in existence.

NOTE ON

THE TREATMENT OF NEURITIS,

WITH SPECIAL REFERENCE TO SCIATICA.

BY HARRINGTON SAINSBURY, M.D.LOND., F.R.C.P. LOND.,

PHYSICIAN IN CHARGE OF WARDS AT THE BERMONDSEY MILITARY HOSPITAL, LADYWELL.

[THE treatment about to be recorded was recommended to me by Dr. HUGH WINGFIELD, of Welbeck-street. I have endeavoured to induce him to record his experience of its application, but since he has been unwilling to comply, and has suggested that I should undertake this, I have consented; it is, however, his treatment from beginning to end.]

At all times sciatica is apt to be an obstinate affection, so much so that, as one authority has put it, its treatment, or rather its resistance to treatment, has come to be regarded almost as an *opprobrium medicinæ*. It is for this reason that I am anxious to draw attention to Dr. Wingfield's treatment, which in its simplicity of procedure leaves nothing to be desired, and in its effectiveness has been so encouraging thus far that it is to be hoped others will be induced to give it a trial and thus test its efficacy. An additional reason for giving prominence to the method at the present moment will be found in the considerable prevalence of neuralgias and myalgias among our invalided soldiers.

The treatment consists in the direct application of the strong hydrochloric acid of the B.P., in common parlance fuming hydrochloric acid, to the skin, along the line of the inflamed and painful nerve. The acid in question contains 31·79 per cent. of gaseous hydrochloric acid and has a specific gravity of 1·160; in our text-books it is written down as an *escharotic*. That this acid should be capable of safe application to the bare skin will probably come as a great surprise to a good many who, like the writer, had been accustomed to treat it with great respect as a corrosive acid. The *modus operandi* is first to mark out the line of the nerve pain and tenderness as it happens to present itself in the individual. Sir William Gowers describes the areas of pain in sciatica as "usually most intense in certain spots—(1) above the hip-joint, near the posterior iliac spine, (2) at the sciatic notch, (3) about the middle of the thigh, (4) behind the knee, (5) below the head of the fibula, (6) behind the external malleolus, (7) on the back of the foot." These areas are to be selected when present. In general the practice of the writer has been to carry a broad line of application, some 1½ inches across, straight down the back of the thigh from the gluteal fold to the popliteal space; another application of like breadth for about 3 inches behind the head of the fibula along the oblique course of the external popliteal nerve at this spot; lastly, for some 5–6 inches behind the external malleolus directly downwards; and below the malleolus obliquely on to the dorsum of the foot. The extent of the tenderness will guide more or less as to the extent of the application. A wad of cotton-wool, firmly compressed into a knob of the size of the knuckle of the middle finger, is used to suck up the acid, of which about half a drachm to a drachm will be required. The charged wad, grasped by the finger and thumb (previously vaselined [1]), is then carried gently along the line of application above described. The degree of firmness may be increased subsequently if necessary, and the part may be painted two or three times at one sitting if the skin bears the acid well; the first application should be light and single in order to gauge the sensitiveness of the part, and if the integument happens to be thin and delicate it should receive correspondingly light treatment: Dr. Wingfield prefers to apply the acid with a camel-hair brush. A considerable smarting is sometimes complained of; in other cases little more than a tingling or sense of mild heat is felt. After the application a light covering may be thrown over the part till the skin is dry. The smarting soon passes off and the slight redness induced disappears also; no dressing is required. Rarely, in delicate skins, is a papular rash excited; it should be allowed to subside before re-application of the acid. Blistering has not been observed either by Dr. Wingfield or the writer. The treatment may be repeated twice a week if need be, perhaps oftener; it should be continued so long as the pain and tenderness continue. Massage may with advantage supplement the treatment, and particularly if there have been obvious wasting.

In three cases of sciatica recently admitted into the Bermondsey Military Hospital, Ladywell, the results have been striking and greatly appreciated by the patients themselves. Two of these were bad cases of long duration, and in one there was marked wasting of the muscles of the leg and thigh. Dr. Wingfield has had equally good results in sciatica and in the neuritis of other nerves also, and only once, in a case of neuritis of the upper arm, does he recall the occurrence of a troublesome rash, lasting about 14 days; this he attributed to a too free use of the acid. Amongst his cases he records a case of a neuritis of the arm accompanied by an acute eczema which prohibited the use of the acid; in this case he got rid of the eczema by the application of oleum Deelinæ, and having done this was able to apply the acid and cure the neuritis. These cases occurred for the most part in his past practice when physician at Winchester.

How does the acid act? It cannot be by virtue of its acidity—i.e., its power to neutralise alkalinity—for there is no alkali to neutralise on the surface of the skin, and the power of penetration of the integuments by this highly volatile acid, free to evaporate without let or hindrance, must be minimal indeed. Neither can it be due to its power to act as a counter-irritant, thereby deriving blood to the surface (*ubi stimulus ibi afflluxus*), and at the same time sending centripetally, for all they are worth, its sensory stimuli, the objections being that the afflux of blood observed is very slight and very transient (the development of a persistent congestion or mild inflammatory state is quite exceptional), and that the actual nerve irritation produced is

[1] This precaution is advisable if one should be applying the acid frequently, otherwise the skin of the finger and thumb tends to resent the repeated irritation

far below that which iodine and other established counter-irritants set up, with such disappointing results in respect of the cure of neuritis.

The explanation we must leave for the present, the point to arrive at now being the establishment, on a large experience, of the clinical value of the acid in the treatment of sciatica in particular and of neuritis in general, and, perhaps, of that nondescript class of complaint, now so prevalent and so troublesome, labelled "myalgia." Some cases of the last-named class—e.g., lumbago and allied painful conditions—have responded encouragingly; but at this stage it would be unwise to make too wide the terms of reference of this remedy: let the *fiat experimentum*, therefore, limit itself to sciatica and other forms of well-defined neuritis. The value of hydrochloric acid in these affections being confirmed, the investigation of the relative value of other members of the group of acids should follow naturally. The group is a large one, so large that perhaps it would be best to proceed next to the congeners of hydrochloric acid—viz., the other halogen compounds, hydrobromic and hydriodic acids. Though, according to the opinion of some, pharmacology be but an alluring madness, let there be "method in't."

Wimpole-street, W.

FREUD'S PSYCHOLOGY OF THE UNCONSCIOUS.[1]

BY W. H. R. RIVERS, M.D. LOND., F.R.C.P. LOND., F.R.S.,
TEMPORARY CAPTAIN, R.A.M.C.

THE usual course of scientific progress has been well exemplified, though perhaps in an exaggerated form, by the history of the theory of the unconscious put forward by Sigmund Freud, of Vienna. Few scientific theories escape the fate of being pushed by their advocates beyond the positions which they are fitted to hold, with the result that, failing to fulfil the expectations thus aroused, their merits are underestimated or they are even thrust into the limbo reserved for dead hypotheses, only to be rescued therefrom by some later generation. If we are to trust the contemporary medical literature of this country, this fate is now in store for Freud's theory of the unconscious. His views, or perhaps rather their applications, have stirred up such a hotbed of prejudice and misunderstanding that their undoubted merits are in serious danger of being obscured, or even wholly lost to view, in the conflict produced by the extravagance of Freud's adherents and the rancour of their opponents. This paper is an attempt to deal with the subject dispassionately from the point of view of one who has only temporarily been drawn by current events into the neighbourhood of the maelstrom of medical controversy.

Scope of Application of Freud's Theory.

The first point which may be noted is that Freud's theory of the unconscious is of far wider application than the perusal of recent medical literature would suggest. It is true that Freud is a physician and that he was led to his theory of the unconscious by the study of disease, but his theory is one which concerns a universal problem of psychology. If it is true it must be taken into account, not only by the physician, but by the teacher, the politician, the moralist, the sociologist,[2] and every other worker who is concerned with the study of human conduct. Not only does the medical controversialist fail to recognise that he is dealing only with one corner of the subject, but too often he looks on the whole matter entirely from the so-called practical standpoint and judges a theory of universal interest by the consequences which follow the application of the theory in the hands of the more extravagant of its adherents. It is possible, even probable, that the practical application of Freud's theory of the unconscious in the domain of medicine may come to be held as one of its least important aspects, and that it is in other branches of human activity that its importance will in future be greatest. I may perhaps mention here that my own belief in the value of Freud's theory of the unconscious as a guide to the better understanding of human conduct is not so much based on my clinical experience as on general observation of human behaviour, on evidence provided by the experience of my friends, and most of all on the observation of my own mental activity, waking and sleeping.

Unconscious Experience: Individual and Ancestral.

In the mixture of invective and witticism which may pass for a serious contribution to the subject in the medical literature of this country, an objection frequently put forward is that in postulating unconscious mental states Freud is putting together incompatible and contradictory ideas. One possible course is, that those who make this objection should see whether it is not possible to enlarge their conception of the mind, but to those who find this quite impossible a way out of the difficulty may be suggested. It would be an advantage if, instead of speaking of unconscious mental states, we were to speak of unconscious experience. Everyone would acknowledge that adult human beings have been the subjects of a vast body of experience of which they have no manifest memory, which does not enter into their manifest consciousness. Everyone would, I think, also be prepared to acknowledge that this body of unconscious experience influences our thoughts and actions, our feelings and sentiments. When we speak of such unconscious experience, we are keeping within the realm of obvious fact, although we are ignoring the problem concerned with the form in which the experience exists. Whether this unconscious experience is, or is not, to be included within the connotation of mind is largely verbal and depends on the definition of mind which we adopt. Since the science of psychology has until lately been almost exclusively concerned with problems of definition and description, it is natural that such a concept as that of Freud should meet with opposition, because it does not fit immediately into current systems of definition. The matter will perhaps become clearer if we consider the closely related body of experience which we term heredity. This term is only the name we have adopted for ancestral experience. When we discuss whether a given phenomenon, such as a morbid mental state, is due to heredity, what we really mean to discuss is how far the morbid state is the consequence of the experience of the ancestors of the patient. There have been those, such as Hering and Samuel Butler, who have extended the connotation of a psychological term so as to include this ancestral experience, and have regarded heredity as a species of memory. According to the more generally accepted usage this vast body of unconscious experience is not thought of as a whole in psychological terms. There are, however, certain elements in this ancestral experience which psychologists have singled out from the rest and have termed instincts, and they are agreed in holding that instincts form part of the subject-matter of psychology. If such unconscious elements derived from ancestral experience are by universal assent included within the scope of the mind, it is rather difficult to understand how it is possible to exclude unconscious experience acquired in the lifetime of the individual. It would be humorous if it were not pathetic, that many of those who object most strongly to Freud's views concerning the rôle of unconscious individual experience in the production of abnormal bodily and mental states should be loudest in the appreciation of the part taken by that ancestral experience for which they use the term, too often the shibboleth, heredity.

Mental Conflict.—Dissociation.—Sexual Experience.

Far more important than the largely verbal question whether the unconscious influences which mould our conduct are or are not to be regarded as constituents of the mind, is the question concerning what distinguishes Freud's theory of the unconscious from other theories which deal with this subject. A favourite statement concerning Freud's theory is that its fundamental idea is mental conflict. Standing out prominently in the system of Freud is the idea of conflict between the mental tendencies of the individual and the traditional code of conduct prescribed by the society to which the individual belongs. This conflict, however, was fully recognised by psychologists long before Freud. If this idea were the chief characteristic of his theory, no great claim for novelty or originality could be advanced. If a writer were to point to conflict as characteristic of human society, few would regard the proposition as either profound or especially illuminating, and the idea of mental conflict is in much the same case. The feature which makes Freud's theory noteworthy is his scheme of the nature of the

[1] A paper read at a meeting of the Edinburgh Pathological Club, March 7th, 1917.

[2] Cf. Sociological Review, 1916, ix., 11.

opponents in the conflict, and of the mechanism by which the conflict is conducted.

Another concept characteristic of Freud's psychology is that of dissociation, but here again the idea is older than Freud, and forms part of systems of psychology very different from his. The special merit of Freud's theory in this respect is that it provides a psychological theory of dissociation, of the factors upon which it depends, and of the processes by which its effects can be overcome. There is much to be said for a view which would regard as the distinctive feature of Freud's system his theory of forgetting. According to the views long current in psychology, forgetting is a passive process which stands in no special need of explanation. According to these older views, experience is remembered in so far as it is frequently repeated and according as it is interesting and arouses emotion, pleasant or unpleasant. It has been frequently recognised, however, that it is forgetting rather than remembering which needs explanation. It is, perhaps, the greatest merit of Freud's theory that it provides us with such an explanation. According to Freud, forgetting—and especially the forgetting of unpleasant experience—is not a passive but an active process, one in which such experience is thrust out of consciousness and kept under control by a mechanism, which by a metaphorical simile Freud has termed the censor. This censorship is supposed to act as a constant guard, only allowing the repressed experience to reach consciousness in sleep, hypnotism, and automatic or other states in which the normal control of the censor is removed or weakened. Even when the censor thus permits the repressed experience to become manifest, the experience is often only allowed to show itself in an indirect and often symbolic manner. It is this belief in a process of active repression of unpleasant experience which is the special characteristic of Freud's theory of the unconscious, and it is his doctrine of the part taken by such repressed experience in the production of bodily and mental disorder which is the leading feature of his theory in its relation to medicine. According to Freud many morbid mental states and many bodily states dependent on mental disturbance are due to a conflict between bodies of repressed experience, now usually called "complexes," and the general personality of the sufferer.

Still more important than nomenclature or theoretical basis as a cause of prejudice and misunderstanding has been the stress which Freud and his followers have laid upon sexual experience as the material of morbid complexes. In his theory Freud uses the term "sexual" with a far wider connotation than is customary, using it to comprise anything which is either directly or indirectly connected with the process of reproduction. His followers, however, and to a large extent Freud himself, have become so engrossed with the cruder side of sexual life that their works might often be taken for contributions to pornography rather than to medicine. In some of Freud's followers this absorption in the sexual has gone to such lengths that perverse tendencies and prurient ideas are scented in every thought, waking or sleeping, of the patients who come under their care. To a certain extent this excess is a reaction from the timidity and prudery of the great mass of the medical profession in relation to sexual matters, and is a kind of protest against the ignorance of this side of life which so often exists. The mistake which is now being made by many is to regard this excess as a necessary part of the Freudian scheme instead of an unfortunate excrescence, probably due in large measure to the social environment in which the theory had its origin. There are even those who are so obsessed by the sexual aspect of Freud's psychology that they regard sexuality as its basic principle and have fallen into a state of mind which wholly blinds them to its merits.

Evidence afforded by the War.

It is a wonderful turn of fate that just as Freud's theory of the unconscious and the method of psycho-analysis founded upon it should be so hotly discussed, there should have occurred events which have produced on an enormous scale just those conditions of paralysis and contracture, phobia and obsession, which the theory was especially designed to explain. Fate would seem to have presented us at the present time with an unexampled opportunity to test the truth of Freud's theory of the unconscious, in so far as it is concerned with the production of mental and functional nervous disorder. At least one redeeming feature of the ills which have resulted from the shocks and strains of the war would have been the opportunity they present of settling many problems concerning the nature and treatment of functional nervous disorders, and thus we might be helped in our endeavours to cope in the future with the similar states which follow the more ordinary strains of our modern civilisation. In my opinion this hope, so far as Freud's theory and the clinical methods founded upon it are concerned, is largely doomed to disappointment and I propose to consider briefly why this should be so. In my own experience, cases arising out of the war which illustrate the Freudian theory directly and obviously have been few and far between. Since the army at the present time would seem to be fairly representative of the whole male population of the country, this failure to discover to any great extent the cases with which the literature of the Freudian school abounds might well be regarded as significant. If my experience is a trustworthy sample, it would seem as if the problem was already well on the way towards settlement. Freud's psychology of the unconscious and the clinical methods founded upon it would seem to be proving themselves inadequate as a means of explaining and treating those disorders for which the theory was originally designed.

There are, however, certain features of the situation which must be taken into account before we should accept any such conclusion. First, it must be noted that, while the proportion of the population from which cases of war-strain are now being drawn is very large, it is not wholly representative, but has been selected, though in a very rough manner, by the medical examination preliminary to enlistment. There is some reason to think that many persons who would be likely to support the Freudian point of view, have for one reason or another escaped inclusion in the Army, or if they have joined are given work which does not expose them to the more severe shocks and strains of warfare. Another and more important reservation depends on the fact that warfare tends to produce states of anxiety and apprehension so deep-seated and far-reaching that they obscure causes of a different kind. Cases arising out of the war do not for this reason furnish satisfactory material whereby to test the truth of the Freudian position. Persons who break down under the strains of ordinary life in whom other states are not hidden by the overpowering emotional conditions arising out of modern warfare provide material which shows far more readily the influence of unconscious factors of the kind which are held to be so important by Freud and his school. Even when these reservations are taken into account, however, there remains singularly little to support the Freudian position in the form in which it is usually presented to us by its advocates. In my experience this is particularly true in regard to the part played by sexual experience in the production of the functional disorders arising out of the war. We now have abundant evidence that those forms of paralysis and contracture, phobia and obsession, which are regarded by Freud and his disciples as pre-eminently the result of repressed sexual tendencies occur freely in persons whose sexual life seems to be wholly normal and commonplace, who seem to have been singularly free from those sexual repressions which are so frequent in modern civilisation, especially among the more leisured classes of the community. It is, of course, obvious that the evidence in this direction, being negative, cannot be conclusive. The point is that while we have over and over again abundant evidence that pathological nervous and mental states are due, it would seem directly, to the shocks and strains of warfare, there is, in my experience, singularly little evidence to show that, even indirectly and as a subsidiary factor, any part has been been taken in the process of causation by conflicts arising out of the activity of repressed sexual complexes. Certainly, if results are any guide, the morbid states disappear without any such complexes having been brought to the surface, while in other cases the morbid states persist in spite of the discovery of definite complexes, sexual or otherwise, going back to times long before the war.

The denial of the validity of Freud's theory of the unconscious in the form currently held by its adherents, as the means of explaining nervous and mental disorders, is, however, something very different from the denial of the validity of this theory altogether. While in my experience instances of the kind which abound in the Freudian literature are rarely met with among the cases arising out of the war, there is hardly a case which this theory does not help us the

better to understand—not a day of clinical experience in which Freud's theory may not be of direct practical use in diagnosis and treatment. The terrifying dreams, the sudden gusts of depression or restlessness, the cases of altered personality amounting often to definite fugues, which are among the most characteristic results of the present war, receive by far their most natural explanation as the result of war experience, which by some pathological process, often assisted later by conscious activity on the part of the patient, has been either dissociated or is in process of undergoing changes which will lead sooner or later to this result. While the results of warfare provide little evidence in favour of the production of functional nervous disorders by the activity of repressed sexual complexes, I believe that they will be found to provide abundant evidence in favour of the validity of Freud's theory of forgetting, which in the earlier part of this paper I have regarded as the most striking and characteristic feature of his psychology.

Line of Treatment to be Adopted.

I do not attempt to deal generally with the practical consequences which must follow, if we accept the view that many of the symptoms which follow the shocks and strains of warfare depend on the repression of painful experience. I am content now to point out one consequence if we accept the position that certain symptoms of war-strain depend on the activity of repressed experiences arising directly out of the war. I believe that I am stating the orthodox view of the medical profession, I am certainly expressing that of the man in the street, if I say that the forgetting of unpleasant experience is held to be the obvious and natural line of procedure. The advice given takes such forms as: "Put it out of your mind," "Try not to think of it." Moreover, if the advice is not successful and the solitude of the night allows the painful thoughts to force themselves on the attention of the patient, hypnotic drugs, hypnoidal suggestion, or perhaps even definite hypnotism are employed to assist the process of driving the painful thoughts below the threshold of consciousness. When hypnotism or hypnoidal suggestion is employed, there is definite danger of producing directly just those states of dissociation which it should be our most vital duty to avoid, while it is a moot question whether the employment of hypnotic drugs does not tend to produce the same effect though in a different and more gradual way.

If the view I have put forward has any validity the proper line of conduct should be the direct opposite of that which is usually taken. Instead of advising repression and assisting it by drugs, suggestion, or hypnotism, we should lead the patient resolutely to face the situation provided by his painful experience. We should point out to him that such experience as that of which he has been the subject can never be thrust wholly out of his life, though it may be possible to put it out of sight and cover it up so that it may seem to have been forgotten. His experience should be talked over in all its bearings. Its good side should be emphasised, for it is characteristic of the painful experience of warfare that it usually has a good or even a noble side, which in his condition of misery the patient does not see at all, or greatly underestimates. By such conversation an emotional experience, which is perhaps tending to become dissociated, may be intellectualised and brought into harmony with the rest of the mental life, or in more technical language, integrated with the normal personality of the sufferer. As a matter of practical experience the relief afforded to a patient by the process of talking over his painful experience, and by the discussion how he can readjust his life to the new conditions, usually gives immediate relief and may be followed by great improvement or even rapid disappearance of his chief symptoms. It is in grave cases in which the painful experience of warfare has come to persons of somewhat neuropathic tendency, liable to the occurrence of dissociation, that this line of treatment is especially useful, but in slighter cases and more normal subjects there is much to be said for encouraging the patient to become familiar with his painful experience instead of treating it by the process of taboo, surrounding it, and assisting the tendency of the patient to surround it, with a halo of mystery. What is rather needed is the encouragement of that kind of familiarity which breeds indifference, if not contempt.

Value of Freud's Theory to Medicine.

I have only dealt superficially with some of the misunderstanding in which Freud's theory of the unconscious has been enveloped, especially in this country, while I considering the place which this theory seems de to take in relation to the vast mass of clinical expe which modern warfare is providing. I must conclu considering in the most general manner what I hold to b value of Freud's theory to medicine. Freud's theory of unconscious should appeal to the physician in that it provides him with a definite working scheme of influences, which he has long known to be active in the causation of mental disorders and of the bodily disorders which are traceable to mental factors. The modern conception of such disorders is that they are not merely the result of some shock or strain, but are the outcome of the whole life-history of those who suffer, that they are the result of the totality of the individual experience of the patient as well as of that ancestral experience which we call heredity. ' Of this ancestral experience and to a large extent of the individual experience, everyone will acknowledge that it is not accessible to the manifest consciousness of the patient and cannot be learnt from him by the ordinary methods of obtaining the history of the patient and his illness. The great merit of Freud is that he has provided us with a theory of the mechanism by which this experience, not readily and directly accessible to consciousness, produces its effects, while he and his followers have devised clinical methods by which these hidden factors in the causation of disease may be brought to light. For the physician who is not content to walk in the old ruts when in the presence of the greatest afflictions which can befall mankind, Freud has provided a working scheme of diagnosis and therapeutics to aid him in his attempts to discover the causes of mental disorder and to find means by which it may be remedied. My own standpoint is that Freud's psychology of the unconscious provides a consistent working hypothesis to aid us in our attempts to discover the rôle of unconscious experience in the production of disease. To me it is only such an hypothesis, designed like all hypotheses, to stimulate inquiry and help us in our practice while we are groping our way towards the truth concerning the nature of mental disorder. We can be confident that the scheme as it stands before us now is only the partial truth and will suffer many modifications with further research, but that it takes us some way in the direction of the truth seems to me certain. If this value of Freud's theory were only a probability, or even only a possibility, are we justified in ignoring it as an instrument for the better understanding of disorders of which at present we know so little? Are we to reject a helping hand with contumely because it sometimes leads us to discover unpleasant aspects of human nature and because it comes from Vienna?

SALVARSAN AND INTRAMINE, WITH REFLECTIONS UPON CHEMO-THERAPY.

BY J. E. R. McDONAGH, F.R.C.S. ENG.,
SURGEON, LONDON LOCK HOSPITAL, ETC.

IN my Hunterian lectures last year[1] I advanced the theory that the arsenic in salvarsan did not attack the parasites directly, but only indirectly by increasing the oxidising action of the protein particles in the serum and in the plasma cells. I also suggested that metals in general acted as oxidising agents, and that non-metals acted as reducing agents. As we had no powerful reducing drug analogous to salvarsan, I introduced a sulphur compound, and intramine, the name by which this sulphur compound goes, completed the chemo-therapeutic programme. I also showed to the best of my ability that the reason why chemo-therapeutic agents were more potent in protozoal diseases, and especially in syphilis, was due to the increased size and number of the protein particles, which circulate in the serum, forming the resisting substance of the host, or, as it is commonly called, the antibody. If it was proved that arsenic was not essential, it would be right to supplant it by another and less toxic metal.

In certain quarters what may be called the intensive arsenical treatment is now in vogue. Several injections up to 11 or more of the arsenical substitutes for salvarsan are prescribed and followed by an equal number of injections of mercury. The efficiency of such a treatment is judged by the negative

[1] THE LANCET, May 13th (p. 981) and 20th (p. 1025), 1916.

Wassermann reaction which is obtained at the end of it. As the Wassermann reaction is a purely physical reaction (surface-tension), depending upon the number and size of the protein particles in the serum; and as the administration of colloids, if continued long enough, sends many of these particles into solution, thereby making the reaction negative; and as the action of colloids is not a direct one on the parasites, it can readily be seen that a negative Wassermann reaction can give no indication as to whether any parasites are left behind or not. What light does clinical knowledge throw on the subject? Cases treated in this way may develop cerebro-spinal syphilis within two months of the cessation of treatment, and they are, to my own knowledge, gained in hospital and private practice, not few. Other cases may develop severe systemic syphilitic recurrences within the year. In both these classes of cases symptoms of the recurrence are present for some weeks before the Wassermann reaction becomes positive. In many of the cases which present no clinical manifestations the Wassermann reaction becomes positive within a year. Therefore the intensive arsenical treatment does not cure syphilis, and it may leave the patient in a worse condition than he was in at first.

I will now cite three cases out of the large number which have come under my eye, to illustrate what has just been said.

CASE 1.—In August, 1914, a patient had a single primary sore on the prepuce. He was treated with five intravenous injections of galyl, and with intramuscular injections of mercury for six months. In April, 1916, a pseudo-chancre appeared on the prepuce, close to where the original sore had been. The patient then had 11 intravenous injections of kharsivan, and 12 intramuscular injections of mercury. The sore just healed as the eleventh injection of kharsivan was given. In January, 1917, two pseudo-chancres appeared on the skin of the penis. I injected collosol iodine intravenously, and 5·0 c.c. of intramine intramuscularly, with the result that in a week's time the sores had completely healed and the induration accompanying them had disappeared.

CASE 2.—A patient came for treatment when the rash had only just entered the macular stage. He received nine intravenous injections of galyl, and three courses of mercurial injections. Before finishing the third course a large gumma appeared on the back and another on the abdomen. The Wassermann reaction was negative, as it usually is in such cases. Five more injections of galyl were prescribed, without any effect whatever; within ten days, after one injection of intramine, both gummata had completely healed, and the patient felt better than he had done for months.

CASE 3.—The patient, a man, aged 32, had a primary sore on the prepuce and had just entered the generalisation stage when treatment was commenced in June, 1916. The treatment consisted of 11 intravenous injections of kharsivan and seven intramuscular injections of mercury, which ended in August, 1916. Two months later the patient developed bad headaches and unsteadiness of gait. He soon became deaf in the left ear and had double vision. The pupils were unequal, the bilateral discs were choked, and there was paresis of the left auditory and oculo-motor nerves—due to basilar meningitis. The reflexes of the upper extremities were exaggerated; in the lower extremities they were unequal and diminished. Romberg's sign was present, the patient had pains down one leg, and had lost all sexual desire—due to a meningo-myelitis. An examination of the cerebro-spinal fluid revealed the following: Pressure raised; positive lymphocytosis, 650 cells per c.mm.; albumin and globulin increased; Wassermann reaction positive. From October, 1916, until the above examination was made, in January, 1917, the Wassermann reaction of the blood was negative (tested three times). Under colloidal iodine, colloidal mercury, and intramine injected intravenously and intraspinally (prepared serum) the patient recovered.

From the foregoing three cases, which are illustrative of many others, the following statements may be made. If the patient is in the primary stage and treated with oxidising agents only, should a recurrence appear it is most likely to simulate a chancre. If the patient has entered the generalisation stage then the recurrence, if systemic, will be a gumma, and if nervous it will be one of cerebro-spinal meningitis. These three cases show that the parasites are not attacked by the drugs directly; that the continued use of oxidising agents is injurious to the patient, as evidenced by the rapidity with which symptoms disappear when a reducing agent like intramine is prescribed; and that arsenic should be eliminated as far as possible from the treatment, as evidenced by the damage it exerts upon nerve and vascular tissue.

The processes of oxidation and reduction *in corpore* are regulated by iron and sulphur respectively, and as sulphur in the form of intramine has proved so successful, not only in hastening the disappearance of the syphilitic lesions, but also in reducing the number of the arsenical injections by half, I have attempted to prepare an iron compound analogous to it, which would supplant arsenic altogether, but up to now not with complete success.

Bearing in mind that the activity of a metal is largely dependent upon its atomic weight, and that mercury has been used for so many years in the treatment of syphilis, without producing worse toxic symptoms than stomatitis, gingivitis, and diarrhœa, it occurred to me that used in a colloidal state better therapeutic results would be obtained than were possible with arsenical compounds. It was a question as to whether the advantage given by the higher atomic weight of the mercury would more or less balance the advantage given by the amino groups in the arsenical compounds. Complex amino compounds of mercury are too toxic. Practical experience soon showed that the syphilitic symptoms disappear very much quicker under colloidal mercury than under salvarsan; roughly speaking, I should say that a full dose of colloidal mercury is more powerful than three full doses of salvarsan. The colloidal mercury, as it is now prepared at the Crookes' laboratories, is supplied as a 1 per cent. emulsion, ready for injecting. The dose is from 5·0 to 15·0 c.c., and the drug can be injected intravenously to out-patients without causing more than a little abdominal pain, diarrhœa, and tender gums, which usually disappear within 24 hours, or immediately after an intravenous injection of intramine. The tenderness of the gums begins to vanish while the patient is on the table.

When I first used colloidal mercury I employed too big doses and nearly had some fatal results, but fortunately the incidents proved instructive.

CASE 4.—The patient had a primary sore on the skin of the penis, general adenitis, and was more or less covered with a follicular syphilitic eruption. I injected intravenously 10·0 c.c. of a 5 per cent. emulsion of colloidal mercury. In the quantity injected there was 0·5 gramme of collo dal mercury, the action of which would be very much greater than 0·5 gramme of ordinary mercury. On the following day the patient had severe abdominal pain and diarrhœa. The diarrhœa increased, and blood was passed per rectum. This continued for a week, during which time not a drop of urine was passed. On the second day severe stomatitis set in, which became gangrenous a few days later. The patient also had hæmorrhagic conjunctivitis, herpes oris, looked and was desperately ill, and I had fears that he might die. This was a typical case of acute mercurial poisoning, and the mercury was acting as a poison in virtue of its oxidising power. This being the case, it struck me that the administration of an equally powerful reducing agent might cure the condition. I injected 100·0 c.c. of colloidal iodine intravenously, and 5·0 c.c. of intramine intramuscularly. Within 48 hours the diarrhœa ceased, and the patient passed nearly his full amount of urine. The condition improved so much from day to day that, with no other treatment whatever, he was perfectly well 18 days later, when there was no albumin in the urine and every syphilitic symptom had vanished.

Another patient received 10·0 c.c. of the same preparation intravenously the same day, having already had 10 0 c.c. injected intramuscularly three days previously. Therefore the patient had 1·0 gramme of colloidal mercury in his system. This patient had exactly the same symptoms as above described, and recovered in the same rapid way after an intravenous injection of colloidal iodine, and an intramuscular injection of intramine. I have had three other cases in which the symptoms were not so marked, smaller doses having been prescribed, which improved at once with one injection of intramine, In all these five cases the syphilitic manifestations disappeared in a few days, and some of the lesions were such as would not have vanished with six or more injections of salvarsan. The urine in these cases has been tested several times since, and has always been free from albumin.

Having obtained such accidental success with intramine in cases of mercurialism, I wondered whether the symptoms of arsenical intoxication would disappear as rapidly after its use. The following interesting case will show that intramine is also a specific for arsenical poisoning.

CASE 5.—A woman suffering from cerebro-spinal syphilis had six injections of galyl, three intraspinal injections, and then she took mercury internally for nine months. The last galyl injection produced an arsenical dermatitis which, in spite of treatment, persisted for nine months, when the cerebro-spinal symptoms reappeared. Within three days after an intravenous injection of colloidal iodine and an intramuscular injection of intramine the dermatitis had practically vanished.

These cases of metallic poisoning being remedied by a non-metallic drug like intramine, not only supports my theory of oxidation and reduction, but also explains why iodine should be useful in cases of plumbism. Doubtless intramine in cases of lead poisoning would be more valuable still. The reader will probably have noticed that whenever an injection of intramine has been prescribed it has been preceded by an injection of colloidal iodine. This is done because iodine is readily taken up by the mercaptan group, which is formed on the breaking down of the intramine molecule, thereby preventing the mercaptan group from exhibiting its affinity for oxygen, which, if allowed to do so, would diminish the effect of the intramine.

Realising the close similarity between arsenical dermatitis and other chronic eczematous skin eruptions, it struck me that the inflammation in some of the latter cases might be due to poisons having too powerful an oxidising or too powerful a reducing action. The following case will show the truth of such a contention.

CASE 6.—A woman consulted me for a chronic dermatitis of the arms and legs, which had persisted for five years and had yielded neither to ointments nor to X rays, &c. As the eruption was patchy and had persisted for so long, I thought the diagnosis of mycosis fungoides was possible. The patient also suffered from asthma, which I have noticed not infrequently accompanies chronic dermatitis, and as I believe this kind of asthma is due to an upset of the normal hydrogen ion concentration of the serum, hence affecting the oxidase-reducase system as well, I thought it possible that treatment along the lines indicated would prove successful. I gave large doses of strychnine, iron, and arsenic internally for three weeks, then an intravenous injection of colloidal iodine and an intramuscular injection of intramine, continuing the iodine treatment internally for three weeks more. The result was that the dermatitis vanished and the asthma disappeared also.

Being strongly of the opinion that intramine, colloidal mercury, and salvarsan, do not kill the parasites directly, but only increase the action of the oxidase-reducase system of the protein particles in the serum, it struck me that their combined use in any chronic infection would be useful. Naturally so good a result would not be expected in a chronic bacterial infection as could be obtained in syphilis, since in the former there are not so many protein colloidal particles in the serum, and it stands to reason that a direct ratio must exist between the beneficial therapeutic result obtainable and the number of particles present to be acted upon.

The following case of ulcus molle serpiginosum shows what a wonderful effect can be produced by the administration of powerful reducing agents.

CASE 7.—The patient had a soft sore in 1900. Five weeks after the sore had healed a bubo appeared in the right groin, burst, then healed up, to break down again a few weeks later and form ulcers, which spread up over the abdomen and down the right leg to below the knee-joint. The ulceration was still spreading in spite of various methods of treatment which had been employed, when the patient consulted me. Within 14 days after an intramuscular injection of intramine, 10·0 c.c., preceded by an intravenous injection of colloidal iodine 100 0 c.c., the ulceration, which had progressed without ceasing for 17 years, had completely healed.

I treated another case of ulcus molle serpiginosum, but with much smaller doses, as the patient was a nervous individual, and not nearly such a good result was obtained. I have since learned that, especially in chronic bacterial infections, such as gonorrhœal arthritis, &c., and in syphilis, the best results are to be obtained by using maximum doses of a few injections, and to allow as short a time as possible to intervene between the administration of any two of them. Satisfactory results cannot be obtained by commencing with small and continuing with gradually increasing doses. Before I found the correct dose of colloidal mercury I sometimes injected intramine intramuscularly on the same occasion as the mercury was injected intravenously, as the toxic symptoms caused by the latter were considerably diminished thereby. Theoretically, it was impossible to foretell whether the simultaneous administration of an oxidising and a reducing agent would be more efficacious or less so than allowing an interval to elapse between them. The following case will show that equally satisfactory results may be obtained by prescribing intramine and colloidal mercury together. This case had to be treated in the way prescribed as the patient would not have an intravenous injection, and it was imperative to rid him of his symptoms as quickly as possible.

CASE 8.—The patient had a hard sore on the right side of the glans penis and corona, an infiltrated papular rash, mucous papules in the mouth and between the toes, and very bad headaches. In this condition he had 10·0 c.c. of colloidal mercury (5 per cent.) injected into one buttock and 5·0 c.c. of intramine into the other buttock. The headaches passed away within 24 hours, the rash within eight days, and the sore with its induration had completely disappeared ten days later. The stomatitis, diarrhœa, &c., set up by the mercury was much less than the same dose had produced in other patients who had not had a simultaneous injection of intramine.

Owing to the pain caused by the intramuscular administration of colloids I have been attempting for some time past to prepare intramine suitable for intravenous use and have at last succeeded. The success has been largely due to the help given by my friend Mr. J. Ward, to whom I wish to express my thanks. Intravenous intramine is put up as a 0·1 per cent. emulsion, and the dose ranges from 20·0–100·0 c.c. Intramine injected intravenously causes no unpleasant sequelæ, with the exception of an attack of coughing just as the injection is finished.[2] Out-patients may be treated with it, and it does not cause venous thrombosis. The effect on the well-being of the patient by injecting intramine intravenously the day after colloidal mercury has been injected is astounding. While finding the correct dose for human beings, on two occasions I gave an overdose. Both patients received 20·0 c.c. of a 1 per cent. emulsion, with the result that they became very ill. They ran a high temperature, sweated profusely, complained of violent headaches, and had vomiting and diarrhœa. One of the patients had excruciating neuritis over the deltoid region of the right arm. Guided by the experience I had had with intramine curing mercurialism, on the third day, as the symptoms had not abated, I injected colloidal mercury intravenously, with the result that on the same day as the oxidising agent was injected the patients' condition became normal.

From this short article I think it is clear that the inclusion of arsenic in our chemo-therapeutic armamentarium is not necessary; that the combined use of oxidising and reducing agents is better than the employment of only oxidising or of only reducing agents; that the treatment of syphilis, so far as it affects the soldier's stay in hospital, can be very considerably diminished in duration; and that the severe after-effects, such as the increase in nervous syphilis, which will become more and more apparent, can be to a large extent avoided. Nine intravenous injections may be given in a fortnight, in which period practically any syphilitic symptom may be made to disappear.

This work also shows that, broadly speaking, our treatment of all diseases is the same, and that the therapeutic results are only more striking in protozoal diseases, especially in syphilis, owing to the peculiar physical properties of the colloidal protein particles in the serum of these diseases, which allow for a greater play of the processes of oxidation and reduction.

The treatment of diseases by drugs can never be perfect, since although the host attacks the poison or parasite by means of oxidation and reduction—a surface action—this oxidation and reduction is nevertheless regulated by the substratum to which the ions, which do the work on the surface, are attached. For treatment to be perfect we shall have to find out the chemico-physical nature of the various substrata, since specificity seems to depend upon the difference between them, and then to manufacture or synthesise them in the laboratory. At present drugs regulate the surface action, and vaccines, &c., the action of the substratum, but, unfortunately, the latter are not yet powerful enough to be curative.

ROYAL SOCIETY OF MEDICINE.

SECTION OF MEDICINE.

Tropical Diseases in the Balkanic Zone.

A MEETING of this section was held on June 12th, Sir RICKMAN GODLEE being in the chair.

Major ALDO CASTELLANI delivered a lecture on Tropical Diseases Found in the Balkanic Zone. That most frequently met with was malaria, the protean nature of which, though formerly well known, had been again brought into prominence. Pernicious cases were common in the late spring, summer, and autumn. The symptoms might simulate many other diseases and a wrong diagnosis might easily be made, with very serious results. Cases with symptoms pointing to lesions of the central nervous system were far from being rare, and he had met with the following types: (1) comatose, (2) delirious, (3) cerebro-spinal meningitic, (4) hemiplegic or monoplegic, (5) bulbar, (6) cerebellar, (7) tetanic, (8) eclamptic, (9) aphasic, (10) amaurotic, (11) spinal. The classical varieties of malaria, as described in the books, were not frequent. A purpuric and hæmorrhagic form had occurred resembling scurvy. It was marked by petechiæ and hæmatomata, spongy and bleeding gums,

[2] The fit of coughing may be avoided by neutralising the emulsion with sodium hydrate just before it is injected.

and sometimes bleeding from mucous membranes. The spleen, however, was enlarged, and although parasites were found in only about 10 per cent. of the cases, the cases reacted to treatment by quinine. Another blood condition which might be closely imitated was pernicious anæmia. The patient was generally a young man or woman with the typical pallor and lemon-yellow tint of pernicious anæmia; in some cases the liver was enlarged, or, more rarely, the spleen; there was either no fever or very little. The blood might be negative for malaria on repeated examination and show most of the common features of pernicious anæmia, including a high colour index. In elderly people the profound anæmia might give rise to the suspicion of internal cancer. The lecturer had come across cases of malaria simulating other specific infectious diseases. The typhoid type was far from rare; the patient looked like a case of typhoid and the temperature was typhoid-like, whilst the spleen was large but not hard. Bacteriological examinations for typhoid and paratyphoid infections, however, were negative, whilst the blood was full of malaria parasites which in this type of case were very little influenced by quinine. He had seen cases of pseudo-cholera and pseudo-dysentery of malarial origin and also of pseudo-tetanus due to the same cause. Several diseases of the digestive system might be simulated by malaria—e.g., appendicitis and cholecystitis. Malaria might affect the respiratory and circulatory systems. He had seen several cases of dry bronchitis of malarial origin and one case of pneumonia-like consolidation with bloody expectoration, and also 3 cases of typical angina pectoris all cured by the administration of quinine. Heart-block, of which he had seen one case, and tachycardia and cardiac arrhythmia might be malarial. He had met with cases of peripheral arteritis due to the same cause and also neuritic cases resembling beri-beri and others of local œdema.

As regards the diagnosis of the malady in the Balkans, he suggested the following rules: 1. Whatever the symptoms of the case, one should always keep in mind the possibility of malaria. 2. A negative blood examination is of no importance whatever unless the examination is repeated many times and at various intervals. 3. If quinine does not influence the fever, this does not always exclude malaria. 4. While giving very great importance to laboratory methods—for it is only by this means that a positive diagnosis can be made with certainty—do not neglect the clinical examination of patients. Train your senses as much as possible. The importance of simple inspection and of simple palpation can hardly be exaggerated. A slight abnormality of the colour and pigmentation of the skin, easily overlooked by the inexperienced, may suggest a diagnosis of probability in an obscure case, and acting on it may perhaps save the patient's life.

For treatment of the disease in the Balkans, quinine was by far the most important drug; it should always be given in very large doses, at least gr. 30 to 60 daily, by the mouth in ordinary cases, by intramuscular injection in severe cases, intravenously in the pernicious forms. It must be admitted, however, that there were cases which responded very slowly to a simple quinine treatment. In them other drugs had been tried, such as arsenical preparations, antimony, and picric acid. When given alone none of these had much effect, but when used as adjuvants to quinine, some of them (arsenic, for instance) seemed to increase its beneficial action. A treatment which had given him good results in certain cases was a combination of quinine, phosphorus, and tartar emetic. The prognosis was good in the enormous majority of cases if efficiently treated; but it must be remembered that in pernicious cases a high mortality might occur despite energetic treatment, and that in a large number of cases, even of the benign form, the cure was merely clinical, complete sterilisation not having been achieved. The affection lay dormant for months and years, and any cause lowering resistance, such as chill or traumatism, might cause the acute symptoms to reappear.

Next to malaria, the diarrhœas and dysenteries were the most common affections. The majority of cases of dysentery were of bacterial origin, but numerous cases of the amœbic type also occurred. Cases of enteritis due to flagellates and, much more rarely, to ciliates occurred. Coccidiosis had been observed. Cholera and paracholera had been rare. Attention should be called to the choleraic type of bacterial dysentery; also to a peculiar type of diarrhœa seen in Serbian soldiers who had suffered terribly from starvation during the Albanian retreat, which closely resembled the famine diarrhœa observed in India.

Camp jaundice was common. Two varieties might be distinguished: (1) a very severe type with high fever, lasting 10 to 12 days, and showing occasional relapses—true Weil's disease—which was rare; (2) a mild type, often afebrile and very common. Weil's disease was, of course, of spirochætic origin, but in his opinion it was probable that many cases of the mild type were also spirochætic. In addition to true camp jaundice there were also cases of jaundice due to malaria, due to paratyphoid, and due to streptococci; nor should the icteric type of relapsing fever be forgotten. Enteric fevers were fairly frequent in the Balkans, but recently had not taken any epidemic form. In certain districts paratyphoid A and B were more frequently met with than true typhoid. Similar fever due to various intra-intestinal germs were not rare. Cases had been found due to *B. colombensis*. Attention should be paid to the not rare association of mixed infections of the typhoid and paratyphoid organisms. He had seen two cases in which there was infection by all three. Malta fever was not common. He had only seen two cases in Macedonia, and the kala-azar of adults he had never seen in the Balkans, though he had met with many cases of the infantile type in certain islands of the Adriatic and Ægean seas. Relapsing fever was quite common. In its treatment he had obtained the best results by a combination of salvarsan, neosalvarsan, or galyl, with tartar emetic. Typhus exanthematicus was, at the present moment, very rare, although a terrible epidemic raged in 1914 and 1915. Trench fever was occasionally met with. Both of the types described in France had been recognised in the Balkans. Pappataci's fever was extremely common in certain parts of the Balkans, especially in the late summer and early part of the autumn. It was often erroneously diagnosed as dengue, though a few cases of the latter had probably occurred. A distinguishing feature of Pappataci's fever was the flushing of the face, which had often the appearance of being slightly bloated. This flushing sometimes amounted to an erythematous rash, which also involved the neck. It was very persistent and lasted long after the fever was over. The mucosa of the soft palate presented a peculiar appearance, numerous small hyperæmic roundish spots, sharply limited by a line of demarcation between the hard and soft palate, being visible, which also persisted after the temperature had dropped. Leucopenia served to distinguish it from incipient typhus. Broncho-mycosis and broncho-spirochætosis were observed. Pellagra was quite common in several districts of Macedonia, but he did not think there was any danger for our troops. Of the tropical diseases which were of rarer occurrence he mentioned filariasis, sprue, intestinal myiasis, mycotic, spirochætic, and flagellitic urethritis.

Certain tropical skin diseases were frequently met with. The following were a cause of great discomfort in summer, and were often wrongly diagnosed: Dermatitis interdigitalis, epidermophytis or "mango toe," tinea cruris or "dhobie itch," prickly heat, various types of tropical pyosis, such as pyosis Mansoni, pyosis discoides, &c. He had seen in 1915 in Macedonian peasants cases of ulcus tropicum, oriental sore, ulcus infantum, blastomycosis, sporotrichosis, accladiosis, &c., and also numerous cases of trichomycosis axillaris flava, nigra and rubra, of intertrigo saccharomycetica, and various other hyphomycetic affections. He had also observed two cases of Madura foot, two of keratoma plantare sulcatum, and one of ainhum.

ULSTER MEDICAL SOCIETY.—At a meeting of this society held on May 31st the following office-bearers were elected for session 1917-18:—President, Dr. W. D. Donnan; Vice-Presidents, Dr. R. Leathem and Dr. W. S. Smyth (Antrim); Council, Dr. A. G. Robb, Mr. P. T. Crymble, Mr. R. J. Johnstone, Dr. F. Symth, Dr. G. A. Hicks, and Mr. H. A. J. S. Murphy; secretary, Mr. S. T. Irwin; treasurer, Dr. V. Fielden; librarian, Dr. W. L. Storey; editorial secretary, Dr. C. G. Lowry.

Dr. L. A. Tarassevitch's "Medical Bacteriology," which we reviewed in THE LANCET of June 2nd, is issued by the Publishing House Collaborator (Russ. *Sotroudnik*), of Petrograd and Kieff, who are being asked to send some copies of the book to England.

Reviews and Notices of Books.

Le Traitement des Plaies Infectées. By A. CARREL and G. DEHELLY. Précis de Médecine et de Chirurgie de Guerre. With 78 figures and 4 plates. Paris: Masson et Cie. 1917. Pp. 180. Price 4 frs.

The Treatment of Infected Wounds. By A. CARREL and G. DEHELLY. Translation by HERBERT CHILD, Captain, R.A.M.C. (T.V.). With Introduction by Sir ANTHONY A. BOWLBY. London: Baillière, Tindall, and Cox. 1917. Pp. 238. Price 5*s.* net.

AT the present time the Carrel-Dakin method is in frequent use in our army for the treatment of wounds. Simplicity is its great merit, and the method has proved of extreme value in many cases, although the difficulty of keeping the patient dry is a not inconsiderable drawback. Exigencies of circumstances in a particular case or difficulty of travelling, moreover, may cause imperfections in the technique with corresponding delay in the healing, while it is obvious that a vertical cup-shaped wound, with a fair-sized mouth and no leaking places at the bottom or sides, is likely to respond most quickly to the treatment. A large part of the book is taken up with information as to laboratory procedure, while at the same time it does not contain the amount of clinical information which might have been expected considering the important claims made on behalf of the treatment. The technique is, however, very fully described, and the pictures themselves give a good idea of the results that may be expected from this medical sterilisation of wounds. We recommend the book to all our readers.

Captain Child's translation, the early appearance of which shows commendable enterprise on the part of the publishers, is well done and makes Carrel's work accessible to the English reader. Sir Anthony Bowlby expresses in his introductory note the appreciation of British surgeons at the front of the value of Carrel's method. Whenever it has been thoroughly carried out it has, he states, accomplished all that has been claimed by its author and has benefited thousands of patients. He strikes a note of warning in regard to attempts to improve on Carrel's method, holding that modifications should not be introduced until the original method has had a proper trial. The translation will ensure the method a proper trial in this country.

Treatment of Joint and Muscle Injuries. By W. ROWLEY BRISTOW, F.R.C.S. London: Henry Frowde and Hodder and Stoughton. 1917. Pp. 148. Price 6*s.* net.

WITH the object of advocating his own method of treatment for muscular disability by means of graduated contraction of muscles, using for the purpose a faradic coil specially designed to give painless stimulation, the author gives a general account of the treatment of fractures, as well as of joint and muscle injuries. He contends that the essential factor in these conditions is the treatment of the muscles themselves, whether affected by direct injury or by reflex atrophy; that restoration of function is more speedily obtained by his method of electrical stimulation than by the more usual treatment with massage, which he describes as very tedious and very slow in producing a good result; and active exercises against graduated resistance, which are of little service when atrophy is well marked. War surgery has given an impetus to the electrical treatment of peripheral injuries, and the author's method appears to be an attempt to use rationally means hitherto employed casually and without conviction as to any resulting good. An important chapter is devoted to the treatment of peripheral nerve injuries.

JOURNALS.

The American Review of Tuberculosis. Vol. I., No. 1. March, 1917. Published monthly at 2419–21, Greenmount-avenue, Baltimore, Md., by the National Association for the Study and Prevention of Tuberculosis. Price $2 per volume to members, $3 to non-members. Single copies 35 cents.—The aims of this new journal are explained in a brief preface by the managing editor, Dr. Allen K. Krause (Baltimore), to be: to offer all who are interested in tuberculosis a medium in which to present their work and through which to develop their views; to stimulate productiveness and to interest those not directly concerned with tuberculosis but working in related fields. The editor-in-chief is Dr. Edward R. Baldwin, of Saranac Lake, who is assisted by an editorial staff of six—Lawrason Brown (Saranac Lake, N.Y.), H. R. M. Landis and Paul A. Lewis (Philadelphia, Pa.), M. J. Rosenau (Boston, Mass.), Henry Servall (Denver, Col.), and Borden S. Veeder (St. Louis, Mo.), while many well-known names occur in the list of associate editors. Of the first number, 50 pages are devoted to three original papers dealing respectively with classification, chronic non-tuberculous lung infection, and serological studies; 15 pages follow of abstracts from current medical literature. The last decade has seen a great revival of interest in America for research work in tuberculosis, witness the Phipps foundation at Philadelphia, the Trudeau foundation at Saranac Lake, and the Dows foundation at Johns Hopkins Hospital. The new journal is the result of this revival, and should be an important aid in focussing attention on research, whether clinical, pathological, or social, in the field of tuberculous disease. It is attractively bound and printed. We wish the venture every success.

Veterinary Review. Edited by O. CHARNOCK BRADLEY, M.D., D.Sc.Edin., M.R.C.V.S., Principal of the Royal (Dick) Veterinary College, Edinburgh. Published quarterly. London and Edinburgh: W. Green and Son, Limited. 10*s.* 6*d.* per annum.—This quarterly periodical is intended as a summary of current work of interest and value to the veterinarian, whether his sphere of life lies in the laboratory or the domain of the clinician, and in this issue the editor takes his readers over the best publications in medicine (human and veterinary) and agriculture in Great Britain, and also culls discriminatingly from those of America. Commencing with abstracts from anatomical and clinical sources, Dr. Bradley summarises the latest researches in surgery, pathology, toxicology, and therapeutics. Thirty pages are devoted to notes on books and general bibliography, and the ground covered is very large, showing how many spheres of work, other than those which are purely veterinary, can be turned to good account for the benefit of the suffering animal. Those who make a study of the comparative side of nature should see this quarterly periodical regularly.

Abstracts of Bacteriology. Under the editorial direction of the Society of American Bacteriologists. Editor: A. PARKER HITCHENS. Vol. I., No. 1. Cambridge University Press and Williams and Wilkins, Baltimore. February, 1917.—The Society of American Bacteriologists has already earned the gratitude of workers in bacteriology, especially as an applied science, by standardising various methods and materials. A year ago the society began to publish an official journal, and it has now decided to produce a bi-monthly number of Abstracts of Bacteriology, the first of which has just been issued. The two journals bear to one another a somewhat similar relation to that which exists between the *Annales de l'Institut Pasteur* and the *Bulletin*. The vast increase in the volume of original publications on bacteriological subjects, in which America has taken an almost preponderating share, has rendered works of this character not only useful but necessary. The abstracts in the present number are confined to American bacteriological literature, but even so they fill some 70 pages, and the list of journals, admittedly incomplete, with which it is proposed to deal in the future number over a thousand. Bacteriology has so many relations with medicine, agriculture, and industry that its literature appeals to a wide circle of readers who are not necessarily interested in it as a pure science. To such readers works like the present are especially useful; they furnish a guide to multitudinous publications, though all abstracts, however good, must be used with caution, and cannot be regarded with safety as doing more than indicate the kind of information which may be found in the original papers. Except that the present publication contains the Proceedings of the Society, it differs little in method and arrangement from other periodicals of like character published in various countries, though the arrangement of the papers concerned with human pathology is a little unusual, since they are grouped not according to the micro-organism concerned but according to the system—gastric, respiratory, or circulatory—in which the organism may happen to cause disease. The journal is produced with the luxury of paper, type, and margin which we associate with American scientific publications, and is assured of a hearty welcome.

THE LANCET.

LONDON: SATURDAY, JUNE 16, 1917.

The Readjustment of Civilian and Military Medical Needs.

THE position of medical officers forming the *à la suite* staffs of the Territorial general hospitals, a large proportion of whom have high professional position as consultants in various branches of medicine and surgery, appears to us to require consideration in the circumstances that have been brought about by the long duration of the war and by the enormous size of our present armies. It was very generally assumed under the original scheme by which the Territorial general hospitals were staffed that the medical officers would, at any rate in large proportion, remain in touch with civilian practice; but, as a matter of fact, many of these officers have now taken service abroad either under the Imperial obligation of their commissions or in obedience to the patriotic call for active assistance which they considered could best be answered by proceeding to one of the scenes of action. The loss of these *à la suite* medical officers to civil practice in their areas was not at first considered sufficiently closely as a matter that might become nationally serious, but we can now all see that it has become a very serious affair, and that as the needs of the War Office make ever-recurring drafts upon the medical personnel of the country, a point will soon be reached at which common prudence will demand a close consideration and, if necessary, a revision of the position.

The Central Medical War Committee, whose personnel has been strengthened by the addition of the names of Dr. H. J. CAMPBELL (Bradford), Dr. H. J. CARDALE (Cubitt Town), Lieut.-Col. J. MICHELL CLARKE (Bristol), Dr. T. W. H. GARSTANG (Altrincham), Dr. ARNOLD LYNDON (Hindhead), and Dr. H. J. STARLING (Norwich), has had under consideration the difficulties that the liability to sudden removal of medical men engaged in civilian practice may cause in localities where the existing civilian doctors are already hard pressed to meet their engagements, and as a result they feel that the situation is one that should be taken in hand. It must be remembered that at the present moment we are at the easiest period of the year for medical practice both of a private and of a State nature. The incidence of all ordinary diseases save certain epidemics is now distinctly lower than can be expected as winter approaches with the numerous and deadly conditions directly attributable to its more rigorous conditions. This is giving cause for thought among all who know how depleted already are the ranks of civil practices, and in many localities a feeling of apprehension has been created among those who are competent to look ahead and wise enough to know what to expect unless measures of security are taken beforehand. One very obvious point seems to have entirely escaped attention. It must be remembered that medical men also are liable to sickness and to the results of overwork, and if the demands on the civilian medical profession in this the healthiest season of the year are so large that efficient service can barely be maintained in any locality—and we are approaching perilously nigh to the danger-line—in harsher times the community must run the double risk, on the one hand of having a larger percentage of sick among them, and on the other of having a smaller medical service, a certain percentage of the doctors being themselves incapacitated.

To this double risk the population should not be submitted if it can be avoided, while it is enhanced still further by the sudden detachment from different areas of the recognised specialists for the district. The sooner those competent to deal with the situation are able to take it in hand the better it will be for all. It seems to us that the matter is one for conference and coöperation between the authorities at the War Office and the Central Medical War Committee, which represents alike the recruiting agency for the Royal Army Medical Corps and the machinery for the maintenance of the good health of the civilian population. The whole country, with regard to the medical service, as with regard to the other interests and amenities of life, is prepared to subordinate civilian to military interests, but where a certain amount of adjustment between military authorities and lay organisations can make the burden on the civilian population less hard to bear, while in no way imperilling the efficiency of the Army, such coöperation is greatly to be desired.

Arrested Tuberculosis and After-care Factories.

THE need is generally recognised for the continued care of all forms of tuberculosis which have been the subject of institutional treatment, but little has yet been put into practical effect. It would be a public misfortune if the scheme which was inaugurated by the late Dr. J. E. SQUIRE for the after-care treatment of sanatorium patients should be allowed to lapse for lack of his driving-power; but we cannot think that this will occur, so obvious is it that effort along the lines indicated would be amply repaid. Superintendents of sanatoriums have long recognised that the results of their work were seriously imperilled for want of proper supervision of their patients after leaving the sanatorium. Sanatorium treatment can do no more than build up health to the point of arrest of disease; it is not intended to maintain this condition—indeed, the amount of accommodation provided, in this country at any rate, forbids such prolonged attention. But patients who have benefited by their stay in the sanatorium return to their former occupation without any idea of the risks of relapse that are incurred; they work ordinary hours, many of them in the whirlpool of factory life. During their absence in the sanatorium domestic finances

have frequently become straitened, and the inducement to work strenuously in order to earn full wages is therefore very urgent. Small wonder, then, that many arrested cases quickly relapse, with the inevitable result, for recovery from tuberculosis seldom proffers itself twice to any man.

The superintendents of sanatoriums, fully aware that this industrial ordeal will sooner or later have to be faced by many of their patients, have attempted to prepare them for it by organising physical labour of various kinds; but valuable though such exercise may be, it inevitably lacks the stimulus of being remunerative, at least to the extent to which the skilled craftsman feels that he is entitled. In most cases, too, this improvised labour bears no relation to former occupations, and may, indeed, be detrimental to the resumption of such occupations, as, for instance, when the delicate touch of the typist or stenographer is dulled by handling pick and shovel for agricultural purposes. In a report published two years ago by the Medical Research Committee on the prevalence of pulmonary tuberculosis in the boot and shoe industry, the situation was carefully considered and an interesting recommendation made, the principle of which may well be applicable to other industries. We summarised[1] at the time the essential points of the suggested scheme, of which the following extract gives the gist:—

> Briefly, the scheme is to establish, in connexion with the ordinary form of sanatorium, a workplace for the manufacture of boots and shoes. Here consumptive operatives in an early stage of the disease and convalescing patients could carry on their trade under medical supervision for such hours as they are able, and earn wages in proportion. As health is re-established the working hours and earning capacity would be increased, until finally normal hours could be safely undertaken in many cases, and factory employment resumed. The conditions under which work would be done should preclude any possibility of the materials handled becoming sources of infection. It would be among the more important advantages offered by the plan for a factory sanatorium if as a result of his stay an operative could be taught how to carry on his handicraft under hygienic conditions. The influence upon his fellow men of his acquired habits after his return to the factory might be considerable. Many circumstances seem to point to the boot and shoe industry not only as one in which the evils of phthisis are conspicuous, but also as that for which the establishment of a sanatorium in which employment is provided is most easily practicable. The industry is not a scattered one, but is segregated in particular towns, and the nature of its technical processes raises no insuperable difficulties to their performance under sanatorium conditions.

The plan here advocated seems reasonable and practicable, and is one which should forthwith be carried out. But various administrative details come up for consideration. Would after-care factories be counted as sanatoriums with a right to claim grants? Would Approved Societies pay sickness benefit to inmates of a sanatorium earning wages for part-time work? The whole subject is one that points to the need of the general supervision of medical relations towards the State that would be supplied by a Ministry of Health; for a centralising body would be able to unite the authority of the Local Government Board over sanatoriums and that of the Home Office over factories, on the common ground of the after-care factory.

The present time is opportune for preparing a general scheme, inasmuch as at the end of the war there will exist a number of buildings well suited for conversion into after-care factories—namely, the extensive national factories now used for munitions of war. These factories consist of a large number of more or less isolated single storey workshops, connected together by convenient platform runways; while heating, lighting, and power are all laid on to each workshop. Canteens, ambulance-rooms, doctors' quarters are also in existence. The installation of the requisite machinery for the manufacture of boots and shoes, for printing purposes, or for the tailoring trade, when these workshops are no longer wanted for their present purpose, should not be an expensive matter. The Chairman of the Investigation Committee of the Medical Research Committee, to whose report we referred above, is at the moment the Minister of Munitions, and we trust that Dr. ADDISON will not hesitate to use the establishments which he has brought into existence to meet the necessity of war for the purpose of re-establishing the health of workers when they are no longer required for their original purpose.

[1] THE LANCET, 1915, ii., 1359, 1422.

Hospital Sunday, 1917.

ON Sunday, June 24th, the Metropolitan Hospital Sunday Fund will appeal to the generosity of the public in London and throughout the United Kingdom, and again, as in many previous years, we press that appeal upon all, hoping that what we urge may find a hearing beyond the circle of our usual professional readers. The shadow of war which hangs over us does not lighten, but we face the struggle with a steady hope for a brighter future to come, prepared to meet with fresh economies the drain of war upon our resources. With the hospitals the case is different. Not on the future do they rest their hopes in consolation for present conditions of stress and uncertainty. Theirs is the present. The hospitals are doing their share, and more than their share, in meeting the present needs of the nation, of its soldiers and of its citizens, relying upon the nation's gratitude and the generosity of the benevolent to help them to meet the bill. The ground of appeal is a familiar one; we made it last year, and we make it again now. In no year since hospitals have existed in London has their claim been stronger upon the public gratitude, and in no year has their need been greater or more obvious to all.

In reminding the public of its debt to the hospitals, the sense of justice should stimulate its generosity and result in freely giving. Probably a large section of the population still forgets to name the hospitals of London among its creditors. Now and again some innovation—or supposed innovation—in medicine or surgery attracts popular attention in the newspapers, as in the case of certain antiseptics. To the man in the street it

appears, no doubt, that someone working in a hospital laboratory has been inspired by a brilliant or a happy idea, and that something of real utility in saving the lives or limbs of our soldiers at the front has been the fortunate result. What we want him to realise is that years, or it may be scores of years, of patient and laborious work in those hospitals, have led step by step, through good report and evil report, in all the discouraging circumstances of restricted opportunity and lack of funds, not to isolated "discoveries" and fitful progress here and there, but to results already rendered memorable in every civil and military hospital. Medicine has strained every nerve to meet the huge demands of war without neglecting the needs of a civilian population which runs the multitudinous risks of industrial life. The hospitals of the United Kingdom have trained the physicians and surgeons for their work and have placed their services at their country's disposal. In the laboratories and operating wards of the hospitals the whole scientific equipment of medicine and surgery has been developed and organised, and on them all future progress rests.

We claim for the hospitals of London no more than their just share of this great work; but the appeal of Hospital Sunday is primarily for them. The Metropolitan Hospital Sunday Fund is an opportunity for rich and poor alike. Its contributors include those who can afford to give large sums, and those other thousands who can give small sums. Their mites count for much, and the personal interest which those mites represent counts for incalculably more. Sunday is a visiting day at most hospitals, military and civil. Thousands of relatives in London will be sitting on Hospital Sunday at the bedside of men shattered by deadly engines of warfare, racked by war's diseases, overwhelmed by its shock and strain. We ask all of these to remember the hospitals for which the Metropolitan Hospital Sunday Fund makes its collection on that day. But besides these we ask all our fellow citizens to remember that in war, no less than in time of peace, the daily work of the hospital must be carried on in spite of high prices and financial strain for which time affords no parallel. The dangers and ills of civil life are still with us, and their contribution to the list of sick and wounded, always a large one, is liable to sudden variations. The street accident daily brings its quota of maimed and injured to the hospital wards, a constant stream liable to sudden increase by the destruction which the present week has brought. London remains the centre of a nation struggling for its existence against the foes without and the subtler foes within, against which its hospitals are the chief line of defence, and we call upon its citizens to realise their indebtedness and to make a generous response.

AN AMERICAN RED CROSS SCHEME.—A plan by which large industrial corporations will declare special dividends for the Red Cross has been devised in America. It is calculated to yield a minimum of £5 000,000.

Annotations.

"Ne quid nimis."

THE CROONIAN LECTURES.

IN his first Croonian lecture, on Adaptation and Disease, last Thursday, Lieut.-Colonel J. G. Adami, F.R.S., justified his choice of subject on the grounds that administrative duties had debarred him from sustained laboratory research and that the time was more than ripe for bringing the investigations of the bacteriologist and of the student of immunity to bear upon the important problems of general biology. The supreme biological problem of our times had been that of the ways and means of evolution; but while the fight centred essentially upon the cause or causes of variation: whether variability was, in fact, primarily inherent, proceeding from within, or primarily acquired, proceeding from without—this basal problem had been largely neglected for the secondary problem, whether properties acquired by the parent could be transmitted to, and reproduced in, the offspring. After briefly recalling the views of Lamarck, Darwin, Herbert Spencer, and Weismann, Colonel Adami dealt in more detail with Sir William Bateson's latest hypothesis that when a new property manifests itself in an individual of any species, it is not new, not due to addition, but to subtraction and loss of properties already possessed. According to this view, what appears to be a new property is primeval, the manifestation of a property possessed by the forerunners of the species, which all along has lain latent, present but unable to manifest itself hitherto in consequence of the co-existence of inhibitory factors. The sudden appearance of new determinants in the germ cell and the consequent accretion of new properties form no part of the Batesonian doctrine which, pushed to its logical conclusion, means that the primal unit, or units, of protoplasm from which all living animal and plant forms have descended, possessed within it in a latent form the originals of every organ and of every distinctive portion of an organ or part, even down to the conformation and colouration of individual hairs and scales. According to this view, what we regard as the higher forms of life were really the lower, owing their development not to progressive accretions of properties but to the reverse, so that reversion, instead of being a degenerative manifestation, a loss of properties acquired by the species, became a recovery of higher and completer powers. Colonel Adami queried whether any exercise of mediæval scholasticism ever led to a more perverse conclusion than this. Valuable and fascinating as were the recent observations for the amplification of Mendel's law, that law only established the extent of variation possible *within the boundary of the species*. Employing Mendelian methods, we produce at most different strains of a species which by a cross fertilisation with other strains produced in turn individuals reverting to the usual type. Such interplay was not, however, capable of throwing light upon the progressive development of new species. Sir Ray Lankester saw in "direct adaptation," as adopted by Herbert Spencer, the fallacy of all Lamarckian doctrine. But the fact constantly impressed upon the student of immunity and the worker in pathogenic bacteriology was that "direct adaptation"—i.e., a specific modification in response

to specific alteration in environment—was one of the basal phenomena of living matter. Colonel Adami proposed, therefore, to consider in his later lectures (June 19th, 21st, and 26th, at 5 P.M.) the evidence of adaptation as it affected the pathogenic bacteria, passing on to adaptation affecting man and the higher animals, and concluding with the application of these data to our conceptions of disease and of evolutionary processes.

WAR AND INSANITY: LUNACY AND MENTAL DEFICIENCY IN 1915.

Two annual reports on lunatics and mental defectives have recently appeared. One of these, the Third Annual Report (for 1916) of the General Board of Control for Scotland, is largely of a statistical character, although sufficient is said to show the malign effect of the war in the curtailing of expenditure and the shortage of trained attendants in the asylums. The other is the Second Annual Report (for 1915) of the Board of Control for England and Wales, of which the first part, just issued, is general in character and deals with certain points of contact between the war and asylum practice. It emerges, for instance, from the English report that under present conditions it is impossible to form any judgment as to the influence of the war on the numbers of the certified insane. Of the whole population a certain proportion become insane in ordinary conditions, and of the 5,000,000 soldiers a proportion will similarly suffer. As the military age includes the most healthy and strong, a smaller proportion would be expected to become insane than in the general population, and it is noteworthy that there has been a decrease in the admissions to asylums. The number of notified insane persons in January, 1916, was over 3000 fewer than in January, 1915, contrasting with the average increase for ten years past of over 2000. The reduction does not appreciably affect any particular class, but the war has had several incidental effects on asylum practice. For instance, a number of large asylums have been converted into military hospitals, the superintendents becoming temporary officers of the Royal Army Medical Corps, while a large number of male attendants have joined the army, their places being taken in some asylums by female nurses. On the whole this has been found to answer well, but some asylums have declined to receive maniacal men on this account.

In English borough and county asylums the decrease in male admissions was nearly twice as great as in females. This has been due to two causes: first, to the absence of men at the war, and, secondly, to the very serious and important reduction of the staff of male attendants called up to service, with the result, already indicated, that certain male patients are not sent to asylums at all. Many soldiers who have become insane are treated in military hospitals at home or abroad and are not certified, thus escaping what would sometimes be an unjustifiable stigma, while non-certification makes possible their return to the Army. Although the reduction in the number of admissions is, therefore, on several grounds and to some extent fictitious, the increase of employment and the improved condition of the working classes may be reasonably inferred to have had their influence. The death-rate among the insane population remained unaltered for the year, the excess of male deaths being due chiefly to general paralysis. But asylum dysentery increased during the year and this should give rise to serious thought, as a similar increase has been previously noted. In 1914 there occurred in 97 English asylums 1324 cases of dysentery, in 1915 the number was increased by nearly 100 per cent. There is room here for strict investigation, and it is worth noting that the disease had shown its growing prevalence before war conditions could play any part in causation.

Turning to work of a constructive nature, attention is called in the English Report to the growing feeling which exists among all classes that a time has come when the feeble-minded should be protected and the welfare of society promoted by the establishment of reception houses and colonies where defectives can be detained and trained. The war, unfortunately, has hindered the full development of the scheme, but enough has been done to prove the utility of the measure. Returns are given in the English Report showing the frequency with which the feeble-minded girl becomes the mother of several illegitimate children who may inherit mental and moral weakness, and who at any rate are sure to be brought up in the worst of environment and social conditions. There is no need in these columns to give further examples of the terrible danger that is constituted by that class of persons who have improper appreciation of the rules on which social life must be conducted, nor to insist on the need for a clear recognition of the responsibility of the State for the troubles which these unfortunates unwittingly bring upon themselves and on the whole of society. The partial and spasmodic treatment of these cases by the Poor-law is characterised as a grave administrative extravagance, and all must regret the small progress that has been made, owing to the war, in applying the provisions of the Mental Deficiency Act. Some compensation is fortunately afforded by the real impulse which has lately been given to scientific research into mental disease and mental defect.

THE BATTALION MEDICAL OFFICER.

THE Army is fortunate in possessing hygienists of high standing, text-books in sanitary science of great lucidity, and sanitary orders which have been worked out in the light of practical experience for a period now of nearly three years. Army sanitation has, in fact, attained a high level, far higher than can be hoped for in many departments of our home sanitation where the enforcing power of military discipline is absent, and the whole nation must take carefully to heart in the peace times which are coming the lessons afforded by the war. And it must be remembered that even in the presence of military discipline it is the individual soldier who carries out the sanitary régime, and on him, in the end, the efficiency as a whole of any sanitary administration depends. It is here that the battalion medical officer can play his part, for he is brought into intimate personal contact with the men, and on him rests the onus of impressing the elements of sanitation on them in a form which they can understand. In another column Captain Hugh W. Bayly lays stress on this position enjoyed by the battalion medical officer, and suggests that as a matter of routine such officers should issue standing orders for the guidance of those under their sanitary charge. The battalion is the smallest unit in military life, and, like the family in civilian life, tends to have individual habits of thought and its own way of expressing

them; and it is probable, as Captain Bayly suggests, that the most efficient sanitation may be got out of the battalion by a medical officer who studies its particular conditions. For the battalion to which he was attached as medical officer Captain Bayly drew up a code of sanitary standing orders which he found successful in that case, and we commend his suggestions to the consideration of other battalion medical officers. In an appointment which is frequently of a temporary nature it is not very easy to take the keen personal interest in the work which alone ensures its efficiency, but the battalion medical officer may well remember that the saving of lives depends as much, if not more, on his insistence on the sanitary instruction of the private soldier as on the more dramatic work of rescue and first-aid to the wounded.

ROYAL MEDICAL BENEVOLENT FUND: AN EMERGENCY APPEAL.

IT is now nearly a year since an appeal was made by the office-bearers of the Royal Medical Benevolent Fund for liberal support to a special emergency fund to assist medical men in temporary difficulty in consequence of having joined the Army Medical Service. A ready response was given to this appeal, enabling the Fund to deal with a number of urgent cases where help was needed, and to render in some of them more substantial assistance by coöperating with other benevolent societies, such as the Officers' Families Fund and the Professional Classes War Relief Council, any possible overlapping of effort being thus avoided. As time goes on the need has, unfortunately, steadily become greater, and in a letter this week in our correspondence columns an appeal is made for a much larger sum than was obtained last year. This sum should be forthcoming, whether from within or without the profession. The demands made on the medical man at the present time are searching and imperious; he is recognised as being more essential than ever to the community, and it is only fair that his work should not be hampered by mental anxiety for his own financial position, or that of his family if he is killed or disabled. The medical profession may well be grateful to the officers of the Benevolent Fund for their discerning labours on its behalf.

AN ESKIMO DEFICIENCY DISEASE.

THE recently-recognised group of diseases attributed to deficiency in the diet of certain ingredients present only in small amount (vitamines) is very limited. Beri-beri and scurvy are the best-known examples. In the *Boston Medical and Surgical Journal* of May 3rd Dr. John M. Little has described a disease known to the Eskimos of Labrador and Baffin Land as "kallak," which he regards as of this nature. The diet of this primitive people is mainly animal, and consists of seals, caribou, birds, and fish. Where civilised food is not available they depend for carbohydrates mainly on berries and on the partly-digested stomach contents of animals killed. Their great feast after killing caribou is a thick soup made of its stomach contents and blood. The mosses, grasses, young shoots, and leaves eaten by these animals are possibly transformed by their hardier digestion into forms assimilable by man. It is to be expected that when stress of circumstances reduces this limited dietary deficiency disease would arise, and this is so. The frequency of scurvy among the Eskimos is well known, but they appear to be also liable to another deficiency disease. Ten years ago, before the term vitamine was coined, Dr. Little described "kallak" in the *Boston Medical and Surgical Journal* as an endemic disease commencing with an eruption of pustule-like lesions in crops on the hands, elbows, buttocks, and other parts, no organisms being found until secondary infection takes place. There is intense itching, the course is protracted, and recovery ultimately takes place. Discussing the etiology he said: "While it may occur at any time of year, if they have plenty of seal flesh to eat they don't have kallak. Most of the cases, as well as the worst cases and the epidemics, occur in the autumn, after they have been living almost exclusively on a fish diet, and especially after failure of the berry crops." The best treatment is the addition of seal meat and berries to the diet. Dr. Little now suggests that the disease is due to some fat-soluble vitamine present in the fat of seals and caribou. That the disease is not racial but is due to the mode of life of the Eskimos is shown by the case of a young Scotchman who was wrecked on a whaler in Baffin Land and lived the Eskimo life for a year. He gave Dr. Little a good description of kallak, and said that he had almost died from it.

TECHNICAL OPTICS.

WE understand that arrangements have recently been completed for an important development in national industry on the scientific side by the establishment of a new department of technical optics in connexion with the Imperial College of Science and Technology at South Kensington. The department in question forms part of a larger scheme adopted by the London County Council in August last for the provision of instruction in this most important subject (in which the Council promised to find certain moneys for the scheme, if the Government also contributed), including post-graduate and research work at the Imperial College, a trade school, and senior day and technical courses at the Northampton Institute, and junior technical courses at two junior technical institutions, one in North London and one in South London. Since August last the Government, including the new Department of Scientific and Industrial Research and the Imperial College, have decided financially to support the Council's scheme and all the necessary assents have been obtained. The amount of money immediately available is £4000 a year for working expenses and £5000 for equipment and more immediate necessities of the department. The new department is under the management of a Technical Optics Committee of which the Right Hon. Arthur H. D. Acland is chairman, and at present it consists of 13 members representing the Admiralty, the Army Council, the Ministry of Munitions, the Royal Society, the National Physical Laboratory, employers in the optical trades, glass manufacturers, and the Imperial College; while two further members have yet to be elected representative of glass-workers and metal-workers. The same committee appointed by the London County Council is also an advisory committee to the Council. Mr. Frederic J. Cheshire has been appointed head of the new department at the Imperial College for a period of five years, with the title Director of Technical Optics and Professor of Technical Optics at the Imperial College. Mr. Cheshire's long experience and great ability in optical matters are well known, and practically ensure a successful begin-

ning. He has been associated with optical instruments for many years at the Patent Office, and since the formation of the Ministry of Munitions has been Deputy Director-General of the Ministry and Technical Director of the Optical Department of the Ministry. He is the present President of the Optical Society. It is expected that, subject to the conclusion of certain arrangements with the Treasury, Mr. Cheshire will accept the directorship, and it is anticipated that the organisation of the Department will be rapidly completed, and that training will begin at an early date.

CHESTNUTS AND ACORNS IN WAR SERVICE.

THE manufacture of modern munitions has so far implied a certain demand on cereals which otherwise could be used for food. This is an unfortunate diversion, and it is gratifying to learn that, instead of using cereals, other materials not so far made fit for human food, as, for example, the common horse-chestnut, are to be employed. We may point out similar possibilities in regard to the acorn, vast quantities of which are wasted every year. The composition of these nuts has something in common, as will be seen from the following figures:—Horse-chestnut: water, 38·9 per cent.; protein, 4·8 per cent.; fat, 4·6 per cent.; carbohydrate, 50 per cent. Acorn: water, 6·3 per cent.; protein, 5·2 per cent.; fat, 4·3 per cent.; carbohydrate, 45 per cent. The most important constituent of both is the carbohydrate, in the form of starch, while the acorn should have further value on account of the substantial proportion of fat which it contains. Neither nut has as yet been used to any extent for human consumption, and it is possible that their utilisation in some way or other, whether for food purposes or not, may be one of the results of the relative food shortage. The first step has now been taken in the substitution of these nuts for cereals in the production of munition agents. Other abundant vegetable products may also be pressed into service. It is, of course, possible to convert wood, linen, cotton, and the like into sugar, but the process of conversion does not yet appear to have attained practical dimensions or to have reached an economic stage.

THE "INDEX-CATALOGUE."

BY a happy coincidence, along with the group of American surgeons who have come to Europe's aid has arrived the last volume completing the second series of the great index-catalogue of medical publications, issued by the Surgeon-General of the United States Army from the Medical Museum and Library. The value of this catalogue to medical science it would be hard to exaggerate. It is one of the principal agents in the standardisation of medical records, ensuring that published work shall not be overlooked by later authors. The orderly arrangement of the index is in itself a work of genius, and has formed a model for other medical libraries all over the world. The Surgeon-General's library contained on August 1st, 1916, when the preface to this volume was written, more than 224,000 volumes and 337,000 pamphlets. In the index-catalogue as far as published appear 346,000 author-titles and 305,000 book-titles, as well as over a million journal articles and 5000 portraits. Within the last five years have died both the men mainly responsible for the production of the catalogue—viz., the chief assistant librarian, Dr. Robert Fletcher, in his 90th year; and Dr. John S. Billings, the principal upbuilder of the Surgeon-General's library, and the creator of its index-catalogue, at the age of 75. The general plan of a combined index of authors and subjects, arranged in dictionary order in a single alphabet, and the system of subject rubrics with cross references, were devised by these two men and blocked out prior to the publication in 1880 of the first volume of the first series; and these principles have been adhered to ever since. Dr. Fletcher devised all the abbreviations of periodicals employed in the catalogue up to the time of his death, and a list of these abbreviations and of the medical periodicals of the world—forming, in fact, almost a reference library in itself—is contained in this volume of the index-catalogue. Here the convenience of the reader has counted more than rigid adherence to uniformity, and this principle is conspicuous throughout the work as a whole. A third series of the catalogue is now in preparation. The medical profession is under a deep debt of gratitude to the Surgeon-General of the United States Army for a treasure-house of information.

THE PHYSIOLOGY OF THE PRE- AND POST-CENTRAL AND PARIETAL CONVOLUTIONS.

THE exact function of the central and parietal gyri has long been a subject of dispute among physiologists and clinicians. According to one view the cortical zones for motion and for sensation, situated in the central convolutions, are one and the same, physiologically speaking: in the same cortical area where end the afferent neurons from a limb the movements of that limb are initiated. Opposed to this conception, which has been upheld by a number of distinguished investigators, is a theory of the sensomotorium which regards the motor and sensory centres as anatomically and physiologically separable, the former being localised in the precentral and the latter in the postcentral gyrus. Various facts appear to lend support to this second theory. The cytoarchitectonic arrangement of the cortical layers of the precentral gyrus is quite distinct from that of the postcentral, and though differences in structure may not correspond to differences in function the fact is undoubtedly suggestive. With lesions of the precentral there is marked degeneration of the cortico-spinal (pyramidal) tract; with lesions of the postcentral practically none. In a number of carefully observed clinical cases pure lesions of the precentral have been unaccompanied by sensory symptoms, or these, if present, have been transient, while lesions confined to the postcentral or parietal areas produce symptoms that are almost entirely of a sensory nature. Recent experimentation in anthropoid apes and in man also has definitely shown that with weak electrical stimuli individual movements can be elicited only from the precentral gyrus, whereas in the case of a conscious patient whose postcentral convolution was thus stimulated sensations were produced and referred to the opposite hand, but they could not be obtained from the precentral. Finally, experimental extirpation even of small areas of the precentral cortex is always followed by crossed paresis or paralysis, while with removal of large sections of the postcentral no paralysis, or only a transient one, results. Mention ought, perhaps, also to be made of a third view, associated with the name of the late Dr. Charlton Bastian, according to which the central

gyri are purely sensory, the motor centres being entirely subcortical or spinal. Dr. M. Minkowski, of the University of Zürich, has published in the *Correspondenz-blatt für Schweizer Aerzte*, of March 24th, a detailed record of experimental research which he has conducted with a view to elucidating the subject. He used apes for the purpose, examining them at intervals for a year or longer after the operation. His conclusions may be summarised as follows. Removal of the precentral gyrus results in an immediate complete crossed hemiplegia, gradually clearing up and leaving a permanent hemiparesis; contralateral hemihypæsthesia is only an initial symptom which soon disappears, with a slight defect of deep sensibility as the only persisting impairment. Extirpation of the postcentral gyrus causes no paresis even at the beginning, but only a loss of sensation on the whole of the opposite side of the body. This involves particularly tactile sensibility and localisation, in which improvement gradually takes place, though there remains a permanent defect in the hand; pain appreciation is but slightly affected and soon recovers; deep sensibility is much impaired and improves slowly and imperfectly. After removal of the postcentral and the parietal convolutions, including the supramarginal, no paresis follows; there is, however, a severe hemianæsthesia for all forms of sensation, more marked than with removal of the postcentral alone; restitution is very incomplete; after two years (in one animal) touch and localisation of touch were still quite lost, while the sense of pain was distinctly less imperfect and the localisation of painful stimuli was often correct. Deep sensibility remains badly defective. The author agrees with the view that the motor and sensory representation of the opposite side of the body extends over the precentral, postcentral, and parietal cortex, but this region constitutes no uniform sensomotorium; on the contrary, it is subdivided functionally in a fashion that follows, to some extent, architectonic differences. Deep sensibility appears to be represented over the whole of the area (ataxia occurs as a temporary symptom only with involvement of both the parietal and the postcentral cortex); cutaneous sensibility with the appreciation of local signs is mainly but not entirely post-central; touch is widely represented over the whole, perhaps even more widely in a diffuse way; pain is less impaired than any of the other forms of sensation, and therefore has probably, according to Dr. Minkowski, a specially wide and diffuse representation in the cortex.

THE METROPOLITAN WATER-SUPPLY.

WE deal with the three monthly reports on the metropolitan water-supply issued during the first quarter of the present year. It is interesting to consider the amount of rainfall in relation to the quality of both the raw and filtered waters. The opening months of the year were characterised by a drop in the mean rainfall. Thus in January the mean rainfall was 1·55 inches, being 0·68 of an inch below the average mean rainfall for that month during the previous 34 years. In February and March the figures were 1·12 (−0·95) and 2·15 (−0·03) respectively. With regard to the quality of the water in *January* chemical examination showed that the raw Thames and Lee waters deteriorated as judged by the permanganate, turbidity, and colour tests, and improved as regards the albuminoid nitrogen test. The raw New River water deteriorated in quality on all tests. The filtered waters improved in quality as judged by the albuminoid nitrogen test (excepting New River, Grand Junction, and Lambeth), permanganate, and colour tests (New River, Chelsea, and Lambeth excepted). There was no change in the Southwark and Vauxhall supply as regards colour test. Comparing these monthly results with the 1916 averages, the raw Thames and New River waters yielded results worse than the average as judged by the usual tests excepting that for albuminoid nitrogen. Lee river water was better except as regards turbidity. The filtered waters yielded worse than average results by chemical and colour tests, East London, Kempton Park, Grand Junction excepted. All three raw waters contained in January more bacteria than the average for 1916, while the filtered waters were satisfactory. Coming now to *February*, the results of chemical examination showed that all three raw waters improved in quality, as judged by the albuminoid nitrogen, permanganate, turbidity, and colour tests. The filtered waters also improved in the light of these tests, and compared with the 1916 averages the raw Thames and Lee waters yielded better results. New River water (raw) was also better than the average as judged by the albuminoid nitrogen and permanganate tests, but worse as regards turbidity test, while there was no change in regard to the quality of colour. The filtered waters yielded results worse than their respective averages, as judged by the albuminoid nitrogen test (New River, Lee, and Chelsea excepted), but better than the average (Lambeth and Southwark and Vauxhall excepted) as judged by the permanganate and colour tests. The raw Thames and New River waters contained more bacteria and the raw Lee water fewer than their respective averages for the year 1916, while the filtered waters showed a high standard of bacteriological purity. In *March*, with a practically normal rainfall, chemical examination showed that the raw Thames and Lee waters deteriorated in quality as judged by the albuminoid nitrogen, permanganate, turbidity, and colour tests, while the raw New River water improved, as judged by the albuminoid nitrogen and colour tests, but deteriorated as regards permanganate and turbidity tests. The filtered waters showed deterioration in quality in some instances, while compared with the 1916 averages the raw Lee and New River waters yielded more favourable chemical results, but they were worse as regards the turbidity test. The raw Thames water gave better results by the chemical tests, but was not so good on turbidity and colour tests. The filtered waters yielded results worse than their respective averages in many instances, but as regards colour all the treated waters showed an improvement. The raw river waters contained fewer bacteria than their respective averages for the year 1916, while the filtered waters gave not unsatisfactory results.

THE Cavendish lecture of the West London Medico-Chirurgical Society will be delivered at the West London Hospital on Friday, June 22nd, at 8.15 P.M., by Captain Andrew Macphail, C.A.M.C., professor of history of medicine at McGill University, Montreal, who has chosen as his subject, "A Day's Work." Representatives of the medical services of all the Overseas Forces will be present and past Cavendish lecturers and the presidents of London medical societies are specially invited. Invitation cards may be had on application to Dr. Reginald Morton, 66, Harley-street, W. 1.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

The War Cripple: Accommodation and Vocational Training.

A YEAR ago the total number of soldiers returned wounded to Canada and still under treatment was 1530; on Dec. 2nd, 1916, the number stood at 2634; and since the beginning of the present year the numbers have rapidly increased, reaching high-water mark—namely, 5677 on April 15th, in spite of hundreds discharged in the meantime. Nearly all the recent arrivals have been convalescents, no large number of bed cases having been returned so far. According to the recent report of the Military Hospitals Commission, Canadian invalids in England have been reduced in numbers from 20,256 on Oct. 20th, 1916, to 14,545 on March 30th, 1917, the distribution being as follows: In Canadian hospitals, 8926; in sanatoriums for consumptives, 92; in British hospitals, 5527. The duties of the Canadian Military Hospitals Commission are, in the main, two-fold, to provide hospital and other accommodation for the returned invalid soldier, and to supervise his vocational training. The actual treatment and provision of medical personnel in the hospitals remain in the hands of the Army Medical Corps.

In regard to severer injuries the Military Hospitals Commission arranged some time ago with several general hospitals in Canada for accommodation for 1600 "bed cases." Accommodation is being provided for 1200 others in buildings taken over or erected by the Commission itself. At St. John, N.B., the armouries have been converted and are now ready for 350 of these cases; at Kingston, Ontario, the Convocation Hall of Queen's University has been turned into a hospital and is now ready for use with 550 beds; at Winnipeg, Man., a new hospital has been erected in the old Agricultural College with 320 beds, to be divided between convalescent and active hospital cases; at Quebec and Montreal the Savard Park and Grey Nuns' Convalescent Hospitals may be used for convalescent bed cases later on. Both are ready without any alteration.

For consumptives 1250 beds are now available, and the accommodation is being largely increased. At Kentville, N.S., the Commission has added two pavilions for 64 soldiers, with the addition of a vocational building; at Kingston, Ont., the new buildings at the Sir Oliver Mowat Sanatorium have been completed for 175 patients; at Hamilton, Ont., three smaller pavilions and a vocational building are finished, and two large pavilions are nearly completed; at London, Ont., three new pavilions are already in use and an infirmary building is being added; in Manitoba two soldier pavilions are being added to the provincial sanatorium at Ninette; in Saskatchewan the Earl Grey School in Regina is being transformed into a sanatorium; an infirmary building is being added.

More room is being provided for convalescents. A convalescent hospital is being erected at Halifax, N.S., with three residential buildings for 300 men, to be finished by July 1st; two Presbyterian College buildings to accommodate 125 men have also been taken over. At Sydney, Cape Breton Island, a private house in fine grounds is in commission with accommodation for 100 men. At Montreal the former Loyola College has been taken over and 100 are there, with room for 250; St. George's Home, holding 50 men, is also occupied. At Whitby, Ont., the magnificent hospital for the insane of the Ontario Government has been leased providing accommodation for 1500 before the end of the present summer and a vocational building is under construction; at Guelph, Ont., another fine provincial building will shortly be ready with accommodation for 800 men and will be the great re-education centre of Ontario for the men who need training for new trades; the new Salvation Army building in North Toronto will be an orthopædic hospital for some 450 men needing artificial limbs, a special building to be erected in the large hospital grounds for the Toronto artificial limb factory; a home for 30 incurables has also been established in a former private residence in Toronto, the first of its kind for Canadian soldiers. There is also a training centre for masseurs at a mission-hall in Toronto. At Coburg the Ontario Military Hospital will have its capacity raised from 144 to 275 by the erection of new buildings reserved for curable cases of shell shock and other nerve troubles. By the acquisition of Pickering College, Newmarket, Ont., another hospital for the insane has been established for 150–200 returned soldiers. At Moosejaw, Sask., the Ross Park School has been secured, and with two auxiliary buildings in the grounds will take 400 men. In Saskatoon, Sask., the handsome building of the Y.M.C.A. has been taken over for 158 men. At Edmonton, Alta., the College is being taken over from the Methodist authorities, and will accommodate 300 men. Near Vancouver, B.C., two school buildings are being transformed for 450 men, 50 acres of land being available for farming and other purposes. Near Victoria, B.C., a charming beach hotel is already occupied, and the accommodation is being increased from 125 to 225. At Sydney, on Vancouver Island, the rest-haven is being increased from 160 to 200.

At the ports of arrival great improvements are being made for men immediately on their arrival from overseas. At Halifax, N.S., a clearing hospital with 450 beds is already in use, part being reserved for tuberculous patients; the provisions for attention and care there are excellent, as well as on the hospital trains. At Quebec, the clearing depôt, formerly the immigration building, is being remodelled, and will house 1000; special accommodation has been set apart for cases of tuberculosis and mental derangement.

Altogether between 500 and 600 workmen are now at work on the various buildings mentioned for reception, treatment, and training of the returned Canadian soldiers.

The bodies entrusted with the duty of watching over the interests of discharged soldiers are the Military Hospitals Commission, the Provincial Commissions, and the Board of Pension Commissioners. The problem of securing the proper return of discharged and disabled men to civilian life will be made less difficult if a knowledge of the duties of these bodies and of the measures by which disabled men are cared for becomes general. The medical profession in Canada is performing a work of public value by spreading a proper understanding of these matters, and convincing soldiers and civilians alike that it is the duty of disabled men to accept all that treatment and training can do for them.

Toronto, May 1st.

THE CONTROL OF VENEREAL DISEASES.

Treatment of Venereal Diseases in Belfast.

ON June 6th, at a meeting of the board of management of the Royal Victoria Hospital, Belfast, it was unanimously decided to form a special department for the treatment of venereal diseases, as suggested by the medical staff.

The American Journal of Syphilis.

The second number of this new journal has reached our hands. It is published quarterly by the C. V. Mosby Company, of St. Louis (801–807, Metropolitan Buildings, St. Louis, Mo. Yearly subscription $5, or $5.80 in foreign countries), and edited by Dr. LoydThompson, of Hot Springs, Ark., assisted by an associate editor and 15 departmental editors, among whom may be noted the names of H. Noguchi (New York), E. L. Opie (St. Louis), L. F. Barker (Baltimore), and Major C. F. Craig, of the United States Army. On the cover appears a quotation from Sir William Osler: "Know syphilis in all its manifestations and relations and all other things clinical will be added unto you." This number contains nearly 250 pages of text, mostly devoted to original articles, the first of which is a reprint of Dr. Noguchi's Harvey lecture on spirochætes, an exhaustive study of the natural history of all known varieties of this group, containing a bibliography of 283 publications. Dr. F. Proescher and Dr. H. A. Seil (Pittsburgh, Pa.) contribute a long paper on the action of vanadium with particular reference to syphilis, basing their conclusions on experimental work with animals. A supplementary clinical contribution by Dr. A. W. Stillians (Chicago, Ill.), who used sodium hexavanadate in doses of 0·03–0·06 gm. intramuscularly or intravenously in cases of primary and secondary syphilis at a dermatological clinic, contains the conclusion that the salts of vanadium have a specific effect on syphilis, clearing up the clinical manifestations and favourably affecting the Wassermann reaction. Other papers deal with serological reactions and clinical cases. The number ends with an abstract of current syphilis literature edited by Dr. W. H. Deaderick (Hot Springs, Ark.), including, however, only four extra-American out of a total of more than 50 articles. The character of this journal amply justifies its appearance, and its issue should be a useful adjuvant to the campaign against syphilis.

Correspondence.

"Audi alteram partem."

WAR EMERGENCY FUND OF THE ROYAL MEDICAL BENEVOLENT FUND.

To the Editor of THE LANCET.

SIR,—The time has come to make a further appeal for the War Emergency Fund. This fund was instituted last year to afford assistance to members of our profession who, in consequence of having joined the Army Medical Service, find themselves in temporary difficulties. Many medical men when called up had to leave on very short notice, without time to make adequate provision for the continuance and maintenance of their practices during their absence. As the result they have had to face a severe fall in income even when supplemented by Army pay, while many expenses, such as rent, insurance, taxes, family maintenance, and education, could not be reduced. Although in a year or two after their return it may be hoped those affected will recover their position, still in the interval that help is and will be necessary, and it is to meet these needs that the War Emergency Fund was established.

To be effective the grants must be made on a liberal scale, and the fund from which they are to be drawn must be a large one. The sum obtained last year was about £4000. This is quite inadequate, as at least £25,000 will be required, if even a small proportion of those requiring assistance is to be helped. From the wealthier members of the medical profession, it is hoped, substantial sums will be received, but everyone will feel it a duty which he owes to his less prosperous colleagues to give the most liberal donation he can afford.

At the same time the appeal is not, and ought not to be, restricted to the medical profession. The public, too, may be rightly called upon to bear its share, and to show by liberal contributions its appreciation of the special services so freely rendered by the medical profession to the country.

The War Emergency Fund is a special department of the Royal Medical Benevolent Fund. It is kept separate and distinct from the ordinary operations of the general fund and is under the management of a committee specially appointed for the purpose. Communications should be addressed to the Honorary Secretary, War Emergency Fund, 11, Chandos-street, Cavendish-square, W. 1, to whom cheques should be made payable.—We are, Sir, yours faithfully,

SAMUEL WEST, President.

THE ANTISEPTIC "FLAVINE" (ACRIFLAVINE).

To the Editor of THE LANCET.

SIR,—Under the above heading an official statement by the Medical Research Committee appeared in your journal last week. As the original publication concerning "Flavine" was made from this department and based on work by several members of the staff (Browning, Gulbransen, Kennaway, and Thornton [1]), the unfortunate impression might be created unintentionally in the minds of those reading the Medical Research Committee's statement that we had neglected to acknowledge its share in furthering this work. I would, therefore, add to what it has said that when after the outbreak of the war it seemed to us that further investigation on antiseptics was urgently required, the Medical Research Committee was approached with a view to securing its support for this department of the Middlesex Hospital on the subject, and we met with most cordial interest, the first material outcome being that the Committee provided the emoluments of one part-time worker. As a result of the combined facilities afforded by the Hospital and by the Medical Research Committee it was possible to resume work on the lines of that which had been done by myself along with Gilmour [2] in Professor Muir's department at Glasgow University some years ago and before this country enjoyed the benefit of the operations of a State Medical Research Committee; thus we were able here to develop the investigation with a view to a practical application in the treatment of infected wounds. The introduction of Brilliant Green as an antiseptic in the treatment of wounds by Leitch [3] appears to have been a valuable practical outcome of attention drawn to this substance by our earlier work, and we have also recommended "Flavine" ("Acriflavine") as a result of the continuation of this work, the original experimental part of which was carried out here with a sample which had been supplied to us under the auspices of the late Professor Ehrlich in 1912. The Department of Biochemistry and Pharmacology of the Medical Research Committee has been especially helpful by preparing the latter compound, and so affording a considerable quantity for clinical trial of what, up till recently, we believed to be the most valuable member of this group; in this way they supplemented our slender store of somewhat less suitable compounds of the same type (acridine dyes), although the latter, judging by the opinion of Colonel Pilcher, D.S.O. (see Browning, Gulbransen, Kennaway, and Thornton,[1] also James [4]) and the report by Dr. Ligat,[5] also proved valuable clinically. The assistance afforded by the Medical Research Committee, as well as by the Royal Society's Scientific Grants Committee, towards this work of the Bland-Sutton Institute was acknowledged in the only publication which we have made. It is, of course, almost unnecessary to say that neither the staff of the Institute nor the Hospital has been concerned in any way with the production and supply of "Flavine." The Medical Research Committee's Department of Biochemistry and Pharmacology has since then continued to give us valuable aid, especially by providing an experimental supply of "Proflavine" (the basic constituent of which had been examined by Browning and Gilmour [6]). We have had no opportunity of acknowledging the latter, as we have as yet made no publication on the investigation of its properties. However, the tribute to the Committee's aid paid by Sir John Bland-Sutton in his speech at a recent quarterly meeting of the Board of Governors of the Middlesex Hospital and widely published in the daily press prior to the appearance of the Medical Research Committee's official communication, would appear to have anticipated the latter in a generous and sympathetic correction of any erroneous impression which might have existed anywhere in the public mind.

I am, Sir, yours faithfully,

C. H. BROWNING.

Bland-Sutton Institute of Pathology, Middlesex Hospital, June 11th.

*** Since receiving Dr. Browning's letter the following communication has reached THE LANCET from the Medical Research Committee:—"By the courtesy of Dr. Browning the Committee have had an opportunity of seeing the foregoing statement. They would entirely confirm the accuracy of the account Dr. Browning gives. Their communication to the lay press last week was made to correct so far as possible the results of recent statements made in the lay press which were based upon misapprehension of the present situation in regard to the properties and the supply of Acriflavine, and must have been an equal source of embarrassment to all concerned. They would greatly regret that their communication should be read in any other sense."

THE LUMLEIAN LECTURES AND MEDICAL RESEARCH.

To the Editor of THE LANCET.

SIR,—The last course of Lumleian lectures [1] relates without comment the transition from the purely myogenic conception of the excitatory mechanism of the heart, entertained not long ago by the new cardiologists, to the neuro-myogenic now gaining favour. The lecturer duly erects the familiar back-pressure ninepins in the new cardiological bowling-alley, of which the neo-cardiologist appears to be capable of entertaining only one conception, and proceeds to knock them over with his modern aspect bowls of cardiac failure. He makes no more sufficient reference to the influence of the mechanical valvular factor in the circulation than did Sir James Mackenzie, the Oliver-Sharpey lecturer in 1911, although some remarks of the latter in his letter in THE LANCET of May 26th suggest that his horizon has been somewhat widened on this point since that not very distant date. Questions of blood weight, blood pressure, and the relative influence of the arterial

and auriculo-ventricular valvular apparatus are not considered by Dr. G. A. Sutherland, while the differing conditions of the right and left cardiac circulation are quite inadequately dealt with, and in so far as they are considered at all, their concern with any specially modern aspect of heart disease is not obvious. He criticises at length some conclusions of Professor A. R. Cushny on the action of digitalis (to which Sir James Mackenzie also seems to refer in his letter in THE LANCET of May 26th) which do not quite square with a current conception of the new cardiology—that, namely, which denies the direct tonic action of the drug on cardiac muscle; makes, it will be admitted, no very generous reference to the contributions of previous workers; and concludes somewhat interrogatively by expressing the hope that he may convey to the rising generation of new cardiologists the benevolent regard of the venerable Fane of Harvey.

As I have said, in all this there is nothing very striking, original, or generous, yet this course evinces a peculiar resurgent property for discussion, as though it were the stalking horse of a propaganda in an unsympathetic atmosphere. The protagonist of the Newer Thought himself, in your issue of May 26th, now trundles another ball down the resounding alley already mentioned, to demolish the last standing pin of previous aspects of heart disease, with some added generalisations upon the philosophy of reaction and progress, implying, of course, a monopoly in the search of truth for those whom he regards as progressive. It is not my intention to follow him over the whole course of his remarks, or to consider either the novelty or utility of the semeiological index to the fruitful research of the future, on which he dilates. One appears to have been engaged in this research more or less all one's lifetime, but from the distinction which Sir James Mackenzie draws between the microscopist and the clinician I gather that he thinks more attention should be paid to the living phenomena of disease than to their explanation by ultimate results in structural change. In this connexion an excellent lecture by Peter Mere Latham (*b.* 1789) may be read with advantage (Heart Disease, Lect. IV.). I shall restrict myself to the consideration of that aspect of the question with which Sir James Mackenzie associated my name in his letter—namely, the significance of murmurs—and hope, if my matter does not convince him and his school of thought, that my manner may be controlled by the spirit of the first and greatest of the aphorisms of the Father of Medicine, the immortal first clause of which forms the motto of the Royal College of Physicians.

Is not this persistent attack upon back-pressure conceptions based upon a misinterpretation of symptoms and a misapprehension of the views of the majority of physicians for at least a generation? For what is back-pressure? Is it not the result of the retention in some degree in the heart, of blood which should be more easily projected from it? When Dr. Charles Bolton in his recently related experiments[2] produced ascites by partially ligaturing the inferior vena cava in cats, did he not produce as an immediate result back-pressure in an acute degree? For what purpose does the staircase of venous valves exist except to enable the blood to climb against gravitation during the diastolic pause in propulsion in one section of circulation and to prevent systolic back-pressure in another section? That the *vis a tergo* failing renders the climb of the blood more difficult is surely not a new discovery. From a study of the quadruped as compared with the biped circulation I showed in 1878[3] how the horizontal required a more powerful left ventricle than the erect animal, to produce an easy transit of blood, and failure of left ventricular force does not act solely by the diminution of propulsive, but also by the lessening of absorptic power with delay or rise of pressure in the pulmonary circuit and the right heart.

A young man, otherwise healthy, eats a heavy supper, vomits, complains of pain in the chest, becomes pallid, and dies within an hour. On examination the utility, even of the pulmonary arterial valves, is vindicated by the proof of their having ruptured and caused rapid venous stagnation and death. Similarly the sudden rupture of any valve or its attachments disorganises a heart much more rapidly than when the valve defect is slowly established and with it a compensatory hypertrophy of muscle takes place.

Another man with a much stenosed pulmonary arterial orifice and shrunk, but hypertrophied, right ventricle lives to be a septuagenarian, notwithstanding a universal adhesion of the visceral and parietal layers of the pericardium, *because* he has a specially large patent foramen ovale and the valvular apparatus of the left heart is sound.

If one desires to see an incontestable picture of cardiac back-pressure in a less acute degree than that produced by valvular rupture or experimental ligation, let him examine the radiogram of a tightly stenosed, buttonhole, mitral valve with dilated and unemptied left auricle and loudly accentuated pulmonic second sound. This condition may prove suddenly fatal without any indication of auricular fibrillation or any evidence of ventricular failure other than the final and unexpected syncope which terminates life.

Physicians who did not live to see the dawn and day of the modern aspect of heart disease believed that in time, sometimes in one way, sometimes in another, the driving ventricle failed to cope with the cumulative effect of blood retention or back-pressure, the failure being either gradual with the usual retrograde evidences of the triumph of stagnation over motion, or sudden and without any such manifestation. Within the memory of at least a generation only ventricular failure has been regarded as the cause of such disaster. Is there any other or better elucidation of the situation now? The very hypertrophy attending all increased difficulty in evacuating the heart, which we know is greater in some forms of valvular defect than in others, teaches the same lesson, and the failure to cope with the difficulty may arise now in one way and again in another. It may be by the gradual waning of force in a once "compensated" but later hypotonic or degenerated myocardium, by the exhaustion of the heart by some intercurrent myocardial storm, and at times apparently by inhibitory arrest or by starvation of the coronary circulation. The tachycardial heart may result in dilatation of the left ventricle with the development of well-marked mitral reflux declared by an unmistakable bruit of bicuspid incompetency, or in the small and contracted ventricle which has outrun its blood-supply, as shown by accumulated stagnation in the pulmonic circuit and venous heart and by the small empty left chambers of the organ, as in death from asphyxia or hæmorrhage.

Since, however, the question of cardiac adequacy was first mooted in the medical press, chiefly in connexion with recruiting for war, that of valvular disease as affecting the war-worthiness of the heart in the soldier has been considerably simplified for the neo-cardiologist, although it probably will be still more so for him if the war lasts a little longer.

I have stated how the adequate consideration of the subject was not entered upon either by the Oliver-Sharpey lecturer of 1911 or the Lumleian lecturer of 1917. Experience has, however, driven the new cardiologists[4] to advise a preliminary exclusion of recruits showing evidence either of regurgitant aortic disease or of mitral stenosis. If Sir James Mackenzie is in agreement with this conclusion he has changed his ground since his previous declaration of the innocuousness of mere valvular lesion in the presence of adequate ventricular force. That he has had the courage of his opinion, I know, for I have myself advised the rejection of candidates with aortic disease, both for the Army and for life insurance, whom he has considered suitable for both purposes. THE LANCET has also (July 22nd, 1916) in a leading article dealt with the responsibility involved in allowing recruits with aortic regurgitant disease to serve, and in a letter in THE LANCET (August 5th, 1916) on the soldier's heart I gave demonstrable evidence of the importance of the aortic valve in maintaining the circulation of the blood. This looked rather like forcing an open door, but some of the paradoxes of the new cardiology have made almost any discussion in cardiac matters more or less relevant, and have led to the restatement of many points once regarded as securely accepted. Even now the findings of the Report mentioned require comment. "The question," it says, "is not one of diagnosis but of prognosis. A man with stationary aortic disease may be capable, and often is capable, of far greater and more prolonged strain than is a man who with severe symptoms of the kind described has no murmur." In other words, that we are justified in gambling with the stability of a radically injured heart because it is at the moment in less parlous state than a heart inadequate from some other cause, native or acquired. This is an utterance very characteristic of the school from which it issues, which is apparently still obsessed by the disproportionate value it attaches to the

[4] Report of Medical Research Committee, No. 8, p. 7 et seq.

muscular factor in the circulation. It is some evidence, however, of a return to the appreciation of the truth in older aspects of heart disease that the new cardiologists should have conceded so much, and, as is their manner, unobtrusively, changing ground with as little acknowledgment of having abandoned a previous position as is possible. In view of the action taken in this Report, the matter raised in Sir James Mackenzie's letter of May 26th, with which I am now concerned, may be regarded as so far simplified that consideration may be limited to those cases which the authorities in question still allow to enlist and serve—namely, those showing systolic bruits at the base or apex of the heart, for the discrimination of which, as organic or functional, they consider auscultation to be a fallacious method of investigation. With a certain obvious modification, due to the difference between the exigencies of the soldier's life in war and the civilian's in peace, the considerations involved apply to both classes.

The first point to determine is whether the systolic bruit manifested in a given case is exo- or endo-cardial and what its potentialities are for affecting the action of the heart. In my letter in THE LANCET of April 14th last I stated that "many systolic bruits, transient or exo-cardial in nature, which are usually easily diagnosed and have frequently been fully appreciated, are, of course, negligible." Sir James Mackenzie asks me three questions in consequence: First, where he may learn that negligible cardiac bruits may be distinguished from those that are not negligible; second, where I can point to a single instance in which with clearness and precision directions are given for making this distinction; and third, where the principles for assessing the value of murmurs are to be found.

It is evident from these questions that he has missed the point of the statement I have quoted, as an organic endocardial bruit is never transient, except in some cases of recent endocarditis or in the presence of some degree of actual cardiac failure, when it may disappear for a time to return in the heart that has regained power, if it ever does so. His question ought to have been how organic were to be distinguished from inorganic or functional endocardial murmurs, and both these from exocardial bruits or noises. This, I stated, had frequently been pointed out and done.

That essentially inorganic non-valvulitic bruits are met with which it is impossible to distinguish while they last from valvular lesions is within the knowledge of all who have had any considerable experience of these matters. But such only occur in the presence of quite evident cardiac failure and are always systolic and apical. They never occur in the recruit or in those in ordinary health, and they may, as I have said, disappear if there is recovery of cardiac power. The physiological tricuspid leak to which Sir James Mackenzie has referred never gives bruit unless the impediment in the dextrocardial circulation is pathological, as in pulmonary embarrassment by emphysema or other cause and in the atonic hearts of some young people. The only exceptions to the apical position and systolic time of the functional endocardial bruit are the rare cases in which a pulmonary valvular diastolic bruit is met with in the presence of a well-marked mitral lesion with raised pulmonic pressure, which is surely back-pressure, and in some cases of high arterial blood pressure with a forced gape in the sigmoid valves. The inconstancy of these murmurs alone reveals their inorganic character. Such cases have, of course, no bearing upon the selection of hearts for any active occupation. The *exocardial* bruit is also systolic in time, whether at the base or apex of the heart, except when it shows the double-shuffle of a pericarditis.

Exocardial bruits and the transient endocardial bruits met with in apparently healthy and usually young subjects I need scarcely say, and I think Sir James Mackenzie will agree with me, are easily diagnosed by altering the posture of the person who manifests them and by noting the effect upon them and their relation to respiration. As such they have surely been frequently appreciated and have presented little difficulty in diagnosis by that instrument, discredited by the Report to which I have referred—namely, the stethoscope.

In the case of the soldier I maintain that *no* organic valvular lesion is negligible, although there may be degrees in the gamble with life and efficiency, if one passes some mitral reflux and direct aortic cases. To do either I hold to be unjustifiable, while to pass cases of mitral stenotic or aortic reflux lesions occurring in any degree whatever should be characterised in stronger terms. Those who would even think of passing such cases are only likely to be found among the so-called neo-cardiologists, and a chastened experience appears to be in the course of enlightening even them, if we may judge by some of the findings of the Research Committee's Report.

With the civilian the case is not quite the same as with the soldier. For the purposes of life insurance there are few organic valvular lesions which should be passed except in some cases for short periods and then with the risk recognised. But, as we all know, the civilian who is not called upon for strenuous effort may occasionally carry an organic valvular lesion through a long and not inactive life. So far as my own experience goes, the aortic orifice is always sound in such cases and the lesion mitral and reflux. Rare cases, such as that of the malformed heart I referred to, which survived to old age, are quite exceptional and explicable by anatomical conditions, which only emphasise the importance of the valvular factor in heart disease, and the necessity for reckoning with it in prognosis. The value, moreover, of the careful study of the timbre or note of an organic valvular murmur in a given case in which a standard of its audibility and pitch has been established may provide a gauge of the power of the chamber or chambers of the heart producing it. This point was early impressed upon me, and I have referred to it in various papers and publications. It has also been noted by others.

I hope I have now shown that the bruits I characterised in my "oracular" utterance in THE LANCET of April 14th as negligible and as having frequently been appreciated were exocardial bruits and those functional endocardial bruits which disappear or are markedly modified on exertion or change of posture and which are at times abolished by deep respiration. Sir James Mackenzie evidently desired to learn the criteria for the full appreciation of organic endocardial or valvulitic bruits. That is another matter, but may approximately be done, as many writers have pointed out. Perhaps among recent authors the late Sir William Broadbent dealt with the point most fully, although it has not been overlooked by others. One of the best writers on the auscultation of the heart was Peter Mere Latham, whose work on heart disease, published by the New Sydenham Society, with an introductory memoir by that master of pure English, Sir Thomas Watson, will always be worthy of perusal. The appreciation of organic murmurs can, however, only be approximately attained by attention to such considerations as their site, the character of the pulse, the changes in one or more chambers of the heart, and the auscultatory evidence, or absence of evidence, of tension in the pulmonic circuit. With these interesting topics I am not at present concerned, although I have incidentally had to touch upon them in maintaining the importance of the valvular factor in heart disease against exponents of the new cardiology. I am, Sir, yours faithfully,

ALEXANDER MORISON.

Upper Berkeley-street, W., June 2nd, 1917.

AURICULAR FLUTTER DISCOVERED BY RADIOSCOPY.

To the Editor of THE LANCET.

SIR,—I anticipated that one or more of our English radiologists would have made some remarks *re* the annotation in THE LANCET of May 26th concerning auricular flutter as seen by the radioscopic screen. It is already well known that this phenomenon may be clearly recognised under the rays and the proportion 1 : 3 or 1 : 2 easily determined, and this is taught in continental text-books on radiology, and in particular in those written by our French confrères. In October, 1915, a young soldier was brought into the X ray room at the East Sussex Hospital, Hastings, who appeared very nervous of the rays. The heart showed an obvious right auricular flutter with a rhythm of 3 : 1, which disappeared after 15 minutes, and was quite obvious to those standing round. Although I examined him on several occasions afterwards I never caught it again. So far as I know, this is the first time that a neurotic or functional auricular tachycardia has been noticed. The ordinary form of heart-block in the aged and the disturbance of rhythm produced by extrasystoles are generally clearly seen on radioscopic examination.—I am, Sir, yours faithfully,

WALKER OVEREND, M.A., M.D. Oxon.,
Chief Assistant, X Ray Department, St. Bartholomew's Hospital, and Honorary Radiologist, East Sussex Hospital.

St. Leonards-on-Sea, June 6th, 1917.

The War.

THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue :—

Killed.

Major A. V. Honman, Australian A.M.C.

Previously reported Missing, believed Drowned, now reported Drowned.

Capt. G. C. B. Hawes, R.A.M.C. (see THE LANCET, April 21st, 1917, p. 629).

Lieut. J. Naylor, R.A.M.C. (see THE LANCET, May 12th, 1917, p. 739).

Wounded.

Capt. S. S. Greaves, R.A.M.C.
Capt. B. C. Tennent, R.A.M.C.
Capt. F. P. Fisher, R.A.M.C., attached K.R.R.C.
Capt. A. G. M. Middleton, R.A.M.C.
Capt. A. H. Smith, R.A.M.C.
Col. F. S. L. Ford, C.M.G., Canadian A.M.C.
Lt.-Col. C. P. Templeton, Canadian A.M.C.
Capt. E. D. Gairdner, R.A.M.C., attached Rifle Brigade.
Lieut. F. G. Hack, R.A.M.C., attached Rifle Brigade.
Lt.-Col. A. E. Hodder, R.A.M.C.
Capt. R. W. Smith, R.A.M.C., attached Hussars.

DEATHS AMONG THE SONS OF MEDICAL MEN.

The following sons of medical men must be added to our lists of those who are reported to have fallen during the war :—

Second Lieut. F. M. Sutcliffe, London Regiment, killed in action, was the third son of the late Dr. J. Sutcliffe, of Clapham, Surrey.

Second Lieut. R. M. Hamilton, Cheshire Regiment, accidentally killed abroad, was the fifth son of Dr. Hamilton, late of Chester.

Second Lieut. (acting Capt.) D. W. Tonking, Duke of Cornwall's Light Infantry, died of wounds, was the son of Dr. J. H. Tonking, of Camborne, Cornwall.

Major R. Bolster, M.C., Royal Artillery, killed in action, elder son of the late Surgeon-General T. Bolster, R.N.

MENTIONED IN DESPATCHES.

The following are mentioned in a despatch, dated June 12th, 1917, dealing with operations near Basra in April, 1915 :—

Lieut. N. S. Jatar, I.M.S.; Temp. Lieut. W. B. Patel, I.M.S.; Capt. A. R. Thomas, I.M.S.; Asst.-Surg. (4th class) M. J. Nicholas, I.S.M.D.; Senr. Sub-Asst.-Surg. (1st class) Azhar Hussain, I.S.M.D.

FOREIGN DECORATION.

French.

Médaille d'Honneur des Epidémies en Argent.—Temp. Capt. (temp. Maj.) A. G. Whitehorne-Cole, R.A.M.C.

THE ARTIST AT THE FRONT.

Part I. of Vol. II. of Mr. Muirhead Bone's drawings, issued from the offices of *Country Life* and Messrs. George Newnes under the title of "The Western Front," has the same high standard of imagination and technique as its predecessors. The larger proportion of the etchings are coloured, with very pleasing results. It will be noticed that Mr. Muirhead Bone, after his visit to the munition works and the Grand Fleet, has returned to France, as the current issue of "The Western Front" is devoted to the battle of Arras, with illustrations of Bapaume, Peronne, Thiepval, and other points of interest in the great advance. The prefatorial description of the battle of Arras forms one of the finest stories of a battle that we have ever read even in these days of journalism through the medium of pens of acknowledged distinction dealing with unrivalled opportunities. We cannot attempt to single out for particular notice any of the pictures.

HOSPITAL FOR LIMBLESS SOLDIERS.—Princess Louise has recently opened Erskine House, near Glasgow, as a hospital for limbless soldiers with accommodation for 400 patients. Some 450 men have been already provided with limbs manufactured by Scottish labour. About £200,000 has been raised for equipment and endowment of the hospital.

BATTALION SANITARY STANDING ORDERS.

THE article which follows has been contributed by Captain H. W. BAYLY, R.A.M.C. (T.), M.R.C.S., L.R.C.P. Lond. :—

The regular officers of the Royal Army Medical Corps receive a thorough and practical education in sanitation and hygiene, but circumstances do not usually permit Territorial or temporary medical officers to acquire a similar knowledge and experience. Many general practitioners or recently qualified men join the Royal Army Medical Corps as temporary officers and become attached to battalions with but a hazy idea as to the scope of their duties and with a very superficial knowledge of the contents of the admirable handbooks on the subjects of sanitation and hygiene provided and issued by the Army medical authorities.

Sanitary Duties of Battalion Medical Officers.

The temporary Royal Army Medical Corps officer often leaves his practice with the idea that sanitation is the work of a specialist and that his army duties will consist of attending to regimental sick and dressing wounded under fire. He usually quite fails to realise that his most valuable and important work may lie in the path of preventive medicine.

It is of the utmost importance that he should realise his position as the last link in the wonderful chain of practical science and administrative organisation between the private soldier and the Director-General of the Army Medical Service. Headquarters do everything possible to ensure efficient sanitation of the different sectors, and the most up-to-date orders are issued supplementing the excellent orders and regulations contained in the handbooks; but the final responsibility very largely remains still with the battalion medical officer. He alone is in a position to see that these orders and regulations for the health of the men and the sanitation of the area occupied by them are carried out. He alone can obtain their active coöperation in this work.

However perfect such orders and regulations may be, they will avail nothing if the battalion medical officer fails to see that they are carried out. Only by the ceaseless care and energy of the battalion medical officer can efficient sanitation be enforced and maintained. Constant disappointment, frequent rebuffs, must not discourage him. Although he knows that as soon as he is beginning to get things straight his battalion will be moved somewhere else, still, he must remember that although his particular unit will not benefit from his labours the work is not lost, and some unit of the B.E.F. will benefit. He must never allow popularity to come for one moment before duty, and it is not always easy, especially for a young man, to insist on the necessity of some work which may not appear as a necessity to a non-medical mind burdened with responsibility of a purely military nature.

To most non-commissioned officers and men Army Orders, or even Divisional Orders, are remote from their life as a unit, and to them their battalion is their world. It therefore appears advisable that every battalion should have its own standing orders dealing with sanitation and hygiene. Such orders must be very simple and explicit or they will be evaded, and the excuse made that they were misunderstood, or ignorance will be pleaded. Lectures on sanitation must be given by the medical officer of the battalion by companies, in which the standing orders are gone through item by item, and the "why" and "wherefore" explained. The soldier must be made to see that the Standing Sanitary Orders are drawn up for his own good, and that they are not just the arbitrary and annoying whim of a faddy medical officer.

As battalion medical officers fall sick or become casualties their places are taken by others, and continuity in sanitary methods is liable to be interfered with; thus Battalion Standing Sanitary Orders would help in assisting continuity. Divisional orders dealing with questions of sanitation accumulate rapidly, and it takes some considerable time for a medical officer to master the voluminous file of old orders; also, especially during an attack, or if the medical officer and sick sergeant become casualties, the file of orders may be destroyed or lost, and a new medical officer would find the Battalion Standing Sanitary Orders a great help.

I drew up the following standing sanitary orders for rest camp, on the march, and trenches, and the commanding officer of the battalion to which I had the honour of being attached was good enough to have them published in Battalion Orders after they had received the sanction of my

Assistant Director of Medical Services. They are only an extract, in simple language that can be understood by the men, of the many admirable orders, rules, and regulations contained in the Army publications and orders. They are based on practical front-line battalion experience, and my hope is that they may serve as a useful guide to battalion medical officers who are new to their work. Doubtless they can be advantageously modified to meet varied circumstances and environments, but I think that if somewhat similar Standing Sanitary Orders were enforced in every battalion they would assist in the carrying out of the wishes of the higher commands as expressed in Army Corps and Divisional Orders.

BATTALION STANDING SANITARY ORDERS.

I.—REST CAMP.

A. *Conservancy.*

1. *Latrines.*—(*a*) *Type: Temporary.* Buckets or tins with post and rail seat. Front of tin to be 4 in. behind bar, with a tin gutter 8 in. broad leading from back of bar into tin. *Permanent.* Buckets with closed-in seats and with covers for holes. Where permanent latrines of other types have been constructed by previous units they may be used subject to the sanction of the medical officer. (*b*) *Disinfection:* Buckets or tins to be disinfected with chloride of lime. (*c*) Buckets or tins to be emptied at 8 A.M. and 3 P.M. and contents burned in closed destructor where possible, but otherwise buried at least 100 yards from any house, hut, tent, or bivouac. (*d*) Every man to cover excreta with dry earth (or sawdust where possible) after using latrine. (*e*) Men are strictly forbidden to relieve themselves except in latrines. (*f*) Latrine seat must be washed daily with cresol solution.

2. *Urinals.*—(*a*) Urine pits to be constructed according to orders of the medical officer. (*b*) One urine bucket or tin to be placed outside each hut or billet of every platoon for use during night only. (*c*) Urine tins to contain 3 oz. cresol solution. (*d*) Tins to be emptied into urine pits at 8 A.M. daily. (*e*) Men are strictly forbidden to urinate except into the tins, buckets, or urine pits provided.

3. *Incinerators.*—(*a*) *Type:* Where possible, closed incinerators of the Horsfall pattern should be built by the pioneers of the battalion for the destruction of excreta. They may be built of tins full of earth, puddled clay, and corrugated iron sheeting. Where excreta are buried, open incinerators may be used for the burning of rubbish. (*b*) One incinerator per company is required and one for headquarters. (*c*) Incinerators should be lit at 8 A.M. and kept well burning all day and fully charged before leaving duty at 4 P.M.

B. *Disposal of Refuse.*

1. *Food and hut refuse.*—(*a*) All remains of food, empty tins, rubbish, &c., to be collected immediately after each meal and placed in the receptacle provided. The platoon sergeant will be responsible for the collection of refuse. (*b*) The refuse receptacles will be emptied and contents removed by the sanitary squad at 9 A.M. and 2 P.M. and burned in the incinerator.

2. *Cook-house refuse.*—(*a*) A receptacle to be provided adjacent to each cook-house for the collection of "pig-tub" refuse. (*b*) Contents to be removed daily by local contract or to be burnt in the incinerator.

3. *Sullage water from cook-house.*—(*a*) A sullage pit of the type recommended by the medical officer to be made as near each cook-house as practicable. (*b*) The hay or straw filter-layer to be burned daily in the incinerator. (*c*) The sand, gravel, or ash filter-layer to be changed once a week and the fouled material that is removed buried. (*d*) The sullage pit to be used for greasy water only.

4. *Horse-dung.*—All horse-dung to be removed daily, either (*a*) by arrangement with local farmers; (*b*) by burning in the incinerator; or (*c*) by burial in a pit or by being covered with a 6 in. layer of fresh earth.

C. *Water and Food.*

1. *Water* (drinking and cooking).—Men are strictly forbidden to drink any water, or fill their water-bottles with any water, or use any water for cooking purposes, except that obtained from the water-carts, unless by permission of the medical officer as published in orders.

2. *Food.*—(*a*) Rations will be issued by non-commissioned officer or senior soldier in charge of each section, only sufficient rations for each meal being issued at one time. (*b*) All unopened tins of food to be kept in a cool place until issued. (*c*) All bread, biscuit, cheese, sugar, &c., to be kept in a dust- and fly-proof receptacle until issued. (*d*) Meat (fresh) to be kept in a dust- and fly-proof safe until issued. (*e*) Tins only to be opened immediately before consumption of contents. (*f*) Any unconsumed food reserved for future consumption, or any food, chocolate, sweets, &c., contained in a parcel from home, to be placed in a dust- and fly-proof receptacle provided or in *closed* mess-tins.

D. *Fly Prevention and Destruction.*

(*a*) All refuse left by previous units must be collected and burned in the incinerator. (*b*) All foul ground from which refuse has been removed must be sprayed with cresol solution or with a vermorel spray. (*c*) All wooden or paved flooring must be brushed out daily and washed once a week with cresol solution.

E. *Personal Cleanliness.*

1. *Ablution places.*—(*a*) To be washed down daily. (*b*) The soapy water to be directed by open drains into two pits in series separated by a trap. The first or cleansing pit to contain chloride of lime and the effluent to be run off from 9 in. below the surface of the scum into the second or soakage pit. (*c*) The scum to be skimmed off the cleansing pit at least once a week and fresh chloride of lime added.

2. *Baths.*—(*a*) *Permanent:* When possible every man will have at least one hot bath per week. Platoon sergeants will be responsible that the bath rolls of their platoons are correctly kept. (*b*) *Temporary:* Where permanent baths are not provided a temporary bathing place will be, if possible, established and use made of the local tubs and coppers that are available. This bathing place must be trenched and drained into two large sullage pits in series, as with ablution places. (*c*) *Bathing parades:* In rivers, streams, &c. Platoon sergeants will be responsible that the rolls for such parades are correctly kept.

3. *Washing and sterilisation of underclothes and blankets.*—(*a*) Shirts, vests, and pants should be washed at least once a fortnight; socks must be washed once a week. (*b*) These articles should, if possible, be sterilised in a steam steriliser once in six weeks. (*c*) In fine weather blankets must be exposed to sun and wind for at least one hour daily.

F. *Ventilation.*

1. *Billets.*—All windows to be kept wide open day and night during summer months except on weather side during a rain-storm. During winter months windows to be kept wide open for at least one hour daily.

2. *Huts.*—(*a*) Windows and ventilators to be kept open day and night. (*b*) During windy weather in winter, if the hut contains windows on two sides, those on the weather side may be closed. (*c*) If the hut has loose tarpaulin sides these will be raised for at least one hour per day unless there is heavy rain and wind. (*d*) Windows or ventilators must not be blocked with sacking or other obstacle to free ventilation.

3. *Tents.*—(*a*) Walls of tent to be rolled up during day when tent is unoccupied except during heavy rain or wind. (*b*) During fine warm weather tent door to be kept open at night.

II.—ON THE MARCH.

A. *Latrines.*—(*a*) At every place where the battalion stops for an hour or longer shallow trench latrines of the 1 × 2 × 3 type should be dug by the sanitary squad in the proportion of one for every company and one for headquarters. Latrines must be filled in before proceeding. (*b*) During short halts or when a man has obtained permission to fall out on the march to relieve himself, he should dig a small hole with his entrenching tool, and after easing himself should fill in the hole with earth.

B. *Urination.*—(*a*) At every place where the battalion stops for an hour or longer an open urine pit 3′ × 3′ × 3′ should be dug out and filled in before proceeding. (*b*) During short halts or when a man has obtained permission to fall out to pass water he should be careful not to urinate within 50 yards of any pump, well, stream, reservoir, or pond. (*c*) If the battalion falls out in a village the men should make use of the public urinals provided by the military or local civilian authorities.

C. *Refuse.*—All remains of food, empty tins, &c., must be collected and buried in the urine pits and latrine trenches before proceeding after a rest for meals.

D. *Water.*—(*a*) No water to be drunk under any circumstances whatever except from the water-bottles carried. (*b*) No water to be drunk without the permission of an officer. (*c*) No water, other than water-cart water, to be used for cooking unless the permission of the medical officer has first been obtained.

III.—IN THE TRENCHES.

A. *Conservancy.*

1. *Latrines.*—(*a*) *Type:* Tins with bar and gutter as in temporary rest camp. (*b*) *Disinfection:* As in rest camp. (*c*) Tins to be emptied into a shell hole, or other pit, at least 20 yards from trench, and covered with 1 foot of earth. (*d*) Latrine tins to be emptied and contents buried once every day and during hours of darkness only. (*e*) Every man to cover excreta with dry earth after using latrine. (*f*) Men to be strictly forbidden to relieve themselves in unused communication trenches or anywhere except in the latrines provided. (*g*) Latrine seats must be washed daily with cresol solution. (*h*) Occupied trenches to be provided with latrine accommodation every 300 yards. Communication trenches to be provided with latrine accommodation every 600 yards.

2. *Urinals.*—(*a*) Only water-tight tins to be used. (*b*) Tins to be raised up so that top level is 2 feet above ground level. (*c*) Tins to be disinfected with 3 oz. cresol solution. (*d*) Tins emptied as with latrines. (*e*) Accommodation as with latrines. (*f*) Men strictly forbidden to urinate in unused trenches, or anywhere except in the tins provided.

B. *Disposal of Refuse.*

(*a*) All refuse, empty tins, remains of food, &c., to be collected after each meal and placed in sandbag provided. Refuse must *not* be thrown over parapet or parados. (*b*) Refuse bags to be buried every night. (*c*) Any rubbish heap or foul ground that smells or attracts flies must be sprayed with creosol solution or a vermorel spray, and covered with fresh earth. (*d*) All refuse of any kind left littering the parapet, parados, or ground within 20 yards of a trench by previous occupiers of the sector must be removed and buried as soon as reasonably possible. (*e*) All greasy or soapy water must be poured into a hole and covered with fresh earth.

C. *Water and Food.*

1. *Water.*—(*a*) Men are strictly forbidden to drink any water or to fill their water-bottles with any water, except that supplied for their use by tank, pipe, or water-cart. (*b*) Well or pump water from adjacent houses must not be used for cooking unless the permission of the medical officer has been first obtained.

2. *Food.*—(*a*) Tins only to be opened immediately before consumption. (*b*) Any unconsumed food reserved for future consumption to be placed in a dust- and fly-proof receptacle, such as a closed mess-tin.

D. *Corpses.*

If, owing to position or decomposition, removal for burial is impracticable, the body, if within 30 yards of trench, must as soon as is reasonably possible be covered with 1 foot of earth or soaked with petroleum and burned.

ADDENDUM TO STANDING SANITARY ORDERS.

IV.—DUTIES OF SANITARY PERSONNEL.

1. The sanitary squad will be under the orders of the medical officer.

2. Routine hours of work in rest camp shall be 8 A.M. to noon and 2 P.M. to 4 P.M.

3. During the hours of work no man may absent himself from his duties.

4. Members of the sanitary squad will be excused all parades and fatigues with the exception when in trenches, of ration, water, and trench cleaning fatigues.

5. Two sanitary men alternately of each company will attend roll-call daily.

6. When on the march, in trenches, or on any special occasion (such as on arrival at, or departure from, a camp) the sanitary squad may be required to work before 8 A.M. or after 4 P.M.

7. Members of the sanitary squad will act as sanitary police and will report to the sanitary corporal, who will report to the medical officer, who will report to the officer commanding company every or any breach in the Battalion Sanitary Standing Orders, and they shall have authority to demand the name and number of any offender.

8. The medical officer will make a sanitary inspection of the camp or billets or trenches daily and instruct the sanitary corporal as to the work to be done.

9. The medical officer will give special lectures while in rest camp on sanitation to the sanitary squad at least once a month.

10. The sanitary corporal will be responsible to the medical officer for the carrying out of the Sanitary Standing Orders and the additional orders of the medical officer.

11. The medical officer will give occasional lectures on sanitation when in rest camp to the officers and men of the battalion, explaining the Standing Orders.

12. The duties of the sanitary squad shall consist of: (*a*) Preparing latrines, urine pits and tins, sullage pits, and refuse pits. (*b*) Attending to the same. (*c*. Collecting and burning all refuse and rubbish from the receptacles provided. (*d*) Disinfection of foul ground. (*e*) Reporting offences against Sanitary Orders.

Need of Constant Inspection.

In conclusion, I venture to insist on the urgent necessity of the battalion medical officer satisfying himself by daily inspection that his orders and the Battalion Standing Sanitary Orders are being carried out. It is quite useless giving orders if the orders are not backed up by frequent inspection. Nothing must be skipped, and it is as important to visit every trench latrine and dug-out as to make the daily round of billets and sanitary areas when behind the lines. The medical officer's daily visit to front-line trenches shows that he really believes in the importance of his teaching and helps to establish the friendly coöperation of the men. Unused communication trenches are apt to become insanitary if a watchful eye is not kept on them.

It is quite fallacious to think that a battalion medical officer has a lazy time except during a "push." On the contrary, if he performs all his duties efficiently he is busily employed nearly all his day, and especially so in rest camp, where his lectures on sanitation and first aid to officers, non-commissioned officers, and men, as well as to his own particular charges, the sanitary squad and stretcher-bearers, will be part of his routine week-day work. If a battalion medical officer complains that he is bored and has nothing to do, one can be very certain that he has failed to realise the scope of his duties and is not an efficient battalion medical officer.

RED CROSS GIFTS.—A menu card with drawings of penguins on the back by Captain Evans, of the *Broke*, has realised £1000 for the Red Cross. Mr. Walter Morrison has given a donation of £10,000 to the City of London Branch of the British Red Cross Society. £11,650 have been given by the British Farmers' Red Cross Fund for the purpose of meeting the expenses of the two hospital trains presented to the Red Cross by the Flour Millers of the United Kingdom.

URBAN VITAL STATISTICS.

(Week ended June 9th, 1917.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 17,000,000 persons, the annual rate of mortality was 12·7, against rates steadily declining from 18·5 to 12·7 per 1000 in the eight preceding weeks. In London, with a population exceeding 4,000,000 persons, the death-rate was 12·1, or 0·4 per 1000 above that recorded in the previous week; among the remaining towns the rates ranged from 4·5 in Hornsey, 5·3 in Newport (Mon.), and 5·4 in Northampton to 20·4 in Walsall, 21·0 in Gloucester, and 23·0 in Sunderland. The principal epidemic diseases caused 348 deaths, which corresponded to an annual rate of 1·1 per 1000, and included 208 from measles, 61 from whooping-cough, 45 from infantile diarrhœa, 22 from diphtheria, and 6 each from enteric fever and scarlet fever. The deaths from measles were 37 fewer than in the previous week, and caused the highest annual death-rates of 3·3 in West Hartlepool and in South Shields, 3·6 in Sunderland, 3·9 in West Bromwich, and 4·5 in Middlesbrough. The 636 cases of scarlet fever and 1082 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 10 and 21 above the numbers remaining at the end of the previous week. Of the 4116 deaths from all causes in the 96 towns, 134 resulted from violence. The causes of 24 deaths were uncertified, of which 3 were recorded in Birmingham and in Sunderland, and 2 each in Stoke-on-Trent, South Shields, and Gateshead.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual death-rate was equal to 14·9, against rates declining from 17·0 to 16·0 per 1000 in the three preceding weeks. The 325 deaths in Glasgow corresponded to an annual rate of 15·2 per 1000, and included 37 from whooping-cough, 32 from measles, 3 each from diphtheria and infantile diarrhœa, and 1 from scarlet fever. The 110 deaths in Edinburgh were equal to a rate of 17·3 per 1000, and included 7 from whooping-cough, 6 from measles, and 1 from infantile diarrhœa.

Irish Towns.—The 141 deaths recorded in Dublin were equal to an annual rate of 18·4 per 1000, and included 3 from measles, and 2 each from whooping-cough and infantile diarrhœa. The 101 deaths in Belfast corresponded to a rate of 13·4 per 1000, and included 2 from whooping-cough, and 1 each from enteric fever, measles, and infantile diarrhœa.

A MONTHLY RECORD OF ATMOSPHERIC POLLUTION.

COMMITTEE FOR THE INVESTIGATION OF ATMOSPHERIC POLLUTION: SUMMARY OF REPORTS FOR THE MONTHS ENDING

Dec. 31st, 1916.

Place.	Rainfall in millimetres.	Metric tons of deposit per square kilometre. Insoluble matter. Tar.	Carbonaceous other than tar	Ash.	Soluble matter. Loss on ignition.	Ash.	Total solids.	Included in soluble matter. Sulphate as (SO_3).	Chlorine (Cl).	Ammonia (NH_3).

There are no returns in these tables from Exeter, the work having been discontinued owing to the war, nor from the Metropolitan Stations, Victoria Park (December and January) and Wandsworth Common (December), on account of frost.

"Tar" includes all matter insoluble in water but soluble in CS_2. "Carbonaceous" includes all combustible matter insoluble in water and in CS_2. "Insoluble ash" includes all earthy matter, fuel, ash, &c. One metric ton per sq. kilometre is equivalent to: (*a*) Approx. 9lb. per acre; (*b*) 2·56 English tons per sq. mile; (*c*) one gramme per sq. metre; (*d*) 1/1000 millimetre of rainfall.

The personnel of public health authorities concerned in the supervision of these examinations and of the analytical work involved remains the same as published in previous tables.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

Deputy Surg.-Gen. P. B. Handyside to be Surgeon-General, and Fleet-Surg. W. Bett, M.V.O., to be Deputy Surgeon-General.

To be Temporary Surgeons: J. E. Jackson, J. E. G. McGibbon.

ARMY HEADQUARTERS STAFF: MEDICAL BRANCH.

To be Temporary Directors, Medical Services in India: Surg.-Gen. J. G. MacNeece, C.B., Army Medical Service; Surg.-Gen. T. J. O'Donnell, C.B., D.S.O., Army Medical Service.

ARMY MEDICAL SERVICE.

Col. A. E. Ross, C.M.G., Canadian A.M.C., to be Deputy Director of Medical Services, vice Col. G. L. Foster, C.B., Canadian A.M.C.

Lieut.-Col. F. S. L. Ford, C.M.G., Canadian A.M.C., to be Assistant Director of Medical Services, and to be temporary Colonel whilst so employed, vice Col. A. E. Ross, C.M.G., Canadian A.M.C.

Capt. G. H. R. Gibson, Canadian A.M.C., vice Lieut. Col. F. S. L. Ford, C.M.G., Canadian A.M.C., and Lieut.-Col. C. P. Templeton, Canadian A.M.C., to be Deputy Assistant Directors of Medical Services.

Lieut.-Col. Cecil A. Lane, R.A.M.C., from Supernumerary List, to be Colonel.

ROYAL ARMY MEDICAL CORPS.

Major D. P. Kappele, Canadian A.M.C., to be temporary Lieutenant-Colonel whilst holding appointment as Officer Commanding, Canadian Cavalry Field Ambulance.

J. Macpherson to be temporary Honorary Lieutenant-Colonel.

Temp. Hon. Capt. C. McNeil to be temporary Honorary Major whilst serving with the Scottish Red Cross Society.

Capt. H. Meggitt to be Major.

To be temporary Majors: Temp. Capts. A. E. H. Bennett, R. H. MacDonald, C. J. Marsh, W. H. Whitehouse, G. G. Greer.

Lieut. W. Brander is restored to the Establishment.

Major (temp. Lieut.-Col.) R. Corfe relinquishes his temporary rank on ceasing to command a field ambulance.

Major J. R. Williams relinquishes his commission on account of ill-health, and is granted permission to retain his rank and wear the prescribed uniform.

Capt. G. D. Freer relinquishes his commission on account of ill-health.

Temp. Capt. A. R. Taylor, Canadian A.M.C., resigns his temporary commission.

Temp. Capt. J. Brereton-Barry relinquishes his commission on account of ill-health.

SPECIAL RESERVE OF OFFICERS.

Capt. (temp. Major) W. M. Parham relinquishes his temporary rank on alteration in posting.

Lieutenants to be Captains: P. N. Cook, H. M. C. Macaulay.

To be Lieutenants: A. D. Gorman (from Glasgow University Contingent O.T.C.), A. H. Boon, R. McGregor.

TERRITORIAL FORCE.

Captains to be temporary Majors: D. Douglas-Crawford, J. Hay.

Lieutenants to be Captains: L. A. Williams, M. B. G. Sinnette, H. Vallow.

Temp. Capt. J. J. O'Neill relinquishes his commission.

TERRITORIAL DECORATION.

The King has conferred the Territorial Decoration upon the undermentioned officers of the Territorial Force, R.A.M.C.: Major A. Butler, Major A. C. Hartley, Lieut.-Col. W. G. Richardson, Major (temp. Lieut.-Col.) G. A. Troup, Major (temp. Lieut.-Col.) A. W. Anderson, Major R. B. Sidebottom (attached Cheshire Regiment), Major R. Brodie (attached Seaforth Highlanders), and Major Peter Paget (attached East Kent Regiment).

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

In the May number of the *Journal of the Royal Army Medical Corps* Colonel Andrew Fullerton, C.M.G., has a useful article on Injuries of the Bladder and Urethra in War, these lesions having received very little attention on the part of writers on military surgery during the present war; and Colonel Cuthbert S. Wallace, C.M.G., discusses the treatment of Gas Gangrene as seen at the Casualty Clearing Stations. While it is true that the disease is not so dangerous now as it used to be, because of the universal opening-up of wounds, the amount of trouble that it entails, and the amount of disturbance that it is necessary to inflict on a grievously wounded patient, makes the author of the communication long for some remedy other than surgical interference. With the object of showing the frequency and nature of the diseases of the ear, throat and nose met with in a T.F. General Hospital, Captain A. Brown Kelly contributes an article on statistics of the first 1000 of these diseases treated in the Fourth General Hospital, Stobhill, Glasgow, and Lieutenant-Colonel C. M. Wenyon and Captain F. W. O'Connor continue their joint inquiry into problems affecting the spread and incidence of intestinal protozoal infections of British troops and natives in Egypt.

THE LATE DR. C. E. TODD, OF ADELAIDE.—Charles Edward Todd, M.R.C.S. Eng., M.D. Brux., whose death at Adelaide is announced, was son of the late Sir Charles Todd, F.R.S., and received his medical education at St. George's Hospital, qualifying in 1882. Going out to Australia, he became surgeon to the Adelaide Hospital and to the South Australian Police Department, and was one of the best known operators in Australia. From 1901-2 he was president of the South Australian branch of the British Medical Association, and he held a commission as justice of the peace.

Medical News.

UNIVERSITY OF LONDON. — The Appointments Board was constituted by the Senate in 1909 for the purpose of assisting graduates and students of the University to secure appointments. About 2500 graduates and students have up to the present taken advantage of the Board's organisation, and a considerable proportion of them have secured appointments through its agency. The war has naturally impeded its general work, though not its usefulness. It is believed that after the war there will be much greater opportunities of successful work. Special efforts will be made to meet the employment needs of students and graduates who have served in the Army and Navy, and who may be temporarily displaced. All such graduates are invited to send their names to the secretary at once. The offices are at the University, South Kensington, S.W. 7.

THE LOCAL GOVERNMENT BOARD OF IRELAND AND DOCTORS OF MILITARY AGE.—The legality of the attitude of the Local Government Board, Ireland, in refusing to sanction the appointment to Poor-law offices of medical men of military age will shortly come before the courts for decision. A conditional order of mandamus was granted recently by the King's Bench on behalf of the Rathdown guardians, directing the Local Government Board to exercise their discretionary power of sanctioning the appointment of Dr. D. Boland to the position of medical officer. Sanction had been refused on the ground that the doctor was of military age, and the guardians submitted that there was no power of refusal when a man was qualified for the appointment. Several other boards are awaiting the decision in this case.

CENTENARIAN.—The King has sent a letter of congratulation to Mrs. Clutten, of Bungay, Suffolk, who has celebrated the 100th anniversary of her birthday.

THE office of the Assistant Director of Medical Service for the London Area of the Overseas Military Forces of Canada has been changed from 76, Strand, W.C. 2, to 13, Berners-street, W. 1.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The annual election of honorary officers and Council of the Royal College of Surgeons in Ireland took place on June 4th. There was no change either in the officers or in the members of Council. Lieutenant-Colonel William Taylor therefore now enters on his second year of office as President.

THE DENTISTS' REGISTER.—The official register for 1917 contains the names of 5512 dentists, of whom 11 are on the colonial and 16 on the foreign list. Of the 5485 United Kingdom dentists, 4134 hold licences in dental surgery, and 1351 are registered on their own declaration of being in bona-fide practice of dentistry. Of the former, 462 have additional surgical or medical qualifications, of the latter 7. The number added by registration during the year 1916 was 195, 8 were restored to the Register, and 144 were removed—120 on evidence of death, 0 on ceasing to practise, 23 under Section XII., and 1 under Section XIII. of the Dentists Act, 1878.

DEATH OF THE INVENTOR OF THE SIMPSON LAMP.—The death is announced on Tuesday, June 5th, of Mr. William Speirs Simpson, civil engineer, the inventor of the lamp which bears his name. The applications of this lamp in therapeutic practice were described in THE LANCET of Jan. 8th, 1916, p. 76, Jan. 29th, 1916, p. 240, Feb. 19th, 1916, p. 405, and March 4th, 1916, p. 508. The observations seem to prove that this lamp is not capable of producing penetrative rays but intensely actinic rays, which effect a marked destructive influence on bacteria. The poles of this arc lamp consist of wolframite, a tungsten compound, and the rays so produced are much more powerful than those given by the electrodes of the original Finsen lamp.

DONATIONS AND BEQUESTS.—Mr. and Mrs. G. W. Hayes, of Chester, have given £17,000 to Chester Infirmary for the purpose of endowing a ward in memory of their son, who was killed in action.—By the will of the late Mr. James Bruce, D.L., J.P., of Thorndale, Belfast, the testator left £1000 each to the Belfast Royal Hospital and the Society for Providing Nurses for the Sick Poor, Belfast; £500 each to the Belfast Nurses' Home and Training School, the Belfast Maternity Hospital, the Belfast Hospital for Sick Children, and the Belfast Consumption Hospital.—Miss M. E. P. Elliott, of Devonport, has bequeathed £2000 to Dr. Hingston's Convalescent Home at Devonport, and £500 to Dr. Hingston's Deaf and Dumb Institution, £1000 to the Plymouth Eye Infirmary, and £300 to the South Devon and East Cornwall Hospital, Plymouth.

HOSPITAL SATURDAY IN BELFAST.—The collection on Saturday, June 2nd, for the Royal Victoria Hospital, Belfast, has already realised £1512; and when all the outlying districts have made their returns the total is expected to reach at least £1700, which is the largest amount ever obtained.

ROYAL SANITARY INSTITUTE (90, BUCKINGHAM PALACE-ROAD, S.W.).—The next sessional meeting will be held at the Town Hall, Weston-super-Mare, on Saturday, June 30th, at 11.30 A.M., when Dr. W. G. Savage (medical officer of health for Somerset) will open a discussion on "Meat Inspection in Rural Districts." Dr. W. J. Howarth will be in the chair.

BENN ULSTER EYE, EAR, AND THROAT HOSPITAL, BELFAST.—At the annual meeting of subscribers to this hospital held on May 31st it was reported that during the past year there were 1560 new extern patients, while 470 were admitted to the wards. Five of the members of the medical staff have been granted commissions. The financial condition of the institution was sound, though it was stated that less than one-sixth of the income of the hospital was received from the public.

NATIONAL DENTAL AID FUND.—On Tuesday, June 12th, at the Mansion House, the Lord Mayor presided at a meeting of this fund, which is really an extension of the Soldiers' and Sailors' Dental Aid Fund. The movement, which is known as the Ivory Cross, will now give dental aid to discharged service men, the home army, the mercantile marine, and the necessitous poor. It has the support of the dental profession, and letters of approval were read at the meeting from, amongst others, Sir Arthur Newsholme (Medical Officer, Local Government Board), Sir StClair Thomson, M.D., Mr. W. H. Dolamore (President, British Dental Association), and Mr. W. Francis Mellersh (President, Metropolitan Branch, British Dental Association). The temporary offices of the fund are 10, Conduit-street, W. 1.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Parliamentary Session.

Both Houses of Parliament have now resumed after the Whitsun Recess.

HOUSE OF COMMONS.

THURSDAY, JUNE 7TH.

American Medical Men in France.

Sir GEORGE GREENWOOD asked the Under Secretary for War whether a large number of American doctors had recently been sent, by arrangement with the British Government, to treat British wounded soldiers in France; whether the American degrees of such doctors had been recognised for this purpose; whether he was aware that American osteopathic doctors held similar degrees and diplomas to those held by the doctors so sent to treat British wounded in France and were equally qualified to practise in the United States; and whether, in view of these facts, he would give permission to American osteopathic doctors, duly qualified in America, to attend to and treat British wounded in this country in cases where the patients might so desire.—Mr. MACPHERSON wrote in reply: A large number of doctors commissioned in the Army of the United States have been sent to Europe, and many of the most eminent practitioners in the United States are included. The American Government has commissioned the officers sent, and it is not proposed to look for any other security that these officers are qualified for the duties assigned to them.

Medical Re-examinations.

Answering Mr. JACOBSEN, Mr. MACPHERSON stated that no special or secret instructions had been issued to the Army medical authorities in connexion with re-examinations under the Military Service (Review of Exceptions) Act beyond those which had already been placed in the Library of the House of Commons.

Sterilised Meat.

Mr. FIELD asked the Secretary to the Local Government Board, in view of the fact that continental nations had for many years arranged conditions whereby partially tuberculised meat was sterilised, marked, and sold at a cheaper rate with benefit to the working consumers, whether he would make similar arrangements so that the meat food-supply might be fully availed of.—Mr. HAYES FISHER answered: I am in communication with the Ministry of Food with regard to this subject.

FRIDAY, JUNE 8TH.

Exchange of Prisoners.

Answering Mr. HUME-WILLIAMS, who asked whether an agreement had been entered into between France and Germany for the mutual repatriation of prisoners interned in Switzerland, and whether negotiations were pending for the conclusion of a similar agreement between this country and Germany, Mr. J. F. HOPE (representing the War Prisoners' Department) said: The answer to the first part of the question is in the affirmative. The agreement relates to prisoners of war who are found by a Swiss Medical Commission to be totally unfit for military service. The decision of this commission must, however, be confirmed by another commission of one military and two medical officers appointed by the captor Governments. An agreement has been concluded between H.M. Government and the German Government on similar lines. This agreement is not yet actually operative so far as we know. I should explain that the number of British prisoners of war who will benefit by the agreement is not likely to be considerable, and that a few men have already been repatriated from Switzerland on the ground that their health has deteriorated to such an extent since their transfer from Germany as to make them eligible for repatriation under the repatriation agreement already existing with Germany.

Mr. HUME-WILLIAMS: How soon will the agreement become actually operative?—Mr. J. F. HOPE: I imagine at once.

Mr. HUME-WILLIAMS asked whether any British and Turkish prisoners had yet been exchanged.—Mr. J. F. HOPE replied: No exchange of British and Turkish prisoners of war has yet taken place, nor, unfortunately, is it likely that any can take place in the immediate future. In a note which has just reached H.M. Government, after a delay of over two months, the Turkish Government pass over the proposals made to them for the exchange of 100 or 600 invalid prisoners a side as a first instalment and express the desire to revert to the arrangement reached last year, according to which all prisoners were to be exchanged who came up to a certain standard of incapacity. As it appears that the Ottoman Government only considers that 11 of the British prisoners of war who were in their hands in December last reach that standard it is clear that such an arrangement would prove wholly unsatisfactory. The Turkish Government is, therefore, now being pressed for a specific reply to the above-mentioned proposals for numerical exchange.

Sir J. JARDINE: Does the answer refer merely to British prisoners, or does it include Indians?—Mr. J. F. HOPE: Speaking from memory, I think it includes both.

Replying to a further question by Mr. HUME-WILLIAMS, Mr. J. F. HOPE stated that the United States Ambassador had left Constantinople, and the protection of British interests in Turkey was now in the hands of the Netherlands Minister. The United States Ambassador was not able, so far as was at present known, to take advantage, before leaving, of the promised permission to cause internment camps to be visited by his representatives. The Netherlands Minister had been requested to cause the camps to be visited, but it was not known whether he had been able to do so, and no reports had yet been received.

The Supply of Flavine.

General CROFT asked the Under Secretary for War (1) whether the properties of flavine were known to the medical profession in January last when a preliminary report was published in the *British Medical Journal*, and whether up to this time substantial quantities of flavine could not be obtained for the treatment of wounded soldiers in any hospital either at home or abroad; and (2) whether the War Office had received information as to the properties of the new antiseptic flavine; if so, what steps had been taken to obtain it; to whom was the order given for the supply of flavine and within what time was the order executed; whether there had been any delay in the execution of this order; and, if so, what was the reason.—Mr. MACPHERSON answered: The antiseptic properties of the substance referred to were described in a preliminary report published in the medical press in January last, giving the results of experiments with a small supply of this complex substance, specially made for these experimental purposes in a Government laboratory. Arrangements were made at the time for further trials in various military and other hospitals, and steps were taken with a view to a commercial supply being made available in the event of these trials proving sufficiently favourable. The trials had been in progress since January and the effects so far obtained are under careful comparison with those of other antiseptics. Before the substance can be placed on the market a licence must be obtained from the Board of Trade, as the substance was already the subject of a patent obtained before the war. Applications were made to the Board of Trade by various firms in the middle of last month. The hearing took place on May 24th, and I am informed that

the requisite licences are now being issued to five firms. There would therefore seem to be no doubt that the supply of the substance will be made available as rapidly as the several firms can produce it.

Medical Examinations for the Army.

Mr. ANDERSON asked the Under Secretary for War whether he was aware that statements of so serious a character regarding the treatment of men sent back for medical re-examination had been made before the Northampton tribunal that it had been agreed to hold a special joint meeting with representatives of the Medical Board; whether he knew that one solicitor stated that his clients had been treated like dogs; and whether investigations into these charges would be made by his department.—Mr. MACPHERSON replied: No specific complaints of the treatment by the Northampton Recruiting Medical Board have been received in the War Office. An officer of the department recently visited the Board and found that the men were being well treated and carefully examined. If my honourable friend will give me details of any particular case of alleged ill-treatment, I will have the matter investigated immediately.

Mr. RAMSAY MACDONALD asked the honourable gentleman whether his attention had been called to the passing for active and other forms of military service involving hard physical labour of men in Leicester suffering from valvular disease of the heart, chronic rheumatism, blindness in one eye, congenital physical weakness which had incapacitated from work for years, curvature of the spine, lameness, chronic bronchitis, and similar complaints; and whether he proposed to issue instructions to the Army doctors examining in Leicester which would prevent them passing such men into the Army.—Mr. MACPHERSON said in reply: I have noted what my honourable friend says of the Recruiting Medical Board at Leicester, but I must remind him that men suffering from definite disabilities which incapacitate them for general service are being classified in the lower categories for service of an auxiliary character. Every endeavour is made not to accept for service men whose disabilities are of such a character as to unfit them for rendering military service either of a general or an auxiliary character.

Mr. PRINGLE: Is the honourable gentleman aware that men are passed into low categories and then are immediately, on subsequent examination, passed into higher categories without any real examination of their physical condition?—Mr. MACPHERSON: I am told that is not the case.

Mr. PRINGLE: It is universal.

Mr. RAMSAY MACDONALD: Is it not a fact that men passed into the lower classes of these categories have got notice to sell up their businesses and dispose of what connexion they have got, and that the mere passing of the medical examination is so serious that it ought not to be done unless it means something from a military point of view?—Mr. MACPHERSON: I am told that no special instructions to give any such notice have been given by the War Office.

Mr. PRINGLE: Can the honourable gentleman explain why the R.A.M.C. doctors pass men without putting the stethoscope to them, especially seeing that the men have been certified to be suffering from valvular disease of the heart?—Mr. MACPHERSON: The honourable Member has made these charges previously, but he has not once submitted a specific case.

Mr. PRINGLE: I have.

Mr. MACPHERSON: I may inform the House that within the last week the Director-General has visited various centres from which complaints have come, and I can assure the House that thorough investigation of each complaint is being made.

Mr. PRINGLE: Whitehall is one of them.

Mr. RAMSAY MACDONALD: Has my honourable friend inquired into the long list of specific cases which I sent to him the other day, with names, addresses, and particulars of the men about whom I have made complaints?—Mr. MACPHERSON: Yes, I have ordered inquiries to be made into each individual case.

Answering Mr. CHANCELLOR, Mr. MACPHERSON said that it was not the policy of the War Office to enlist men for any form of service for which they were medically unfit.

MONDAY, JUNE 11TH.

Health of Troops in Mesopotamia.

Replying to Sir J. JARDINE, Mr. MACPHERSON (Under Secretary for War) wrote: The general health of the whole British Forces in Mesopotamia is satisfactory. There is an ample supply of hospitals, and no deficiency of nurses has been reported. The ratio of admission to hospital is less than double that of the troops in India in peace-time. The death-rate for all causes other than wounds in action is 4·5 per 1000 per annum, which is only fractionally higher than the peace rate in India. Owing to the arrangements made to induce local cultivators to grow crops under our control, it is reported that full and varied supplies of vegetables can now be obtained throughout the year at all the principal centres.

Medical Examinations for the Army.

Mr. NEEDHAM asked the Under Secretary for War whether men who had been discharged on account of valvular disease of the heart were entitled to claim to be totally or permanently disabled in accordance with the Military Service (Review of Exceptions) Act, 1917.—Mr. MACPHERSON replied: The answer is in the negative.

Mr. NEEDHAM asked whether the honourable Member would arrange in the case of men called up for re-examination under the Military Service (Review of Exceptions) Act the examining medical board should be supplied with the man's medical history of his service in the Army.—Mr. MACPHERSON answered: Instructions have already been issued reminding recruiting officers of the necessity of obtaining the previous documents of discharged soldiers.

Mr. PRINGLE: Will my honourable friend issue instructions that the medical history of the examined men shall be considered, because the documents are simply put aside?—Mr. MACPHERSON: I will have that inquired into.

TUESDAY, JUNE 12TH.

"Manipulative" Surgery.

Mr. PETO asked the Under Secretary for War whether he was aware that the deputation of the Parliamentary Injured Soldiers' Committee was informed by the Secretary of State for War on May 8th that he would consult the Law Officers of the Crown as to the acceptance of the offer of Mr Barker and other manipulative surgeons to give free treatment to injured soldiers; and whether he had received this information and could communicate it to the House.—Mr. MACPHERSON replied: The Law Officers have not yet given their opinion on the points submitted to them.

Mr. PETO: Will the honourable gentleman take some steps to get an early decision in this matter, seeing that a great interest is taken in it by 300 Members in this House?—Mr. MACPHERSON: I have asked that it should be expedited.

WEDNESDAY, JUNE 13TH.

Medical Arrangements in Mesopotamia.

Answering several honourable Members who asked when the report of the Mesopotamia Commission and the report made by Sir William Vincent's Commission on medical arrangements there would be published, Mr. BONAR LAW (Chancellor of the Exchequer) said: The report of the Mesopotamia Commission, which includes Sir W. Vincent's report, will be published immediately without alteration.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

HICKS, CHARLES E., M.R.C.S., L.R.C.P., has been appointed Medical Officer and Public Vaccinator to the Godmanchester District of the Huntingdon Union.

RIVERS, C., Certifying Surgeon under the Factory and Workshop Acts for the Redruth district of the county of Cornwall.

SALT, A. P., M.R.C.S., L.R.C.P. Lond., Certifying Surgeon under the Factory and Workshop Acts for the Totnes district of the county of Devon.

SIMPSON, J. W., M.D., F.R.C.P. Edin., to be one of the Medical Referees under the Workmen's Compensation Act, 1906, for the Sheriffdom of The Lothians and Peebles.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

BODMIN, CORNWALL COUNTY ASYLUM.—Female Junior Assistant Medical Officer. Salary £200 per annum, with board, &c.

BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN.—Female House Physician. Salary £150 per annum, with board, &c.

BRISTOL ROYAL INFIRMARY.—House Physician and House Surgeon. Salary at rate of £120 per annum, with board, &c.

DEVONPORT, ROYAL ALBERT HOSPITAL.—House Surgeon, unmarried. Salary £150 per annum, with board, &c.

DUMFRIES AND GALLOWAY ROYAL INFIRMARY.—House Surgeon.

ENFIELD, ROYAL SMALL ARMS FACTORY.—Assistant Medical Officer. Salary £438 per annum.

ESSEX COUNTY COUNCIL.—Assistant Tuberculosis Officer for holiday season. Salary £30 a month.

EVELINA HOSPITAL FOR CHILDREN, Southwark, S.E.—House Physician. Salary at rate of £160 per annum, with board, &c. Also Clinical Assistant in Out-patient Department.

FARNWORTH, NEAR BOLTON, TOWNLEYS MILITARY HOSPITAL. Female Assistant Medical Officer. Salary £383 5*s.* per annum, with rations, &c.

FOLKESTONE, ROYAL VICTORIA HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with board, &c

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—House Surgeon. Salary £250 per annum, with board, &c.

HAWKHEAD ASYLUM, Cardonald, Glasgow.—Senior Assistant Medical Officer. Salary £350, with board, &c. Also Junior or Temporary Assistant.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—House Physician for six months. Salary 30 guineas.

HOSPITAL OF ST. JOHN AND ST. ELIZABETH, 40, Grove End-road, N.W.—Resident Medical Officer.

MANCHESTER CHILDREN'S HOSPITAL, Pendlebury, near Manchester.—Two Female Resident Medical Officers, unmarried. Salary at rate of £100 per annum.

MIDDLESBROUGH, NORTH ORMESBY HOSPITAL.—Assistant to House Surgeon. Salary at rate of £100 per annum, with board, &c.

NEW HOSPITAL FOR WOMEN, Euston-road.—Female House Physician, Obstetric Assistant, Two House Surgeons. Salary £50 per annum, with board, &c. Also Resident Medical Officer at House of Recovery, New Barnet. Salary £60 per annum.

OLDHAM ROYAL INFIRMARY.—Third House Surgeon. Salary £225 per annum, with board, &c.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—House Physician. Salary £200 per annum, with board, &c.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.—Honorary Assistant Surgeon to Ear, Nose, and Throat Department.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—House Physician for six months. Salary £100 per annum, with board, &c. Also Temporary Assistant Physician Wednesday afternoons to see Out-patients. Lunch provided and travelling expenses.

ROTHERHAM HOSPITAL.—Junior House Surgeon. Salary £150 per annum, with board, &c.

SALFORD ROYAL HOSPITAL.—Junior House Surgeon. Salary at rate of £150 per annum, with board, &c.

SALFORD UNION INFIRMARY, Hope, Pendleton, near Manchester.—Female Assistant Resident Medical Officer. Salary £250 per annum, with rations, &c.

SHEFFIELD ROYAL INFIRMARY.—House Physician. Salary £120 per annum, with board, &c.

SHEFFIELD UNION HOSPITAL, Firvale.—Female Resident Assistant Medical Officer. Salary £250 per annum, with rations, &c.

SHREWSBURY, ROYAL SALOP INFIRMARY.—House Physician. Salary at rate of £200 per annum, with board, &c.

WEST LONDON HOSPITAL, Hammersmith-road, W.—Evening Clinic for Venereal Diseases. Clinical Assistants.

WESTMORLAND CONSUMPTION SANATORIUM AND HOME, Meathop, Grange-over-Sands.—Assistant Medical Officer. Salary £300 per annum, with board, &c.

WIGAN, ROYAL ALBERT EDWARD INFIRMARY AND DISPENSARY.—Medical Officer to take charge of Out-patient Department. Salary £250 per annum, with board, &c.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Bromley, Lisnaskea, and St. Agnes.

Births, Marriages, and Deaths.

BIRTHS.

BADGEROW.—On June 7th, at Hill-street, Knightsbridge, the wife of Major George W. Badgerow, F.R.C.S., Harley-street, W., of a daughter.

HILL.—On June 7th, at a nursing home, the wife of J. Percival Hill, M.A., M.D., of a daughter.

WELLS.—On June 6th, at Orleans Lodge, Winchmore-hill, N., the wife of Arthur G. Wells, M.B., B.S., D.P.H., M.R.C.S., L.R.C.P., Barrister-at-Law, of a son.

MARRIAGES.

DENNIS—CASSWELL.—On June 5th, at St. Mary's, Battersea, Captain Arthur Wesley Dennis, R.A.M.C., to Mary Theodora, eldest daughter of George Casswell, Gosberton, Lincs.

DICKSON—CUNNINGHAM.—On June 5th, at St. George's U.F. Church, Edinburgh, Captain Robert Milne Dickson, R.A.M.C., to Kate Wilson, daughter of the late William Cunningham, Dundee, and Mrs Cunningham, Merchiston Bank-gardens, Edinburgh.

FULLER—O'DONNELL.—On June 4th, at the Oratory of the Sacred Heart, Bournemouth, Captain R. Annesley Fuller, M.C., R.A.M.C., to Madeleine Mary, younger daughter of the late W. M. O'Donnell, F.R.C.S., of Glenreigh, Tipperary.

KEMP—DAVEY.—On June 6th, at Hampstead Parish Church, Charles Gordon Kemp, M.C., M.D., temp. Captain, R.A.M.C., to Kathleen Emily Davey, niece of Colonel J. and Mrs. Stollery, Hove.

WILLS—CROOK.—On June 7th, at Marlow Parish Church, Lieutenant Francis H. P. Wills, R.A.M.C., to Dorothy, eldest daughter of the late Peter Crook and of Mrs. Crook, of Borwick Lodge, Ambleside.

DEATHS.

BURN.—On June 7th, at Beechwood, Upper Tooting, S.W., William Barnett Burn, M.D. Lond., B.Sc. Lond., M.R.C.S., L.S.A., F.R.M.S., aged 73.

THORNE.—On June 11th, after a short illness, William Bezly Thorne, M.D., of Harley-street, W.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

THE BRITISH WOMEN'S HOSPITAL COMMITTEE.—This committee has forwarded to the Scottish Women's Hospitals a cheque for £10,000, which includes the profits of the season of *The Passing of the Third Floor Back*. The same committee has also given £500 to the Royal College of Nursing and £500 to the Hampstead and North-West London Hospital.

Notes, Short Comments, and Answers to Correspondents.

CURIOUS TOPOGRAPHICAL NAMES.

To the Editor of THE LANCET.

SIR,—We are becoming daily more familiar with many curious names of places and it is interesting to watch any which have a medical significance. The following is a little collection of names of altitudes and lakes in Canada which has some interest and arouses speculation as to their origin, and in some cases appear to reflect the influence of medical matters on the minds of people who likened places to medical fancies. In Alberta: Chin Hill, Knee hills, Medicine Lodge hills, Sulphur Mountain. In Assiniboia: Medicine Hat, Old-man-on-his-back plateau. In Athabaska: Knee Lake. In British Columbia: Bald Mountain, Eliza Ears, Face Mountain, False Ears, Family Humps, Finger Mountain, Golden Ears Mount, Heart Mountain, Nipple Summit, Nose Peak, Stone Nipples, Three Finger Peak, Thumb Peak. In Keewatin: Medicine Stone Lake, Woman Lake. In Manitoba: Bone Lake. In Ontario: Elbow Lake. In Quebec: Hair-cutting Lake, Tongue Lake. There are post-offices in Canada of the following names: Asbestos, Brown's Nurseries, Cap Santé, Elbow River, Eyebrow Hill, Finger Board, Gros Ventre (Assiniboia West), Hemlock, Henry's Corners, Heal, Mouth of St. Francis, North Gut, Science Hill, Skull Creek, Soda Lake, Sulphur, Thigh Hill, Tongue Creek.

In names familiar in connexion with the war Canada is rich, for there are Vienna, Berlin, Paris, London, and Bruxelles, Verdun and Namur, Flanders, Baltic, and Libau, Lemberg, Metz, and Krakow, Alsace and Lorraine, Lille and Amiens, Dieppe and Boulogne, four "French Villages," and three "French Rivers." There are Aldershot and Chatham, Dover and Harwich, Greenwich, Gosport, and Gibraltar, Egypte and Cairo, and Garden of Eden (near Tigris and Euphrates), while a prophetic instinct was shown ten years ago at least in the naming of Kaiser, Hun's Valley, and Gas Line, with Tanks (hill) 24 feet high in Prince Edward Island, and Marconi, not to mention "Round Up" and "New Germany." As a reminder of previous wars Canada has Mafeking, Ladysmith, Kimberley, Majuba Hill, Balaclava and Alma, Lucknow, Bannockburn, Waterloo, Trafalgar, Second Peninsula, while Nelson and Wellington and Washington are there with Collingwood, Havelock and Buller. Kitchener and French are there and a "Victoria Cross." Jeanne d'Arc, Bismark, and Moltke are there with Agricola and Germanicus. Asquith, Balfour, Earl Grey, and Carson are included. There is a psychology in names and I think the above will show some evidence of it.

I am, Sir, yours faithfully,

London, June 6th, 1917. ONOMATOLOGIST.

CAMPHORATED VASELINE OIL.

OWING to the fact that liquid vaseline is easier to sterilise than olive oil, certain French pharmacists have been tempted to utilise it in the preparation of camphorated oil. The substitution is not always devoid of consequences. Several instances were recently brought before the Paris Surgical Society of extensive and obstinate indurations which had resulted from injections of *soi disant* camphorated oil. In every instance inquiry elicited the fact that vaseline oil had been used in the preparation. Histological examination showed the indurations to consist in the main of inflammatory tissue containing numerous polynuclear cells. Physicians should not be tempted to prescribe, or dispensing chemists to substitute, liquid vaseline oil for the more assimilable vegetable oil.

PLAGUE AMONG RATS IN AN INDIAN ASYLUM.

Colonel W. H. B. Robinson, I.M.S., in his report for 1916 on the Lunatic Asylum at Nagpur (Central Provinces), gives credit to the work of a deputy superintendent, to whose administration he ascribes the fact that, though plague was raging all round and rats were dying all over the asylum, none of the inmates were attacked.

MEDICAL BARONETCIES.

To the Editor of THE LANCET.

SIR,—It may interest certain readers of THE LANCET to know that Dr. Frederick Taylor is the ninety-fourth member of the medical profession to receive the honour of the baronetcy. King James I., at the institution of the Order in 1611, offered the first patent to his physician, Dr. Henry Atkins. Dr. Atkins, however, refused the honour, probably on account of an onerous condition attached to it at that time—namely, the maintenance for three years in the province of Ulster of 30 soldiers. The premier medical

baronet was Sir Edward Greaves, so created in 1645 by Charles I., to whom Dr. Greaves was physician-in-ordinary.

The number of medical baronets created by succeeding monarchs is as follows: By Charles II., 5; by George I., 1; by George II., 2; by George III., 17; by George IV., 5; by William IV., 5; by Victoria, 38; by Edward VII., 11; by George V., 9. "Jacobite Baronetcies" were conferred by "James III." upon two of his medical adherents. Inherited baronetcies have been held by 19 medical men.

I am, Sir, yours faithfully,

S. D. CLIPPINGDALE.

Holland Park Avenue, W., June 9th, 1917.

A QUAINT RHYMING CIRCULAR.

THE following extract from the *New York Packet* of Oct. 11th, 1784, is an interesting memento of the time when rhyming circulars and catalogues were issued—an accomplishment almost impossible now, we should imagine, with the multiplicity of sesquipedalian terms:—

At the Medical Pillar, corner of Wall street and Hanover-square, head of the Coffee-house bridge, Smith, Moore & Co. have for sale, a general Collection of the Materia Medica, Botanical, Clymical and Galenical.

Produc'd from field, from fire, and pot, [and root,
Each compound, mineral herb, Radex Colomb; Glyz: Gent: Valerian;
Cortex Semarub: Winterian;
Rochelle and Glauber's salts, and shell Lac;
Gums of Greek name and Arabac,
Galb: Kino: and Opoponax,
Opium, Juniper, and Styrax,
Camphor, Thus, Aloes, Gualac,
Myrrh, Gamboge, Scammony, Ammoniac; [you'll find
Fine flowers of Su'phur: here
The red Bark too of purest kind;
Magnesia, Allum, Cream of Tart,
Tamarinds, Coral, and Sal Mart:
Syrups and Extracts, Seeds and Senna, [Manna,
Musk, Saffron superfine, and
Caraway, Fennel, Spanish Flies,
Cam'mile, Cinnabers, and Crab's-eyes, [white,
Best leathern skins, the red and
And Candied-sugar brown and light;
Figs, Sago, Salop, and Tin-foil,
Pearl-barley, Starch, and Olive Oil,
Spice, Raisins, Currants, Surgeon's tow, Wax,
Salt-petre, Bismuth, Potash, Borax,
Green oil-cloth, Sponge, Alleppo-galls, [balls,
Corks, Acqua Fort: Zinc: Liqu'rice
Balsam Canadian, and Tolu,
Capivi, Gilead, and Peru,
The purest Æther, Eau du Luce,
Liquor by Hoffman, Lemon Juice,
Isinglass, and Hartshorne shavings,
To clear your coffee or wine-leavings, [Viv.
Strong Oil of Bays, and Argent.
For Hessian vermin left alive.

THE SALICYLIC TREATMENT OF RHEUMATISM.

To the Editor of THE LANCET.

SIR,—Being surgeon in charge of H.M.S. *Salamander* off the north coast of Australia, Surveying Service, in 1862, I had a case of acute rheumatism and, being a thousand miles from a drug-store, I wanted to prescribe quinine but found we were out of it and had only, casually, a bottle of salicin, then hardly used in medicine. This I administered with good results. I think I must have been thus the discoverer of the salicylic treatment of rheumatism.

Perhaps some curious reader might enlighten me, as I think it was the first instance of that great anti-rheumatic remedy being used.—I am, Sir, yours faithfully,

Valparaiso, Chili, April 26th, 1917. RICHARD CANNON, M.D.

*** The late Dr. T. Maclagan stated (THE LANCET, 1876, i., 342) that the idea of treating acute rheumatism with salicin occurred to him in November, 1874.—ED. L.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETING OF SECTION.

Thursday, June 21st.

DERMATOLOGY (Hon. Secretaries—J. E. R. McDonagh, Henry MacCormac): at 5 P.M.
Cases (at 4.30 P.M.).

LONDON DERMATOLOGICAL SOCIETY, St. John's Hospital, 49, Leicester-square, W.C. 2.
TUESDAY.—4.30 P.M., Annual Meeting. Election of Officers and Council. Clinical Cases will be shown by Capt. Underwood, R.A.M.C., Capt. W. Griffith, R.A.M.C., Dr. J. L. Bunch, Dr. W. K. Sibley, Dr. G. P. Mitchell, and Dr. M. Dockrell.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital, Hammersmith-road, W.
FRIDAY.—8 P.M., Reception. 8.15 P.M., Cavendish Lecture:—Capt. A. Macphail, C.A.M.C.: A Day's Work. Annual Conversazione.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.
TUESDAY AND THURSDAY.—5 P.M., Croonian Lectures:—Lieut.-Col. J. G. Adami, A.D.M.S.: Adaptation and Disease. (Lectures II. and III.)

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.
MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.
TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.
WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.
THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.
FRIDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.
SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY.—Clinics:—10.30 A.M., Surgical Out-patients (Mr. B. Gillespie). 2.30 P.M., Medical Out-patients (Dr. T. R. Whipham): Gynæcological Out-patients (Dr. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).
TUESDAY.—2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. Howell Evans); Nose, Throat, and Ear Out-patients (Mr. C. H. Hayton). Radiography (Dr. Metcalfe). 3.30 P.M., Medical In-patients (Dr. A. J. Whiting).
WEDNESDAY.—Clinics:—2.30 P.M., Throat Operations (Mr. C. H. Hayton). Children Out-patients (Dr. T. R. Whipham); Eye Out-patients (Mr. R. P. Brooks); Skin Out-patients (Dr. H. W. Barber). 5.30 P.M., Eye Operations (Mr. R. P. Brooks).
THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patients (Dr. A. J. Whiting); Surgical Out-patients (Mr. Carson); Radiography (Dr. Metcalfe). 3 P.M., Medical In-patients (Dr. R. M. Leslie).
FRIDAY.—2.30 P.M., Surgical Operations (Mr. Howell Evans). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. B. Gillespie); Eye Out-patients (Mr. R. P. Brooks).

ROYAL INSTITUTE OF PUBLIC HEALTH, Lecture Hall of the Institute, 37, Russell-square, W.C. 1.
Course of Lectures and Discussions on Public Health Problems under War and After-war Conditions:—
WEDNESDAY.—4 P.M., Lecture X.:—Dr. E. J. Russell: Food Production in Peace and War. Followed by a discussion.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.*

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C. 2.

MANAGER'S NOTICES.

ALTERATION IN THE PRICE OF "THE LANCET."

INCREASED war expenses and cost of production necessitate an increase of the price of THE LANCET. Commencing with the new year, the price was raised to 8*d*. The rates of subscription remain as revised in October.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C. 2, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION is published in time to catch the weekly Friday mails to all parts of the world.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given on page 4.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied.

METEOROLOGICAL READINGS.

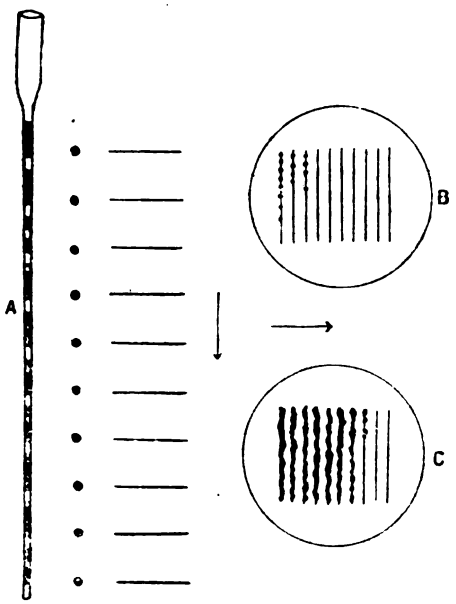
A Lecture

ON THE

TREATMENT OF WAR WOUNDS.*

SUPPLEMENTED BY ADDITIONAL MATTER RELATING TO ANTISEPTICS AND THE METHOD OF CARREL.

BY COLONEL SIR ALMROTH E. WRIGHT, M.D., C.B., F.R.S.,



A CONSULTANT PHYSICIAN TO THE BRITISH ARMY IN FRANCE.

WE are wont to classify the patients in our military hospitals into sick and wounded. In reality all, or nearly all, are suffering from bacterial infections. And the essential difference between the sick and the wounded lies in this, that the sick are suffering from infections spontaneously contracted, the wounded from infections induced by mechanical injuries. My theme is the treatment of this latter class of infections. They are distinguished by certain quite special features.

In spontaneous infection we have to deal with microbes which have fought their way into the body, and generally only a single species of microbe will have done this. In wounds we have microbes mechanically driven in, and every sort of microbe which exists in external nature may thus be introduced.

Furthermore, the disposition of the microbes in war wounds is fundamentally different from that in ordinary surgical wounds. In war wounds the infection is disposed in part upon lacerated raw surfaces; and in part it is carried deep into the substance of the tissues. Moreover, the infected lacerated surfaces are left denuded of skin and exposed to injurious external influences; and the infection which is carried down into the tissues is left as a buried infection. Now there is in ordinary surgical operations nothing at all comparable to this. The surgeon never leaves cut surfaces naked and exposed, or a buried focus of infection unopened.

FIG. 1.

Method of pyo-sero-culture.—A, Pipette which has been implanted by the wet-wall method, and has then been filled in by the wash and after-wash procedure with unit volumes of serum. By the side of the pipette to the right are ranged a series of drops representing the series of unit volumes of serum blown out in order from the pipette, and, finally, to the right of the drops are a series of lines representing linear implantations made upon agar. B, Results of the series of linear implantations made with the unit volumes of the patient's serum. C, Results of the series of linear implantations made with the unit volumes of the normal serum which was used as a control.

* In its original form this lecture was delivered at the Royal Institution on March 9th, 1917.

This will have brought it home to you how especially difficult are the conditions which have to be dealt with in the infected war wound. But let me before embarking upon the question of their treatment, first tell you something about the natural agencies by which the inroads of microbes are combated. You are, of course, aware that we are guarded against microbic infection by our blood fluids and our white blood corpuscles.

THE BODY FLUIDS.

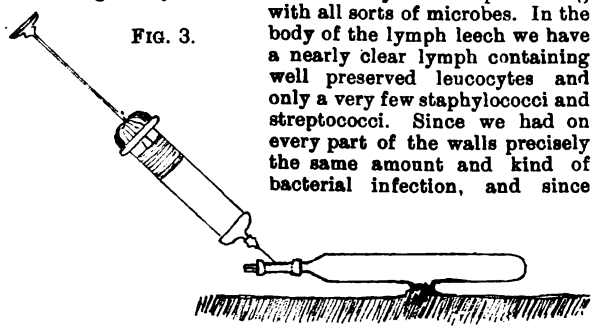
Let me begin with the blood fluids, and let me take you directly to the following experiment. I call it the experiment of *pyo-sero-culture*—i.e., the experiment in which we implant pus into serum to see which of the microbes of the wound can grow in the blood fluids.

We procure for our experiment a suppurating wound. We take from it a specimen of pus containing a large variety of different organisms. At the same time we take from the patient's finger a sample of blood; and we take a specimen also of our own. When the serum has issued from the clot we take a capillary pipette, fit a rubber teat to the barrel, and inscribe a mark upon the stem at about say one-third of an inch from the tip. We now aspirate a little pus into the stem, drawing it up only as far as our fiducial mark, and blowing it out again leave a wash of pus upon the walls. This done, we sterilise the tip of the pipette, and then aspirate into the stem a series of unit-volumes of serum, dividing each volume off from the next by a bubble of air. The pipette when filled in this manner presents the appearance shown in Fig. 1; and we have now in the proximal end our first and heaviest implantation of pus, and in the distal end our last and lightest implantation. The pipette is after this placed in the incubator to allow every microbe which is capable of growing in serum to do so. After an interval of six or more hours we proceed to our examination. What we do is to blow out our series of unit-volumes of serum in separate drops and examine under the microscope; or, better, we plant out a sample of each drop upon a separate seed-bed. Here in B and C you have the results of such culture represented diagrammatically—the meagre crop in B being that obtained with the patient's serum and the more copious crop in C being that obtained with normal serum.

FIG. 2.

A portion of a pyo-sero-culture planted out upon an agar slant divided up by furrows into a series of seed beds.

And you have in the next figure (Fig. 2) a drawing of an agar tube implanted from a pyo-sero-culture made with the serum of a wounded man. In the upper part of the agar tube you see two seed-plots implanted from the distal portion of the capillary stem. These have remained sterile. In the middle of the tube you see three plots implanted from the unit-volumes of serum which occupied the middle region of the capillary stem. These have grown colonies of only one species of microbe—the streptococcus. At the bottom of the tube you see seed-plots implanted from the proximal end of the capillary stem. These are over-grown with colonies of staphylococcus. But no doubt interspersed with and overgrown by these are also colonies of streptococci. If instead of cultures from the patient's serum, I had been showing you here cultures from normal serum, what you would have seen would have been a much larger number of fertile seed-plots, and the seed-plots implanted from the proximal end of the pipette would have shown a large assortment of different colonies.



We learn from such experiments three lessons: *first*, that in the uncorrupted serum in the distal region of the pipette only two species of microbes from the wound can grow and multiply; *secondly*, that in the corrupted serum in the proximal end of the pipette all the microbes of the wound can grow; and, *thirdly*, we learn from a comparison of the

wounded man's serum with the normal serum that the former offers more resistance to microbic growth, and is less easily corrupted by the addition of pus.

Cause of the Corruption of the Serum.

Experiments of this kind clearly do not tell us the cause of the corruption of the serum. It may be due to some chemical addition to the serum or to something special in the character of the bacterial implantations. This point we can clear up as follows. We go back to our very septic wound. We clean it out carefully by syringing. That leaves us with a wound cavity clean but still abundantly infected. We then take the little cupping apparatus which is shown in Fig. 3. We apply it to the walls of the wound, using light pressure. Then, puncturing the attached rubber tube with the needle of a hypodermic syringe, we withdraw the contained air, and leave our lymph leech *in situ* adhering by negative pressure till the time for redressing the wound comes round. When we now go back to our wound we find there two quite different discharges. We have in the general cavity of the wound a thick pus containing many broken-down leucocytes and pullulating with all sorts of microbes. In the body of the lymph leech we have a nearly clear lymph containing well preserved leucocytes and only a very few staphylococci and streptococci. Since we had on every part of the walls precisely the same amount and kind of bacterial infection, and since

FIG. 3.

Lymph leech in position, showing technique for exhausting the air.

we are in each case dealing with the self-same lymph and leucocytes, this difference of results would seem to be due to our having in the lymph leech, owing to the negative pressure employed, a larger proportion of blood fluids.

But with this the problem is, as you see, only incompletely resolved. We have learned that the corruption of the discharges is not determined by the nature of the bacterial implantation; we have reason to think it is hindered by a larger afflux of lymph; and it looks as if it might have something to do with the breaking down of the leucocytes, but we have not yet put our finger upon the particular element that takes away from the serum its power of inhibiting microbic growth, converting it into a congenial pabulum for all manner of micro-organisms.

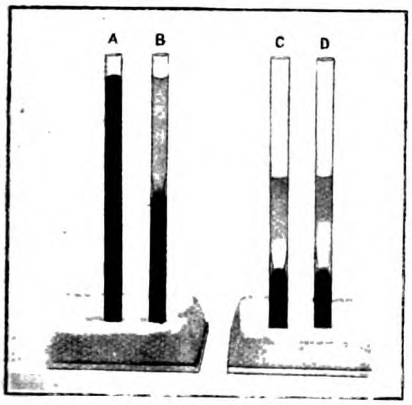
Let me in this connexion invite you to consider, for that may perhaps put us on the path for the solution of our problem, a scheme of classification of the albuminous substances. I would propose to classify them from the point of view of their capacity to furnish pabulum for microbes, and to distinguish three classes of albuminous substances. First, would come *digested albumens*. It is a familiar matter that these furnish very congenial pabulum for microbes. In the form of peptone we use them for all our artificial cultures. A second category of albumens would be *native albumens*. Muscle, milk, and eggs furnish such albumens. These are not like digested albumens, directly assimilable. Before they can be assimilated, either by ourselves or by microbes, they must be broken down into simpler elements by digestion. We ourselves, and a certain number of microbes also, are furnished with digestive ferments which convert native albumens into pabulum. There is yet a third class of albumens. I would venture to call these *defended* or *protected albumens*. These cannot, like the digested albumens, be directly assimilated. Nor can they, like the native albumens, be directly digested. They are specially defended against the attack of digestive ferments. The albumens of the serum may be ranged in this class of "defended albumens." It is well known with respect to serum that it has a power of neutralising digestive ferments,[1] and we express that fact by saying that the serum has an antizymotic, and in particular an antitryptic, power. You will, perhaps, not immediately perceive that the fact that the serum is antitryptic in any way elucidates our problem. But let us take that fact and put it in another way and then consider. Let us, instead of saying that the serum has an antitryptic property, say that it has a power of preventing its constituent albumens being converted into pabulum for microbes, and immediately, as I think, light is projected upon our problem. For once we envisage the facts in that way we are immediately impelled to inquire whether the serum's power of inhibiting bacterial growth may not be due to its power of neutralising digestive ferments, and whether the corruption of the lymph in the cavity of the wound may not be due to a collapse of its defence against proteolytic attack.

That is a point which is very easily settled by direct experiment. And let me now show you what happens when we add trypsin to a serum which has been implanted with microbes. I have here two tubes of a serum implanted two days ago with a minute quantity of pus containing a variety of different microbes. To the one I added trypsin, the quantity added being less than that required to neutralise its antitryptic power. The other tube of the implanted serum served as a control. Both tubes were then placed in the incubator. And you see the difference. The trypsinised serum is turbid with microbic growth. That is, we have here exactly the same result as that obtained in the sero-pyo-culture experiment in those volumes of serum which were heavily implanted with pus; and the same result also as was in the lymph leech experiment obtained in the pus of the wound cavity. Our control serum has, as you see, remained almost perfectly clear. That is the same result as was obtained in the sero-pyo-culture experiment with our lightly implanted serum, and again in our lymph leech experiment in the cavity of the lymph leech.

All this, as you see, points to the corruption of the blood fluids being due to a loss of antitryptic power. This view wins further support from the following facts: 1. There is in every suppurating wound, as we shall presently see, a source from which trypsin can be derived. 2. Blood fluids which inhibit microbic growth are strongly antitryptic; and blood fluids which we find teeming with microbes are tryptic. 3. We have in the blood of every wounded man a markedly increased antitryptic power (you saw in our pyo-sero-culture experiment what results from this); and in the blood of heavily wounded men on an average a three- or four-fold increased antitryptic power. That clearly teaches that the body when endangered takes steps to protect itself non-specifically against all microbic infections of the blood fluids.

THE LEUCOCYTES.

I now pass on to consider the leucocytes and the part they play in the destruction of microbes. You already know with respect to leucocytes that they can emerge from the blood-vessels, burrowing their way out through small pores in the capillary walls; that they make their way to every focus of infection; that they ingest microbes when these have first been prepared by the action of the blood fluids; and, finally, you know that the leucocytes can, if things go favourably, digest and dissolve the ingested microbes. There would by consequence in connexion with the leucocyte be three functions to study. First would come emigration, then phagocytosis, and then intracellular digestion. Emigration has up to the present been studied only in the interior of the organism. You will realise that means that it has been studied only in difficult setting and in the presence of all sorts of disturbing factors, and you will appreciate that we want now a new and better technique. For we require for the treatment of the infected wound to find out how best to call out the leucocytes; and how, when occasion requires, to restrain their emigration.



I have in connexion with this a technique to describe to you, but first I want you to appreciate what we can and what we cannot expect from leucocytes in the matter of locomotion. Leucocytes can, we know, make their way out through small openings. They can also travel over any ordinary surface. They can edge their way along faster when lightly compressed between two surfaces. They can crawl along strands, creep through a meshwork, and climb a scaffolding. But they are unable to climb a vertical glass wall. And again, they are unable to swim, and so once they

[1] Let me here incidentally call attention to the fact that the application of horse serum will prevent and very effectually relieve the digestive erosion of the skin which is in enterostomy of the upper part of the small intestine produced by the outflow of pancreatic juice.

get into open fluid they simply go to the bottom. If we are anxious to find something to which we may compare them we may liken them to very minute slugs crawling along surfaces and climbing trellises, but brought up short by any considerable barrier of fluid.

All these points must be considered if we want to arrive at a technique for the experimental study of emigration, using for the study of emigration specimens of blood withdrawn from the body. The containing blood vessel can in certain respects be imitated by a glass tube, and we can, to facilitate observation, use tubes drawn out flat, such as shown in Fig. 4. But our artificial capillary differs from the natural one in having impermeable instead of permeable walls. This, of course, makes emigration through the walls impossible. None the less, we can in these tubes study emigration. We can institute races for leucocytes along the length.

FIG. 4.

Drawing of four flattened capillary tubes—A, filled in with blood; B, a similar tube after centrifugalisation showing above the "white" and below the "red clot"; C and D, similar tubes after incubation. Leucocytic emigration visible to the naked eye as opaque white bands occupying the lower portion of the white clots. In D, where physiological salt solution had been imposed upon the white clot, the band of emigration is much broader than in C.

But first certain preparations must be made. The course must be cleared of all obstructions—i.e., the red corpuscles must be got out of the way. Next the leucocytes must all be brought back behind the scratch line, and we must provide a scaffolding for the leucocytes to climb. This can all be arranged. We fill in our flat emigration tubes with blood and seal them at one end. We then, by centrifuging, bring the blood fluids to the top and the corpuscles to the bottom. The lighter leucocytes will now have arranged themselves in a layer immediately above the red, and presently the supernatant fluid will clot and the meshwork of fibrin will then provide the scaffolding we require. We can now impose upon the clot—let me for convenience call it the white clot—any chemical agent we please and let it slowly diffuse down towards the leucocytes; or if we want to study the effect of bacterial infection, we can introduce microbes into the blood before we fill it into the tube, or as an alternative fill our blood into tubes whose walls have been implanted with microbes. Finally, we set our experiment going by placing our emigration tubes in the incubator—that is, we supply to our leucocytes the necessary warmth. And we can at any moment take stock of what is occurring in our tubes by examining with the naked-eye or with the low power of the microscope through the walls. Also by a very simple technique we can extract the clot from the tube and mount and colour it, so as to bring everything clearly into view under the high powers of the microscope.

Emigration of Leucocytes: Facts with Practical Application.

I must limit myself to showing you in connexion with emigration a few outstanding facts which have a practical application to the treatment of wounds. Let me begin with the naked-eye appearances. We have in Fig. 4, C and D, emigration tubes containing centrifuged blood which have been in the incubator for about eight hours. In C—the control tube—we have centrifuged blood to which no addition has been made. In D some weak salt solution has been imposed upon the white clot. The emigrating leucocytes are visible to the eye in the form of a slightly opaque white band extending upwards from the red into the white clot. You see that in D the corpuscles have climbed higher than in C.

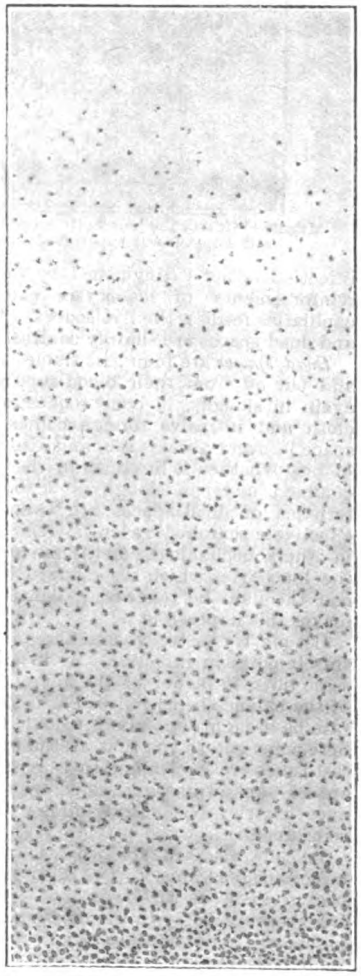


Fig. 5 shows what such a band of emigrating leucocytes looks like under the microscope. Instead of the leucocytes being all, as you will see in the next, congregated together behind the starting line, they here are actively emigrating, the more active out-distancing the others in the race.

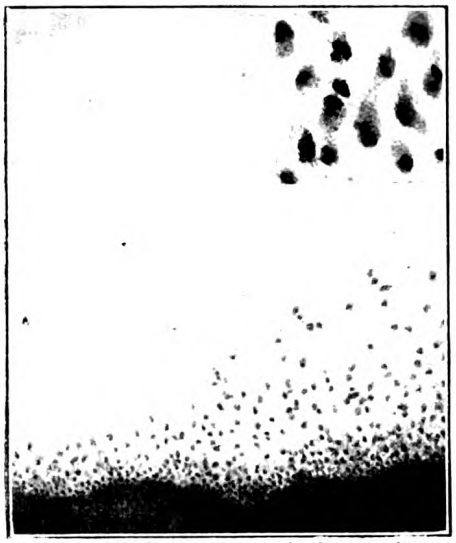
Fig. 6 shows what happens when 5 per cent. salt solution is imposed upon the blood. That salt passes down by diffusion and arrests emigration, and I want you to notice in the one corner of the figure (and more clearly in the inset) that the few white corpuscles which were beginning to emigrate when the salt solution overtook them are broken up and destroyed. We shall presently appreciate the significance of that fact.

I next show you what happens when microbes have been implanted into the blood. Those microbes—supposing always that they are the sort that can proliferate in blood—grow out into colonies. In Fig. 7 is shown what happens when an excessive implantation has been made, and the bacterial colonies come up very thickly in the blood. You see here that emigration is entirely arrested. If that were to happen in infected tissues it would mean that the organism was there giving up the combat against the microbes.

In Fig. 8 we have again streptococcus implanted into the blood, but this time it is a much more sparing implantation. And here, as you see, the leucocytes are carrying out a raid against the microbes, each leucocyte ingesting and filling itself full with microbes.

FIG. 5.

Magnified view of the band of leucocytic emigration seen in Fig. 4, D.



In Fig. 9 I show you what happens when we make into the blood a very heavy implantation of the gangrene bacillus. Here in the neighbourhood of the leucocytic layer things are for the moment going well for the leucocytes, for they are actively phagocyting. But farther away from that layer there are very numerous colonies of the gangrene bacillus, which are growing unimpeded. The omens are consequently unfavourable. You can see in your mind's eye what is going to happen. In the first place, all further emigration of leucocytes is going to be arrested. And, in the second place, the leucocytes which have already emigrated and ingested microbes will, instead of successfully digesting them, be gradually poisoned by bacterial toxins. And when the leucocytes are killed, their digestive ferment—you will remember my telling you that it would shortly appear that trypsin was at hand in every wound—passes out into the serum. By that, the serum will, as we have seen, be converted into a medium in which microbes can grow and pullulate.

DISTINCTION BETWEEN "LIVE" AND "DEAD" SPACES.

But we must now come back from these general questions to that of the treatment of the wound. Let me begin by explaining to you—for important questions of treatment hinge upon this—the distinction between "*live spaces*" and "*dead spaces.*"

In the lacunæ of vascularised tissues we have *live spaces*. In these we have optimum conditions for resistance to bacterial infection. We have here an antibacterial lymph; and this is continuously secreted and moved along so that all corruptive changes would be continuously antagonised and remedied. Again, we have in live spaces ground that can be effectively searched by leucocytes, and if the bacterial

FIG. 6.

Magnified view of the leucocytic layer in the case where strong salt solution was superposed upon the white clot.

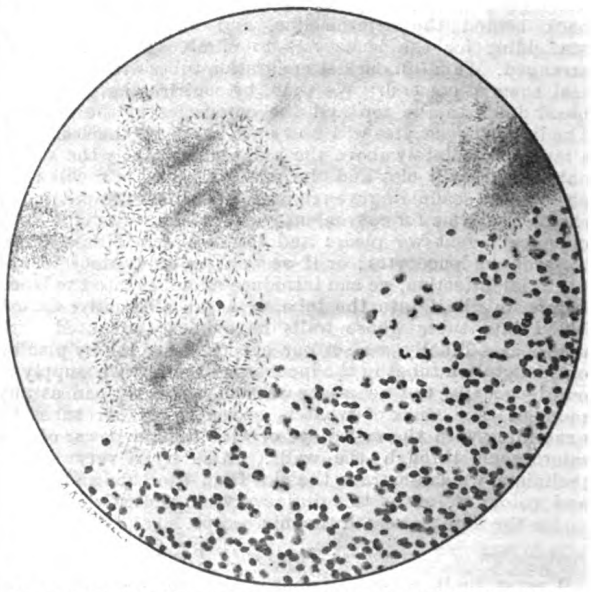
infection is not extinguished by the first leucocytic attack reinforcements of leucocytes can be supplied by the capillaries feeding the live spaces. In all these respects live and dead spaces are sharply contrasted.

Dead spaces are found in tissues which have been bruised and cut off from their blood-supply. We encounter them again in sloughs, in bone sequestra, and in the texture of cloth and intrusive foreign bodies. And we have a dead space in every abscess sac, and also in every other collection of pus, whether it lies open in the pocket of a wound or is confined under a slough or scab. The essential characteristics of dead spaces are two. First, they cannot be effectively searched by leucocytes. In some cases chemical, in others mechanical, conditions stand in the way. Secondly, the leucocytes which are engaged cannot be reinforced, nor can the fluid be renewed. Isolation from the circulation makes this impossible.

Let me try to tell you in the fewest possible words what this imports in infection. If in an infected live space the scale turns in favour of the microbes, there is still a chance of the balance being redressed. Reinforcements can at any rate be brought up. In infected dead spaces—and let me here point out to you that all the experiments we conduct in test-tubes are equivalent to experiments conducted in dead spaces—an advantage gained by the microbes becomes at once irretrievable. That follows from the impossibility of reinforcement.

Let me also tell you what happens to the patient when infection goes ahead in a dead space. In the first place bacterial poisons will be absorbed, and the patient will suffer from septic fever. In the next place the microbic infection—this will generally be a streptococcic infection, but in war wounds it may be a gangrene-bacillus infection—will very often invade the surrounding tissues and from thence the blood-stream. And in the third place, the pus in the dead space will, when it becomes tryptic, eat its way into the enclosing tissues. The abscess sac will then extend in all dimensions, or else the pus will burrow in the direction of least resistance until it opens upon an inner or an outer surface.

TREATMENT OF WOUND INFECTIONS.



If you have now quite clearly apprehended the significant distinction between a live space and a dead space, you will with that have mastered the first great principle governing the treatment of all local bacterial infections. If you are dealing with infection in live spaces you can often mend matters by bringing (that is the rationale of hot fomentations) more blood—that means more lymph and more leucocytes to the focus of infection; and again you can often mend matters by improving the quality of the lymph—that is the rationale of vaccine therapy; or, again, you may apply both these procedures concurrently. But when you are dealing with an infected dead space you cannot in these ways mend matters. You might just as well try to influence a test-tubeful of infected fluid. Where you have infected dead spaces, your only remedy is the knife. You have to evacuate your dead space as I empty this test-tube.

Now that is the whole purpose and meaning of the surgery of the wound as carried out at the front. We can compress that into two propositions. Every infected dead space must be cut down upon and evacuated. And, as a prophylactic measure, every space which would, if left to itself, become an infected dead space—that means every space occupied by an infected projectile or pieces of infected clothing or infected foreign bodies or devitalised infected tissues—must be similarly laid open and cleaned out. That exhausts the treatment of buried infections.

But it is only the beginning of the treatment of the wound. There is still the surface infection. The situation you have to face is just the same as that produced by emptying an infected tube: you have got rid of the infected contents, you have left the infection on the walls.

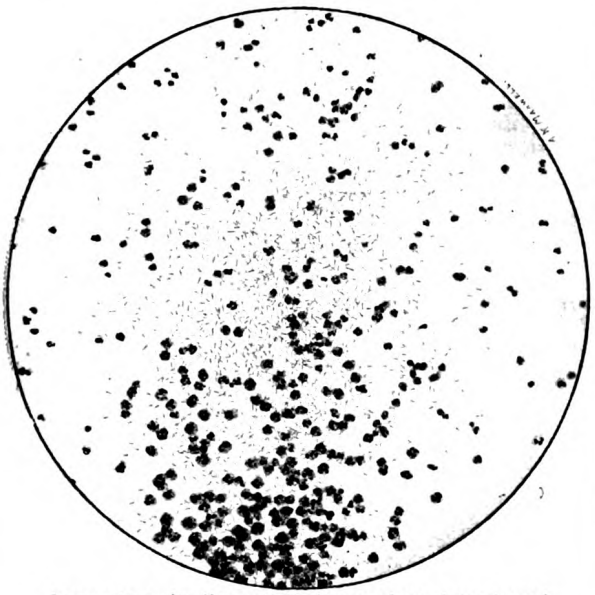
I now turn to the problem as to how best to deal with this infection. And here again inevitably we must establish distinctions. We must distinguish between the *naked tissue surface* made by the act of the projectile, or section with a knife, and the *granulating defensive surface*, which after a time clothes the naked tissues. In the former we have a non-vascularised surface, and in this a system of lymph spaces left without mechanical or biological protection other than that furnished by the emigration of leucocytes and (till that stanches) by the outflow of lymph. And the naked tissue surface is not only ill defended against microbic attack, it is also peculiarly liable to damage and to physiological deterioration of the kind which opens

FIG. 7.

Leucocytic emigration restrained by excess of streptococcic infection.

the door wider to such attack. Such a surface readily dries up; and drying means the closing down of the capillary circulation. Again, seeing that it is non-vascularised, a naked tissue surface will readily take cold, and by that both lymph outflow and emigration are arrested. And lastly, a naked tissue surface, if kept wet, will as soon as the discharges become tryptic, readily undergo erosive digestion. Against all these forms of physiological degeneration we should in our treatment of naked surface infections make special provision.

A granulating surface offers much greater protection against microbic infection, and is much less subject to damage. The tissues are covered in by many layers of protective cells, the lymph spaces are sealed over, and there has



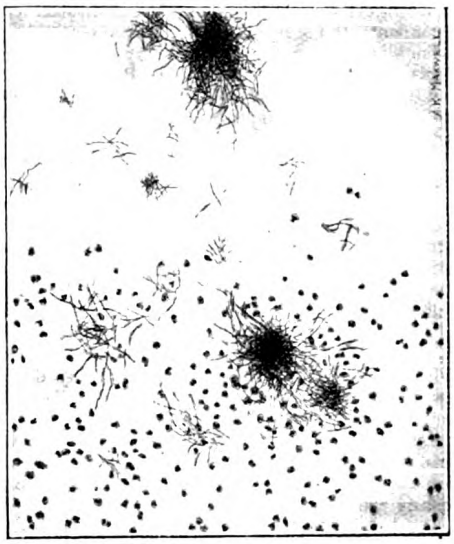
been laid down immediately below the surface in newly formed vessels a very abundant blood supply. All this gives sensible security against massive microbic invasion from the surface; against the wound taking cold; and against erosive digestion. In short, the treatment of the infected granulating surface will be less precarious than that of the infected naked tissue surface.

The Natural History of the Wound with a Naked Tissue Surface Left to Itself.

Let me first consider the natural history of the untreated wound with an infected naked tissue surface. I will take the case of an open shell wound left without treatment. According as it is wet or dry the evolution of this wound will be entirely different. Let us take first the case of its being allowed to dry. Under the original dry dressing the blood and lymph flow from the surface will gradually stanch, and we shall then have a naked tissue surface covered with a coagulated coating of blood and lymph. In this will be incorporated when the tissues have been bruised lacerated elements of moribund tissue, and there will be also included other elements of foreign matter and always a certain number of microbes. Little by little the coating of coagulated blood and lymph upon the surface of the original wound, or, as the case may be, of the surgeon's incisions, will dry up, and the capillary circulation underneath will gradually be closed down by desiccation. And all the while the serophytic microbes will be proliferating. As a result of all this the superficial tissues will die, and become gangrenous, and the originally clean naked tissue-surface will gradually be transformed into a dry, greenish-black, excessively fœtid, slough-covered surface pullulating with microbic growth.[2] Under the sloughs will then be formed infected dead spaces, and from these the infection—I am here thinking in particular of a gangrene infection—will invade the neighbouring live spaces, converting these in their turn into dead spaces until we have large areas of gangrene and a general intoxication.

That, of course, will happen only with very heavy infection or extreme physiological deterioration. With lighter

FIG. 8.



Leucocytes emigrating and attacking a colony of streptococci.

infection or less adverse physiological conditions in the wound, the invaded organism will have recourse to measures of defence. Gradually the superficial sloughs and gangrenous portions of the deeper tissues will be demarcated and then amputated from the living tissues—the amputating agent being, no doubt, the tryptic ferment in the dead spaces. And at the same time there will have been organised in the living tissues some little way back a defensive front built up upon the same plan as a granulating surface.

[2] Let us note in connexion with this microbic growth and fœtor that the albuminous substances of our tissues which, so long as they are bathed in lymph, rank as protected albumens, are, when the lymph stream dries up, degraded to the rank of unprotected native albumens.

Let me now tell you also what would happen if the infected surface is simply kept wet. Here, also, the microbes which have been incorporated in the clot would grow out. Then there would supervene leucocytic emigration, and upon that would follow a breaking-down of the leucocytes with a setting free of trypsin; and after that any and every microbe would pullulate in the cavity of the

FIG. 9.

Leucocytes emigrating and attacking colonies of the gas gangrene bacillus.

wound and in the devitalised tissues adhering to the surface. Finally, if treatment were still deferred there would be reproduced in an aggravated form (for there would in the open wound be a varied and more formidable infection) the evil train of events which is associated with infection in a buried dead space. When you reflect that an open wound cavity filled out with tryptic pus is physiologically equivalent to an unopened abscess sac, you will see that the same erosive action would be exerted upon its walls; that erosive digestion would enlarge and deepen its cavity; that these degenerative changes would enable the microbic infection to burrow everywhere deeper into the walls; and that bacterial poisons will be absorbed.

All I have been saying in the last few minutes can be compressed into this: an infected naked tissue surface becomes, if allowed to dry, *a desiccated slough-covered wound;* if simply kept wet, *a tryptic suppurating wound.* And the bacteriological events also can be put quite simply. A comparatively light infection, such as we have in the man whose wounds have been properly opened up and mechanically cleaned, is converted by transport into a very heavy infection; and a purely surface infection into an infection invading the deeper tissues.

PROBLEM OF PREVENTING THE DEGENERATION OF THE WOUND WHEN TREATMENT IS INTERRUPTED DURING TRANSPORT.

Having realised what happens to the wound when untreated, we have to think out how to keep wounds—whether originally completely open or opened by a surgeon—from falling during protracted journeys from hospital to hospital into these desperately unwholesome conditions. We have also to consider how to restore, as rapidly as possible, to their original wholesome state wounds which had lapsed into distressing conditions either through lying out untreated on the field or through interruption of treatment during lengthy transport.

Suggestion that the wound could be sterilised at the outset, and could be kept sterile by leaving an antiseptic in the wound.—The first thought of every man would probably be that the wound should be most carefully disinfected at the outset. But what happens in burns shows that to start in the case of an open wound with a sterile surface avails nothing. A burn is a form of wound which is at the outset absolutely sterile, and quite notoriously

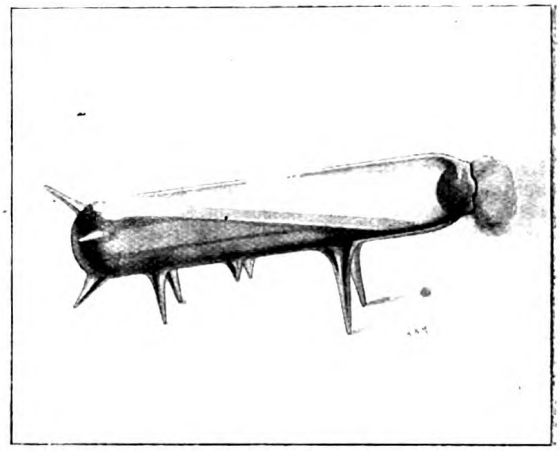
it tends to become very rapidly intractably septic. No doubt the germs begin to arrive before the burnt surface has well cooled off, and the wound is very rapidly peopled by microbes. Without doubt this is due to the emigrating leucocytes being held back in the superficial sloughs, disintegrating there and corrupting the exuding lymph. And this is not preventable by any application of antiseptics. The same holds true of war wounds. These become heavily infected even when the wounds are drenched at the outset with the strongest antiseptics, such as undiluted carbolic acid and concentrated solutions of iodine.

This is not the place for any lengthy discussion of the reasons for this failure of antiseptics. But the gist of the matter can be put quite shortly. The real truth is that the current belief in the therapeutic efficacy of antiseptics rests on experiments which are quite fallacious. They are fallacious in that the antiseptic in those experiments was applied in watery media—media which left that antiseptic unaffected. To have value—that is, to have application to conditions obtaining *in vivo*—the experiments should have been conducted in pus or serum—media which quench antiseptic action. Again, in the experiments of the past the antiseptics were intimately mixed with the bacteria suspensions; whereas, applied in the wound the antiseptic comes only into external contact with the infected wall, and when left behind in the empty cavity only into external contact with the inflowing discharges. Employed thus we cannot expect it to diffuse into and exert a bactericidal effect in either infected tissue or pus or serum.

By reason of the fact that these considerations were in the older experiments disregarded, the issue as to whether antiseptics applied in the wound with prophylactic intent can be of any use must be investigated quite anew.

Experimental Investigation of the Efficacy of Antiseptics.

Let me now try to indicate to you what sort of experiments should be undertaken by anyone before nourishing in connexion with a particular antiseptic the expectation that it is going to be efficacious for sterilising and afterwards suppressing microbic growth in wounds. I can illustrate my points best if you let me show you here four tubes.



In *Tube No. 1* I have a suspension of microbes in water. I now add an equal volume of the antiseptic I wish to test and shake up thoroughly. These are, as you see, conditions which give every possible advantage to the antiseptic. It is applied in a non-albuminous medium and is intimately mixed with the microbes. To find out whether the microbes have been killed I draw off a sample and dilute with very many times its volume of nutrient medium. I then incubate to see whether I get any bacterial growth.

In *Tube 2* I make the conditions more favourable to the survival of the microbes—infinitely more favourable than if I left behind an antiseptic in a wound. I have here a mixture of staphylococci, streptococci, and gas-gangrene bacilli suspended in serum, and I now, as in Tube 1, add an equal bulk of the antiseptic and shake up, and I then, following the technique of Professor Beattie, pour on a little hot vaseline which will afterwards congeal. This, by forming an air-tight seal, will allow the gangrene bacillus, if it survives, to grow out. It will also by its congealment confine the gas which this microbe evolves, and so will announce its growth.

Tube 3 is, as you see (Fig. 10), a tube which has been drawn out into a number of hollow spikes to imitate the diverticula of the wound. My colleague, Dr. Alexander Fleming, who devised it, calls it the "artificial war wound." To imitate the conditions obtaining in the actual war wound we fill both the tube and its diverticula with an infected trypsinised serum. We now empty the tube, leaving behind of necessity in the diverticula a certain amount of the original infected fluid. We then fill with an antiseptic; and the future of the infection will now depend on the penetrating power of the antiseptic. If the antiseptic penetrates into the infected fluid sterilisation will be obtained; if it fails to penetrate the artificial wound will remain infected. To find out what has happened we empty out the antiseptic, fill in with trypsinised serum, and incubate.

After asking in Tube 3 whether the antiseptic can completely sterilise a wound which has its recesses filled with an infected albuminous fluid, I go on in Tube 4 to investigate the question as to how far the antiseptic can penetrate into the walls of the wound. *Tube 4* is, as you see, a tube with hollow spikes. I have coated it inside with infected serum agar, and the hollow spikes give a greater depth of infected lining and also a better hold for that lining. As soon as the agar has solidified the infected tube is filled with antiseptic. And then we can, after an interval, pour out the antiseptic, fill in with nutrient broth or trypsinised serum, and then incubate. Any microbes which have been left alive in the lining will now grow out into colonies, and be visible through the walls of the tube.

FIG. 10.

A test-tube standing on spike legs, representing a war wound with diverticula.

Let me show you a set of typical results obtained by the procedures I have just described, using the antiseptic of Dakin, which is to-day perhaps the most popular of all antiseptics.

In Tube 1 we have obtained, as you can see by these subcultures, complete sterilisation. And it was obtained after only momentary contact with the antiseptic. In Tube 2, where a lightly infected serum was shaken up with an equal bulk of the antiseptic and then incubated with it, we have in this mixture of serum and antiseptic a very vigorous growth of microbes. You see the medium has become turbid, and there has been an evolution of gas which has pushed up the plug of congealed vaseline. In Tube 3—and here the antiseptic stood for four hours in the barrel of the tube—we have in that barrel a teeming multitude of microbes. And in Tube 4, after four hours' contact with the antiseptic, only that very thin layer of the infected lining which coats the barrel has been completely sterilised, and in the concavity of every spike one can see that the bacterial colonies have in the depth come up quite thickly, and that it is only in the very surface layer that the microbes have been killed. And I here show you in a parallel tube which has been incubated 24 hours longer that the microbes you have seen growing in the deeper layers very soon penetrate the sterilised superficial layer, and invade the fluid contained in the barrel of the tube.

When we find an antiseptic giving results quite different from those I have here shown you it will then, for the first time, become a rational policy to use an antiseptic at the front and to leave it in the wound with a view to safeguarding the patient during lengthy transport.

Suggestion that the bacterial infection in the wound can be kept down during transport by frequent re-applications of an antiseptic.—In the earlier period of the war the only method of re-applying an antiseptic was that of taking down the dressing, syringing the wound, and completely re-dressing. That was, especially in the case of deep wounds and compound fractures, a very lengthy and painful procedure, and one which was nearly impracticable in transport. For that complete re-dressing there has now been substituted by Carrel a procedure for washing and refreshing the surface of the wound through rubber tubes. According to Carrel, Dakin's antiseptic should be employed and this should be applied every two hours. Let me about the application of this in transport say this: that it would, I think, be impracticable to carry it out on a sufficiently

large scale and sufficiently systematically; and treatment with Dakin's antiseptic applied in an unsystematic manner gives exactly the same results as simply keeping the wound wet.

Suggestion that the set-back in the wound during transport could be prevented by dressing with hypertonic salt solution.—The set-back in the wound with its resulting tragedies could, I think, be avoided by drawing out lymph in a continuous manner from the tissues, and by holding up at the same time the emigration of leucocytes. By the outflow of lymph we should be driving back and expelling invading microbes. We should also thereby be preventing the conditions in the walls of the wound becoming unwholesome to leucocytes. We should further, by the continuous outpouring of lymph, be effectively combating the corruption of the discharges in the cavity of the wound. And lastly we should, at the same time, be preventing any drying up of the wound. By holding up the emigration of leucocytes we should (you will remember that leucocytes will when they break down, furnish trypsin) be taking steps to prevent the corruption of the wound discharges.

We have in a hypertonic solution the therapeutic agent we require for these purposes. The proper way of using it is to apply to the wound three or four layers of lint thoroughly soaked in 5 per cent. salt solution; to impose upon these, as a reinforcement, three or four more layers of lint thoroughly soaked in a saturated salt solution and then cover the whole with jaconet, or other impermeable material.

REMEDIAL TREATMENT.

I now pass from discussion of the method of preventing the set-back that occurs in transport to the discussion of remedial treatment. The set-back will, as we have seen, have given us either a tryptic suppurating wound or a dry slough-covered wound. In each case the *first item in treatment* will be to get a clean surface. For that it will, in the case of the tryptic suppurating wound, suffice to wash away the tryptic pus. In the case of the desiccated slough-covered wound we must get rid of the sloughs. The rational way to do that will be by *cleansing digestion*. Such cleansing digestion can be obtained by treating the wound with hypertonic salt solution. This will, as we have already seen, break down leucocytes, setting free trypsin, and then the free trypsin will rapidly, and especially rapidly if we let the hypertonic salt undergo dilution, amputate the dead from the living tissues. Let us note that what we set out to do by the use of hypertonic salt solution is only to achieve more rapidly, and, as we shall see, with less risk of infection, what putrefaction and the destruction of leucocytes by microbes would, if we allowed things to run their course, spontaneously effect. The *second item* of treatment in each case will be to combat the infection which has found a lodgment in the lymph spaces in walls of the wound cavity. To deal with this we require to wash out by an outpouring lymph stream, and this, as I pointed out a moment ago, is obtainable by treatment with reinforced hypertonic salt solution.

If the train of reasoning I have laid before you is correct, it will follow that hypertonic salt solution is the agent we require both for preventing the set-back due to interruption of treatment in transport, and also for remedial treatment.

EXPERIMENTS WHICH EXHIBIT THE PROPERTIES OF HYPERTONIC SALT SOLUTION.

You will very reasonably here expect me to produce experiments to show that a hypertonic salt solution has the virtues I ascribe to it. You will want to see for yourselves that it attracts water and can draw out fluid from moist tissues; and that it can set free trypsin from pus, and initiate digestion.

Drawing Action of Strong Salt Solution.

I have here (*a*) two cylinders of agar containing salt to saturation and (*b*) two cylinders of water agar—all cast to the same size in 100 c.c. measures, and all rendered insoluble by an addition of formalin. Let us take first the cylinders of water agar. Upon the one of these as it stood in the measure was imposed a little saturated salt solution, solid salt being afterwards supplied as required. You see that the salt has here drawn out water copiously. The agar has everywhere detached itself from the walls, and we have in the interspace and on the top of the cylinder some 40 to 50 c.c. of fluid. The control cylinder of water agar which has been exposed to the air has, as you see, not shrunk at all.

Exactly the converse has happened with the cylinders of salt agar. These were taken out of their moulds: one was put down to steep in water—that one has, as you see, swollen to twice its bulk; the other was immersed in saturated salt solution—that one has not altered in bulk. We thus see that salt attracts to itself water. It can, according to the conditions, draw it out from or into a moist menstruum.

I have here in these three test-tubes another form of moist menstruum—cotton-wool impregnated with egg-albumen. The plug—in each case a very tight plug—is, as you see, placed half way down the tube, dividing it into an upper and lower compartment; and immediately below the plug I have a lateral hole (now sealed with plasticine).[3] Through this hole I can wash out both compartments very thoroughly, and fill and empty them without disturbing the plug. I have used in these experiments three fluids: a diluted egg-albumen with a specific gravity of 1026 for my plug, and two extracting fluids—water, and a saline solution containing about 8 per cent. of common salt with a specific gravity of 1052. In *Tube 1* I have water above and below; in *Tube 2* salt solution above and below; and in *Tube 3* water above and salt solution below. And here are the results obtained 24 hours after by emptying out the fluids and boiling them *secundum artem*. In *Tube 1* we have in the fluid from the upper compartment a mere trace of albumen; in that from the lower a very massive floccular deposit. That means that in the lower compartment the heavier albuminous fluid has sunk to the bottom, and in the upper only a mere trace has diffused upwards against gravity. In *Tube 2*, where both compartments were filled with salt solution, we have in the upper a massive floccular deposit, and in the lower a heavy but not nearly as heavy a one. It is the result in the lower compartment which specially interests us. It shows that an albuminous fluid is drawn down into salt solution in opposition to gravity. In the upper compartment, superadded to the drawing action of the salt, we have a displacement upwards of a lighter by a heavier fluid. In *Tube 3* (see Fig. 11), with water above and salt solution below, the upper compartment contains, as in Tube 1, only a mere trace of albumen. In the lower compartment we have again, as in Tube 2, a very heavy deposit of albumen drawn down against gravity.

I have here other experiments of which I show you photographed drawings. All these bring out that when strong salt solution and water are brought into apposition, and we introduce such a succession of obstacles as are provided by a cotton-wool plug or a wick, we get, so far as the convection of fluids is concerned, the same results as with a thin membrane, such as parchment paper or a film of formalin gelatine. But with respect to the character of the fluid we get a different result. When we employ only very minute pores we filter out albuminous substances; where we employ macroscopic pores albuminous substances are carried through.

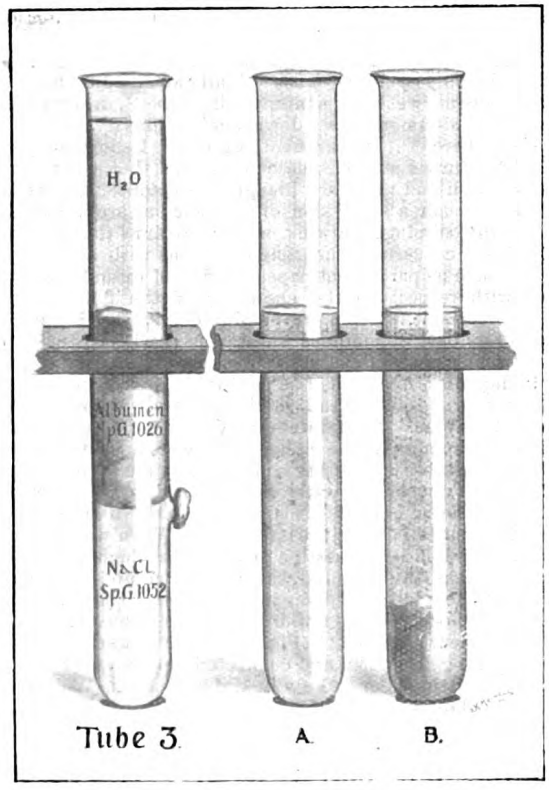
In my next experiment (Fig. 12) we have in one beaker saturated salt solution and in the other water coloured with methylene blue. To maintain the fluids at the same level we connect them up with a siphon filled with uncoloured water. We then establish a further connexion by means of a siphon filled with uncoloured water and blocked by a cotton-wool plug at the one end. This end goes down into the salt solution, but it is only just immersed. When we now watch events—and it is a question of watching them for weeks—we find that the coloured water is drawn up into the open limb of the plugged siphon in the manner shown. In the case of the open siphon nothing of this sort occurs.

In the next experiment (Fig. 13) we have a series of three tubes arranged tandem and connected up by wicks of moist bandage fitting very loosely in siphon tubes. We have in Tube A plain uncoloured water, in Tube B water coloured with methylene blue, and in Tube C saturated salt solution—all these being filled in to exactly the same height, and then protected against evaporation. We now observe that the level of the fluid in C gradually rises, while that in A and B sinks; and at the same time the colouring matter from B is gradually conveyed up the wick in the direction of C, but is not carried up in the direction of A.

In the next experiment (Fig. 14) we have again a series of three tubes arranged tandem and connected up by wicks as in the last experiment. In A we have plain water, in B an albuminous fluid, and in C saturated salt solution—all filled in to exactly the same height. As in the last experiment, the level of the fluid rises slowly in C and sinks away

[3] In sealing with the plasticine care must be taken not to produce a positive pressure, and so drive albumen up into the upper compartment.

in A and B. We then unship Tubes A and C, add salt to A, and then boil both. We find that a great deal of albumen has been carried over into C, and that none has diffused over into A.



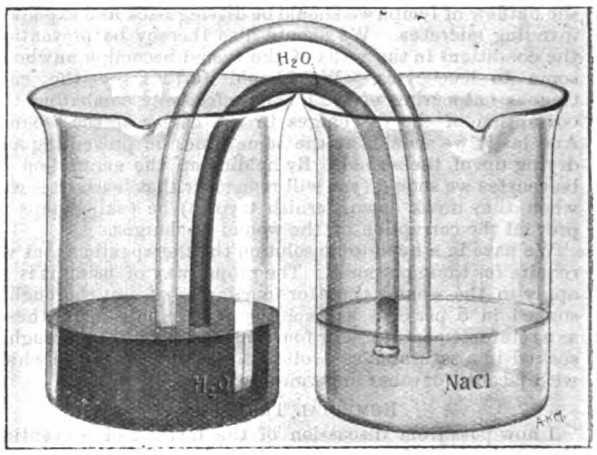
The Setting Free of Trypsin by Hypertonic Salt Solution.

You will probably not want to see any further experiments on this point. But I have still to make good to you that a hypertonic salt solution sets free trypsin from pus and initiates digestion. On that matter I will content myself with showing you the two following experiments.

Experiment 1.—I have here, as you see, two test-tubes filled nearly to the top with egg-albumen. To this was added ½ per cent. of carbolic acid, and the albumen was then solidified by immersing the tubes in boiling water. That done I took two cotton-wool plugs and steeped them in a pus to which I had added again ½ per cent. carbolic acid. I then inverted my tubes, the one into a beaker containing 5 per cent. salt, the other into a beaker containing physiological salt solution. (Fig. 15, A and B.) To these also I added ½ per cent. of carbolic acid. You will understand why I chose carbolic acid as my antiseptic when I tell you that it is an antiseptic which does not destroy trypsin or impede digestion. You see in the drawings made after the tube had been incubated for 48 hours, that in Tube A, the tube which was immersed in hypertonic salt solution, the egg-albumen was extensively digested, while in Tube B there was only a mere trace of digestion.

Experiment 2.—I here try to imitate the conditions of slough-covered wounds. I have in these beakers a foundation of coagulated white of egg containing 0·5 per cent. of carbolic acid. On the top of this I have in each case a

FIG. 11.



Tube 3 is flanked with test-tubes labelled A and B showing the result of boiling the fluid from the upper (A) and the lower (B) compartments of this tube.

disc of lint, woolly side up, firmly fastened down by adding another layer of egg-albumen and coagulating this by heat. Upon the lint I have poured a non-tryptic pus, giving, of course, an equal amount to each beaker. In this way I have made what I think can pass as representing fairly closely pus-impregnated sloughs in wounds firmly adherent to the tissues beneath. (Fig. 16, A and B.)

We now pour upon one of the artificial sloughs 5 per cent. and upon another 0·85 per cent. solution made up with ½ per cent. carbolic acid, and we may pour upon a third Dakin's solution. And we now place them all in the incubator. You see here what has happened after 24 hours. In *Beaker A*, where the artificial slough has been treated with

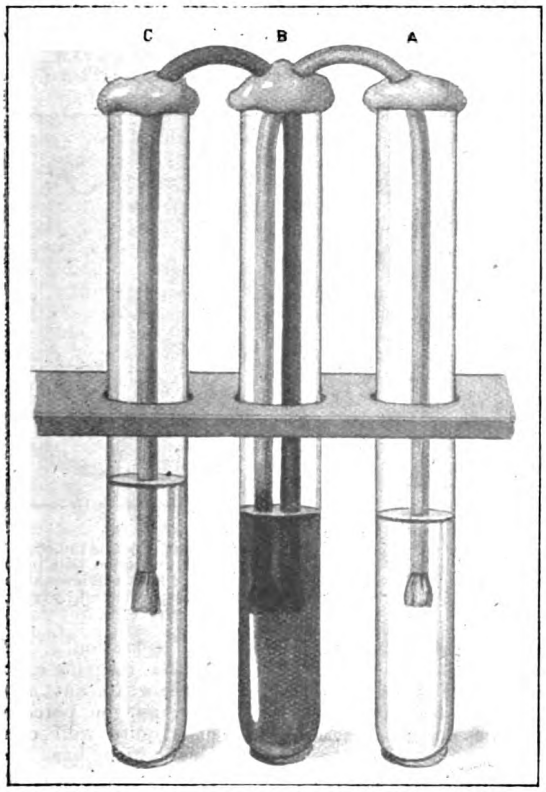
FIG. 12.

The left-hand beaker contains water coloured with methylene-blue; the right-hand beaker strong salt solution. The beakers are connected up by two siphon U tubes—the upper being an open siphon filled with uncoloured water; the lower a siphon plugged with cotton-wool and like the upper siphon, filled in at the outset with uncoloured water.

hypertonic salt solution, the slough has loosened itself from its bed, and floats up as I pour in water. In *Beaker B*, where I imposed only physiological salt solution, the slough is still firmly adherent. And the same holds of *Beaker C* (not figured), where we have Dakin's solution.

We have here, as you see, an instructive experiment. And we can derive from it more instruction than has as yet appeared. In the first place, if we carry the experiment further, the slough which has been treated with physiological salt solution will also separate. In contrast with this will be what will happen with the artificial slough treated with Dakin's solution. Here, especially if the Dakin's solution is periodically renewed, the clot will remain adherent. For the Dakin's solution, while it is destructive to leucocytes, is when not quenched by albumen destructive also to the trypsin which brings about the separation of the slough.

We can always appreciate the situation and tell what is going to happen whether in the wound or *in vitro* by taking samples of the fluid and testing quantitatively for trypsin with milk containing about ½ per cent. of calcium chloride cryst., and we can when making experiments *in vitro* on the separation of artificial sloughs, hurry up the events by conducting the digestions at 50° C.



We can also vary our experiment with weak and strong salt solution by leaving out the antiseptic. Then microbic growth will, more particularly in the weaker salt solution, proceed unchecked, and the destruction of leucocytes by that growth will play an important rôle in the loosening of the clot. Meanwhile, the microbes will be everywhere making their way deeply into the albuminous substratum. This imitates what is occurring in every untreated slough-covered wound. While on the surface sloughs are decomposing and separating, in the depth further tissue is becoming heavily infected and gangrenous. In treatment we must combat that inward extension of the infection, and since we cannot block the infection by antiseptics, we must place mechanical and biological obstacles in its path. That means we must get lymph to pour out in full stream from the deeper tissues, and, if we achieve this, we may, after the sloughs have separated, look to have a clean, comparatively lightly infected wound surface.

TREATMENT OF THE WOUND IN THE CASE WHERE WE HAVE ONLY A LIGHT SURFACE INFECTION.

When we have got back to a clean and only lightly infected surface we must think out our next step in treatment.

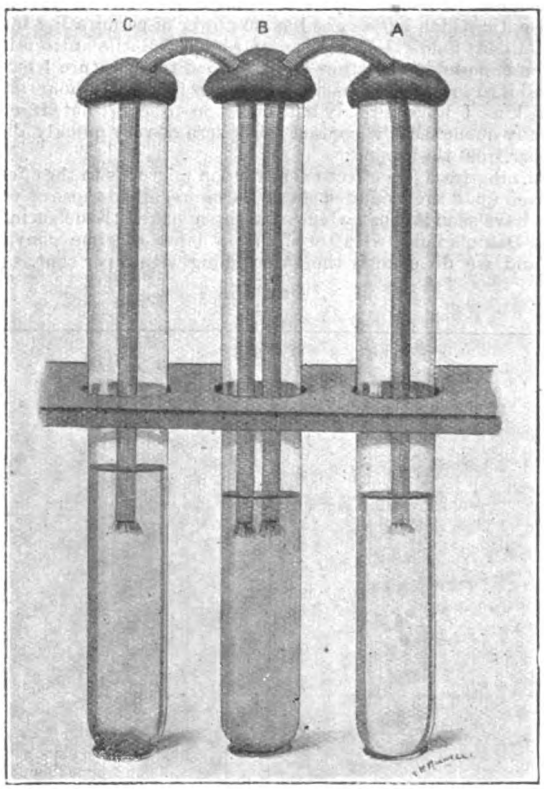
It will help if we first review what we have learned by the way so as to see the whole history of the wound in perspective.

FIG. 13.

Tube A contains uncoloured water; Tube B, water coloured with methylene blue; and Tube C, saturated salt solution. The fluids stood originally at the same height in each tube.

We have learned that there are in wound infections two supreme dangers. *First*, there is the danger associated with the buried infection. We have appreciated that the effective and only remedy for this is the immediate opening up of the infected dead spaces, and you will remember that is a question of converting a buried infection into an open surface infection. The *second* very serious danger is that intensification of the surface infection which follows upon a lengthy interruption of treatment during transport. This, regarded from the point of view of loss of life and limb, ranks next in order of importance after delay in dealing with the buried infection. When the set-back due to transport has been prevented or remedied, we have confronting us the problem which, if treatment had been uninterrupted, would have presented itself earlier—the problem as to how to treat a slight infection of a naked tissue surface.

One of the ways of treating this is to leave the wound to heal up from the bottom, limiting oneself to such re-dressing as would prevent erosive digestion. By this programme the patient would, when his wound is a large one, be condemned to very many months of disability and also of bacterial intoxication. For the fact has got to be faced that it is all but impossible to maintain satisfactory conditions in a large wound for months on end.



The alternative programme is for the surgeon to close the wound with the minimum delay. If the anatomical conditions permit, and the bacteriological examination shows the wound surface to be practically uninfected, or if the wound is only a very few hours old and the implanted microbes cannot yet have grown out, the wound can, after removal of all dead and foreign matter, be immediately closed—the surgeon, of course, standing by to reopen the wound if symptoms of buried infection develop. If, on the other hand, bacteriological examination shows that the wound surface is appreciably infected, or the history of the case makes this practically certain, then we should, by closing the wound, be violating all the principles of surgery. For we should simply be converting a surface infection into a buried infection. The proper step to take with a wound which is appreciably infected is to reduce the microbic infection to the point at which it is negligible and then re-suture.

Methods of Dealing with the Microbic Infection.

The microbic infection may be dealt with by any one of the following procedures.

In the *first place* we can employ the physiological procedure. If we elect to do this, we must think out clearly the physiological problem. For example, it will be inappropriate when dealing with a purely superficial streptococcic and staphylococcic infection to continue the application of hypertonic salt solution. The effect of that would be, on the one hand, to hold off phagocytes from the microbes (for strong salt arrests emigration); and, on the other hand, to provide the staphylococcus and streptococcus with lymph, a fluid in which they can grow and disseminate themselves over the whole face of the wound. What we want is an application which calls out leucocytes, and which will restrain, or which at any rate will not activate, the lymph flow. Physiological salt solution, and zinc sulphate in ¼ per cent. solution, and no doubt many other heavy metal salts in dilute solution, are the sort of agents we require. But what is, above all, essential to success in physiological treatment of a surface infection is to be very assiduous in removing any leucocytes which may break down upon the face of the wound. That is a question of maintaining intact the antitryptic power of the discharges.

FIG. 14.

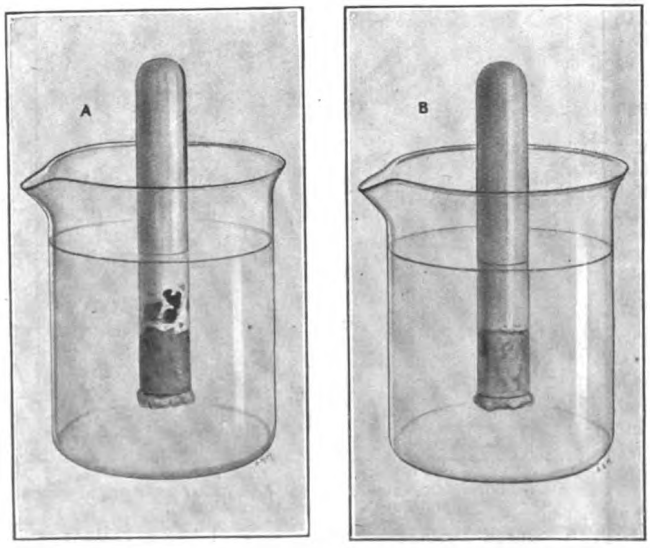
Tube A contains plain water. Tube B a watery solution of egg-albumen and Tube C saturated salt solution.

A *second method* of procedure—I may call it the *unreasoning antiseptic procedure*—is to employ an antiseptic, considering in connexion with it only the fact that it is called an antiseptic. That means using an antiseptic without laying stress upon the assiduous cleansing of the wound surface and the maintenance of good physiological conditions; without inquiring whether the antiseptic can, when brought into external contact with pus or an infected tissue, penetrate into it; and without asking whether the antiseptic hinders phagocytosis, or destroys the antitryptic power of the blood fluids, or permits or interferes with tryptic action.

This unreasoning antiseptic procedure is constantly employed. It has led to failure upon failure, and it would be a matter for wonder if it did succeed.

The *third* and last method of procedure I may call the *combined antiseptic and physiological procedure*. If we want to find a method of this sort we shall not find it by inquiring for it under this name. What we have to seek is a method which proclaims itself an antiseptic method and which in this guise combats effectively, but perhaps not with full comprehension, corruptive changes in the wound.

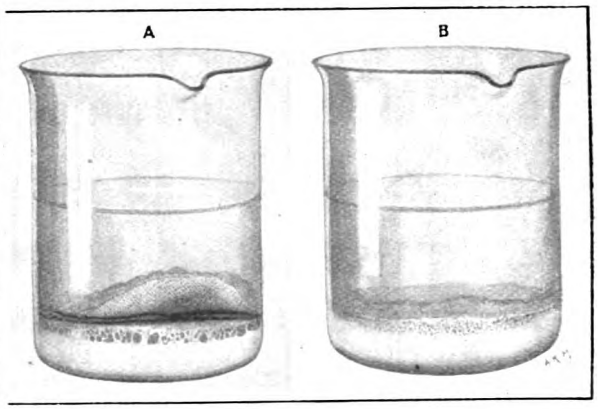
The method of Carrel is, as I think, such a method. I would propose to make good that it is a combined antiseptic and physiological method; then to survey the results obtained; and finally to consider how to determine how far the results should be credited to the antiseptic, and how far to the physiological, element in the treatment.



We have in Carrel's treatment two factors: (*a*) Dakin's antiseptic, or, as I should prefer to call it, Dakin's therapeutic agent; and (*b*) Carrel's procedure for washing and refreshing the wound surface in the intervals between the complete dressings. Now each of these factors, quite irrespectively of what it does in killing or removing the microbes, makes the conditions in the wound unfavourable for microbial growth. Let me, taking first Dakin's fluid, and then Carrel's washing procedure, try to make for you an inventory of their directly anti-bacterial, and their physiological or indirectly antibacterial, effects.

Dakin's Fluid.

Dakin's fluid is, as I have shown you,[4] a very ineffective antiseptic when it is brought into application upon microbes suspended in serum. It is also, as I have shown you, an antiseptic which has as good as no power of penetrating into albuminous fluids. It is also an extremely volatile antiseptic. When exposed in a shallow dish at blood temperature I have found it to lose four-fifths of its potency in half-an-hour, and it will, as I have already had occasion to point out, if not already quenched by contact with serum, very quickly disappear from the wound.



Turning from the effect exerted upon microbes to the effect exerted upon the wound surface, let me recall to those of you who have seen it, that when we treat a naked tissue surface with Dakin's fluid, we after a certain lapse of time convert it (and we do exactly the same thing with 5 per cent. salt solution) into a bright coral-red granulating surface. That means we convert it into a defensive surface excellently well provided with new-formed blood-vessels from which active leucocytes and fully potent lymph will emerge. Leucocytes also are affected by Dakin's fluid. Experiments show that it is destructive to phagocytosis. When we add one part of the reagent to nine of *excoagular blood* we reduce the phagocytic power of that blood by more than one-half. We abolish phagocytosis when we add one part of the reagent to four of blood. The fluid elements of the discharge also are altered in character by Dakin's fluid. Let me remind you here that we saw in our experiments on artificial sloughs that treatment with Dakin's solution hinders the digestive processes which bring about their separation. This stands in relation to the fact that the reagent exerts upon trypsin, when albumen is not there to act as a buffer, a destructive action. We have, as you perceive, here a physiological action which may quite well come into operation when a wound surface which has been tryptic is flushed. But Dakin's fluid will act not only upon trypsin. It abolishes also the antitryptic power of the blood fluids. So, applied in the wound, it might perhaps with one hand give protection, and with the other hand take it away. But what really does happen is, I suppose, that all free trypsin is destroyed by the flush and that afterwards, when the hypochlorite is quenched or vaporised, new antitryptic lymph and with this new leucocytes emerge from the wound surface.

FIG. 15.

Test-tubes filled with coagulated egg-albumen; then plugged with cotton-wool impregnated with pus: and then inverted into beakers. Beaker A contains hypertonic, Beaker B normal salt solution.

FIG. 16.

Beakers containing coagulated egg-albumen into which is imbedded a layer of lint. Upon the lint was poured pus, and upon this in the case of Beaker A hypertonic, and in the case of Beaker B normal salt solution. In Beaker A the artificial slough has separated off by tryptic digestion.

And the particular train of thought here started is, perhaps, worth following up. We may, I think, profitably ask ourselves whether if put to our election between maintaining antiseptic action continuously at the expense of physiological action, and alternating antiseptic with physiological action, we should not do well to elect for the latter policy. And we may muse whether it was not specially felicitous to have employed, as Carrel has done, an antiseptic which is very readily quenched and also very volatile and to have applied it discontinuously. Had that antiseptic been employed by a method of continuous irrigation, phagocytosis on the face of the wound would have been excluded, and we should have had in the cavity of the wound a lymph whose antitryptic power had been destroyed.

But I have already said enough about Dakin's fluid if you have appreciated that it is a poor antiseptic; that it acts as a poison upon leucocytes and blood fluids; that its physiological action is a very complicated one; and that its beneficial effects cannot be due simply to its antiseptic action.

Carrel's Method.

I now come to Carrel's procedure of intercalating between the complete dressings a frequent flushing and refreshing of the wound surface and for carrying out this flushing unlaboriously. Allow me to say that we have here, I think, far the most important contribution made to surgical technique since the beginning of the war. But to that let

[4] Vide supra, Experiments on Antiseptics.

me add, that while Carrel's procedure gives us a new and improved technique for the application of antiseptics, much more does it give us a new and improved technique for physiological treatment. For that treatment the assiduous removal of corrupted and corruptible discharges is, as you know, the primary desideratum.

We now turn to the results of the treatment of infected wound surfaces by Carrel's method, and we may take them from Carrel's book. But it will be well, in order to keep to the kind of wound infection here under discussion, to exclude from consideration wounds complicated with fractures—for in those effective washing is difficult. Within our purview will then only lie wounds of soft parts, and in Carrel's book these are distributed under (*a*) fresh wounds—wounds taken in hand when 5 to 24 hours old; (*b*) phlegmonous and gangrenous wounds; and (*c*) suppurating wounds. The first of these categories would broadly correspond to wounds with a naked tissue surface lightly infected. The others would correspond to wounds which have, through postponement of treatment or its interruption by transport, suffered a set-back, converting an originally light surface infection into a heavy infection with invasion of the deeper tissues. Having now got your bearings, you will see that we have already, in discussing remedial treatment for the set-back, discussed the last two of Carrel's three classes of wounds. And we learn from the data he gives with respect to these only this—that the combined operation of treating the set-back and reducing the remaining light infection to a negligible infection permitting successful re-suture occupies by his method 3 to 4 weeks. This, of course, does not tell us how long it takes to convert a light surface infection into a negligible one. For that we must turn to the data relating to fresh wounds; and under that heading we find that where there are sloughs to be dealt with 15 to 20 days; and, where there are none, 5 to 12 days are required. That gives us a measure of what can be done by what I have, I hope not without good warranty, called Carrel's "combined antiseptic and physiological treatment."

Let us consider what Carrel's results tell us. They tell us in the first place that, whatever else it is, Carrel's treatment is not in any sense a *therapia magna sterilisans*. Regarded as an antiseptic method, it is a method of "*fractional sterilisation*" requiring for the case we are considering—the simplest case of all—at the rate of 12 douches a day a series of 60 to 144 antiseptic douches. And if I am right in regarding Carrel's treatment as a combined antiseptic and physiological treatment, we have, superadded to the antiseptic, a series of 60 to 144 physiological attacks upon the microbes—each such attack starting from an atryptic condition.

The consideration of these figures leads directly to what I have to say in conclusion. While Carrel's work constitutes a very notable practical achievement, regarded as science it comes short in the respect that adequate control experiments are lacking. I do not mean that it has not been demonstrated that Carrel's treatment accomplishes what was impossible by the old system of syringing with antiseptics and leaving the wound afterwards to fill with pus. The inefficacy of that older treatment was attested by tens and hundreds of thousands of control experiments. What I mean is, that we have not in Carrel's work any control experiments with more potent and penetrating antiseptics to negative the idea that with these one could with less than 60 to 144 consecutive douches convert a light surface infection into a negligible one. And again, we have not from Carrel any control experiments with a well-thought-out physiological treatment to negative the idea that one could achieve a similar sterilisation by 60 to 144 successive physiological attacks upon the microbes, starting each time from an atryptic condition.

If we would abide in the spirit of science, every unwarranted assumption must go. We must not assume that when we have successfully combated a surface infection by a series of 60 to 144 therapeutic operations we have reached finality. And much less must we, from the fact that a treatment successfully combats surface infections, infer that it is also an effective treatment for infections which penetrate into the deeper tissues. It ought to come home to us instead that we must never look to find for quite different categories of wound infections—i.e., for quite diverse conditions—any one routine (antiseptic or physiological) treatment.

MASKS FOR FACIAL WOUNDS.

BY FRANCIS DERWENT WOOD, A.R.A., R.S.B.S.,
LIEUTENANT, G.S., ATTACHED 3RD LONDON GENERAL HOSPITAL, R.A.M.C. (T.), WANDSWORTH, S.W.

IN describing the use of modelled masks for covering facial wounds I have to call attention at the outset to two important points: no attempt is made in any of my contrivances for the alleviation of the sufferings of the wounded, to restore functioning or to produce a cosmetic effect by plastic methods.

In certain cases the effects of impaired functioning may be alleviated to a greater or lesser extent, as, for instance, where the nerves affecting the salivary glands have been destroyed, or where the nerves of the eye have been so injured that the control of the tear-ducts is defective and a constant discharge is the result. In such cases I arrange for the attachment of an absorbent pad or pads within the mask which relieve the patients from considerable inconvenience.

Dr. A. Pont, the director of the Dental School of Lyons, in an article in the *British Dental Journal*, deals constructively with the question of nasal prosthesis, and incidentally remarks that "living restorations are indicated for cases of flattened noses, in certain cases of fracture, &c., but cannot enter into account where it is a question of replacing the nose totally or partially."

My work begins where the work of the surgeon is completed. When the surgeon has done all he can to restore functions, to heal wounds, to support fleshy tissues by bone-grafting, to cover areas by skin-grafting, I endeavour by means of the skill I happen to possess as a sculptor to make a man's face as near as possible to what it looked like before he was wounded. My cases are generally extreme cases that plastic surgery has, perforce, had to abandon; but, as in plastic surgery, the psychological effect is the same. The patient acquires his old self-respect, self-assurance, self-reliance, and, discarding his induced despondency, takes once more to a pride in his personal appearance. His presence is no longer a source of melancholy to himself nor of sadness to his relatives and friends.

As a general rule the cases that come to me are those in which the wounds or depredations of disease have been so severe as to remove them beyond the range of even the most advanced plastic surgical operations. So far as my treatment goes the size of the area affected is negligible. In theory it is as easy to make a mask for a whole face as for a space an inch square to cover a small palpitating area such as is often done in the case of skull wounds.

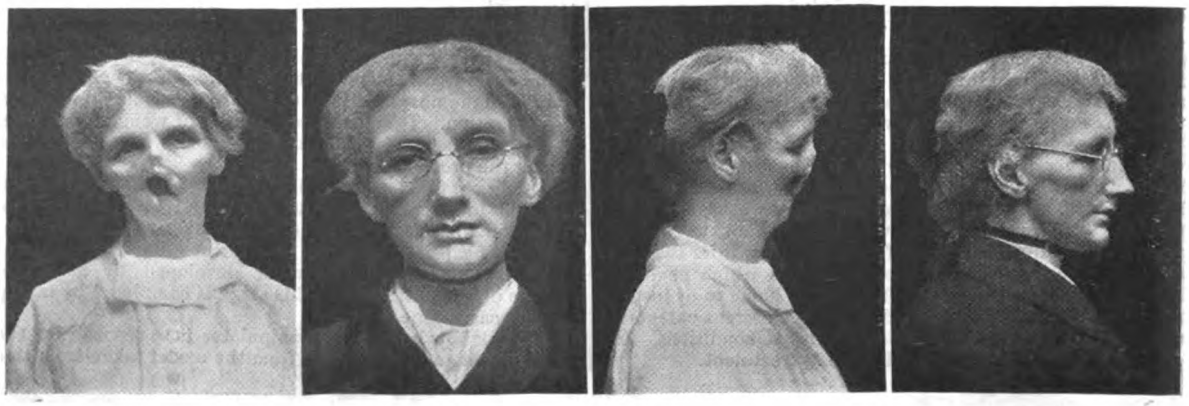
The essential of the treatment is the restoration of features; the features may have been originally ugly or beautiful. As they were in life so I try to reproduce them, beautiful or ugly; the one desideratum is to make them natural. Considerable experiment has proved that only a rigid mask can be depended upon, both for hygienic and cosmetic reasons. Various soft substances, such as gelatine mixtures, have been tried and have failed. Such applications cannot be either healthy or beautiful.

Description of Technique.

In order to approach as near as possible to nature, by my method a casting is made of the patient's face in plaster-of-Paris. This can only be done when the surgeon has discharged him as superficially clean and healed. This cast is essential, for a perfect edge-fit is required, so that adjustment is reduced to a minimum. All wound cavities are filled up with dressing and cotton-wool, and these in turn covered with goldbeater's skin. The nostrils are blocked with cotton-wool, the patient breathing through the mouth; if through the nose a quill is inserted for breathing throughout this operation. It depends on the area of wound, of course, as to whether nose or mouth breathing can be allowed during the process.

Having obtained the mould and dried it slowly the next stage is to French-chalk it and take from it a clay or plasticine squeeze, which provides a positive model of the patient's healed wound and the surrounding normal tissue surface. This model is further developed by means of sittings of the patient, and this stage is completed by taking another cast—a negative.

The task now before the manipulator is to reconstruct the destroyed feature or features from the model taken from this



CASE 1.—Artificial pinna.

CASE 2.—Replacement of lost parts by metallic nose.

CASE 3.—Showing artificial nose and cheek, artificial eye, and metallic eyelashes.

CASE 4.—Mask used in case of rodent ulcer.

negative mould, by building them up to match the corresponding or adjoining features of the patient, or from prewound photographs, taking the utmost care the whole time to keep the adjustment of the edges to the patient's face-planes. A cast is then taken of this; further manipulation is required for the fitting of an artificial eye (if the case includes such); a last comparison with the original is made, and the mask, in plaster, is complete.

From this an electrotype plate is deposited. It is of pure copper, 1/32 inch in thickness. The necessary fitments for glass eye and attachments are fixed, and it is finally well covered with an electric deposit of silver.

The last adjustments are now made to the patient's face, the securing of the plate to the face being carefully considered. The attachment is usually made by means of strong spectacles, but spirit-gum and ribbons have sometimes to be used, varying with the character of the wounded area.

The utmost care has to be made in fitting the attachments. I have received great help from Messrs. J. Hamblin, Ltd., the makers of the spectacles, who have devoted special care and attention to the work. Everything depends on the efficiency of the attachments in the matter of comfort to the patient, which is necessary in such cases, so that his attention shall never be drawn to his deficiency unless necessarily. The adjustment must be exact, therefore, and the edges of the plate can in no case be allowed to part from the sections of the patient's skin with which they coincide.

The plate has now to be pigmented to match the complexion of the patient. A thin coating of cream-coloured spirit enamel forms a good basis for the subsequent flesh-colour matching, as it leaves the oil-colour mat when dry, which facilitates the blending of plate with face. If the patient has an oily or shiny skin a semblance is easily obtained by varnish rubbed down to match. I do not use false hair for eyebrows and eyelashes now. The eyebrows are painted to match and the eyelashes I make of thin metallic foil, carefully soldered to the plate, cut finely by scissors, and tinted to match. I purchase the plain glass eye-sections and paint the eye-match on the concave reverse myself. Sometimes I do not use glass at all, but paint a semblance to match direct upon the metal mask, due preparation for this mode, of course, having been made in the plate.

The plate can now be worn and the patient finally discharged. Renewal of the pigmentation must be made from time to time, however, for scar tissue changes the contours of the face, and readjustments must occasionally be made. If these changes are very great a new plate might have to be substituted for the original, but in this only the same difficulties that were met with in the original stage would be encountered.

The Cases Dealt with.

My work has been done in close and constant coöperation with Lieutenant-Colonel Bruce Porter, C.M.G., R.A.M.C.(T.), and the medical staff of the 3rd London General Hospital at Wandsworth. It grew out of the establishment there of the splint room, of which I was in charge, and in which specific splints were prepared for exceptional wounds, and plaster casts taken of all such and kept to form the museum of cases there.

Sir Alfred Keogh, G.C.B., Director-General A.M.D., has directed the staffs of the various military hospitals to place all cases suitable for this treatment at the 3rd London General Hospital, and I am always glad to know of cases from those or other sources in order that all that is possible to be done for the facially disfigured shall be done.

It is obvious that if, in the cases hereafter described, plastic surgical operations could have brought about an endurable result, then such would have been preferable. To wear an artificial substitute for any feature must necessarily be always a burden added to the consciousness of the man or woman so sorely stricken. The fact remains, however, that through lack of time or accommodation in hospitals, or through plastic-surgical failures due to immense pressure of work, cases come out which only the hand of the sculptor can deal with, or hands trained to serve both plastic and sculptural manipulations, or a process combined of both.

In the cases of which particulars are given I have selected three of soldiers and one of a civilian, a woman. The latter I selected for the reason that the ravages of the disease were very extensive, and the surgical operation therefore comprised a considerable area of the lower half of the face, and, further, to note the fact that it is not only the wounded in battle or by accident that may take advantage of this remedial treatment, based on the skill (such as I and others may possess) and the knowledge of the sculptor. On these two things the success of the treatment entirely depends.

CASE 1.—*Injury:* Loss of right pinna by abrasion. The parts torn were so fragmentary as to be useless for a plastic operation. They were cut away, leaving the external orifice only exposed. (The functions of the inner ear are retained.) *Treatment:* A metallic pinna to match the left was modelled. *Attachment:* No mechanical means. Spirit-gum secures a perfect adhesion. The artificial pinna is only liberated with difficulty.

CASE 2.—*Injury:* Loss of nasal bones and cartilages, nasal process of frontal and superficial portions of both zygomatic processes of superior maxillæ. (After healing, by a slight operation, some nasal breathing was restored.) *Treatment:* Modelled metallic nose. *Attachment:* Spectacles, soldered on to the plate at bridge of nose. (Very simple, but quite effective.)

CASE 3.—*Injury:* Loss of nasal bones and upper part of cartilages, part of zygomatic process of superior maxillæ and right eye. *Treatment:* Metallic plate about 4 inches by 3 inches, inclusive of artificial nose and cheek, artificial eye and metallic eyelashes. *Attachment:* Spectacles on plate at bridge of nose, with a pillar fastening the limb of the spectacles to the side of the plate on the cheek-bone. For this extensive plate further security is obtained by the internal pressure of the fleshy terminal remains of the nose which becomes straightened when the mask is worn and fits into the plate. (Due care is taken to prevent discomfort by the pressure.)

Note.—In this photograph a special effort was made to indicate the plate-line (edges of the plate) by placing the camera only 3 feet from the patient. This to exhibit clearly the area covered. As a general rule the edges are not readily apparent.

CASE 4.—*Injury:* Effects of rodent ulcer and treatment. Lower face and nose. Loss of cartilaginous portion of nose, greater portion of alveolar part of superior maxillæ and symphysis menti, including on each side 1½ inches of the rami. (There is no control of salivation.) One aperture only serves the double purpose of respiration and alimentation. *Treatment:* An extensive mask, with modelled nose, lips, chin, &c., from bridge of nose to the cicatrice on neck; laterally fitting under both cheek-bones. *Attachments:* (1) Spectacles (which are detachable) fitting on bridge of nose; and (2) narrow ribbon, slotted through lower section of mask in front of throat, tied at back of neck. (The mask is worn with the greatest comfort and a large wad is fixed in the ample interior space for absorption of the effects of involuntary salivation, giving the patient increased comfort as well as the cosmetic advantage. The patient removes the mask when feeding and uses a feeding-cup.)

ALBUMINURIA IN THE TRENCHES.

BY H. B. F. DIXON, M.B., B.CH., B.A.O. DUB.,
MILITARY CROSS;
CAPTAIN, ROYAL ARMY MEDICAL CORPS (T.F.).

IN view of the investigations on albuminuria and trench nephritis that are now being carried out in casualty clearing stations and base hospitals, the following figures from the records of a field ambulance may perhaps serve a useful purpose.

Many patients are treated entirely in a field ambulance; others stay for several days before being sent down the line. In this field ambulance, during the months of December, 1916, and January and February, 1917, the testing of every patient's urine was adopted as a routine precedure. The results obtained are sufficiently interesting to warrant their being placed on record. In the three months under review all the sick of the division passed through this field ambulance, and the urines of all these patients were tested.

For the purpose of collecting the urine from large numbers pickle-jars were used, and proved very good substitutes for the specimen glasses of the general hospital. With the resources of a field ambulance the tests were simple. Acidulation and boiling, cold nitric acid were the tests used. No microscope, centrifuge, or other apparatus was available.

The following are the figures for the three months. The number of urines tested was 4085; the number of urines

showing albumin was 858 (21 per cent.), made up as follows:—

Showing a trace of albumin	596 (69·5 per cent.)	
,, cloud ,, ...	136 (15·9 ,,)	
In which the urine was loaded with albumin ...	126 (14·7 ,,)	

An attempt was made to ascertain (1) in what percentage of cases the albumin persisted and for how long; (2) what proportion of cases presented renal symptoms; and (3) the relation of patient's temperature to albumin in the urine.

All the cases referred to in this paper are based on observations made during periods varying from two to seven days.

—The figures for February, 1917, alone are given. The number of cases tested was 1442; the number of cases showing albumin was 310 (21·5 per cent.), made up as follows:—

Showing a trace of albumin	225 (72·6 per cent.)	
,, cloud ,, ...	56 (18·1 ,,)	
In which the urine was loaded with albumin ...	29 (9·4 ,,)	

1. *In what percentage of cases albumin persisted and for how long.*—Of these 310 cases, (*a*) albumin disappeared from the urine in 132 cases (42·5 per cent.), made up as follows:—

On the second day in 72 cases	54·6 per cent.		
,, third ,, 30 ,, ...	22·7	,,	
,, fourth ,, 12 ,, ...	9·1	,,	
,, fifth ,, 13 ,, ...	9·9	,,	
,, sixth ,, 2 ,, ...	1·5	,,	
,, seventh ,, 3 ,, ...	2·3	,,	

One hundred of these patients returned to duty, their urine having been clear of albumin for three days. Up to the time of writing (March 25th) there have been no readmissions for albuminuria, and although some of them have been re-admitted for various diseases, no albumin has been found in their urine.

I have been unable to trace the remaining 32, as they were evacuated to a casualty clearing station with various diseases—P.U.O., bronchitis, trench feet, &c.

From the above table it is seen that of the 310 patients in whom albumin was found on admission 132 cleared up within seven days, and of these 132, 100 returned to duty.

None of these patients presented any renal symptoms and only very few any constitutional symptoms. They were mostly cases of inflammatory connective tissue, scabies, impetigo, dental caries, laryngitis, &c.

(*b*) One hundred and seventy-eight cases in which albumin persisted in the urine while in the field ambulance. These cases were evacuated to a casualty clearing station, after periods varying from two to seven days, for P.U.O., bronchitis, pneumonia, &c., or albuminuria. Albumin persisted in the urine.

On the second day in 82 cases	46·1 per cent.		
,, third ,, 28 ,, ...	15·7	,,	
,, fourth ,, 12 ,, ...	6·7	,,	
,, fifth ,, 14 ,, ...	7·9	,,	
,, sixth ,, 23 ,, ...	12·9	,,	
,, seventh ,, 19 ,, ...	10·7	,,	

From the above table it will be seen that albumin was still present on evacuation to a casualty clearing station in 178 out of the 310 cases showing it on admission—i.e., 57·4 per cent., or 12·3 per cent. of the total patients admitted to the field ambulance for the month.

I have traced these 178 cases to the casualty clearing station, and find that 90 (50·6 per cent.) were transferred to base by hospital train as albuminuria or nephritis after a stay in the casualty clearing station of from two to eight days. The remaining 88 I have also traced and find that they were evacuated to the base with other diseases, P.U.O., bronchitis, pneumonia, &c. I have been unable to find whether albumin was present in the urine when leaving the casualty clearing station or not. None of these 88 patients presented renal symptoms while in the field ambulance.

2. *What proportion of the cases admitted with albumin in the urine presented renal symptoms.*—Of the 90 cases evacuated to the base with the diagnosis of albuminuria or nephritis 40 presented no obvious renal symptoms except in some cases a persistent albuminuria which increased from trace to cloudy, although on a milk diet; some cleared up on milk, but relapsed at once on being given meat.

Fifty patients showed distinct renal symptoms whilst in the field ambulance. A short account of their condition follows.

History.—Four patients suffered from renal disease in civil life. One patient had been in the ambulance three weeks previously with trench fever, and then had a trace of albumin which persisted for two days. He was discharged on the eighth day apparently well. The majority of patients gave no history of previous illness.

Onset.—Rapid. In most cases patient stated he had been feeling ill for about 2-5 days. The first thing usually complained of was pain in the back and legs, then shortness of breath and puffiness of the legs and face. In four cases the reddish colour of the urine was the first thing noticed.

Symptoms.—There occurred in the following order of frequency: Bronchitis, 16; swelling of feet and legs, 14; hæmaturia, 13; shortness of breath, 12; headache, 6; frequency of micturition, 5; vomiting, 2; and cyanosis, 2. Some patients had only one or two of these symptoms, others more.

Urine.—In 23 patients the urine was loaded with albumin.
,, 26 ,, ,, ,, cloudy.
,, 1 ,, ,, contained a trace.

Temperature.—This was raised in 23 cases, normal or sub-normal in 27.

Cardiac changes were observed in 2 cases.

Two cases died. Both presented while in the field ambulance symptoms of uræmia, with cyanosis of a grey type.

The length of service in France of the 50 cases showing renal symptoms is as follows: Up to 3 months, 16; 4 to 6 months, 8; 7 to 12 months, 15; 12 to 24 months, 11.

The age incidence of the 50 cases showing renal symptoms is as follows: 18 to 25 years, 28; 26 to 30 years, 8; 31 to 35 years, 7; 36 to 40 years, 4; and 40 years and over, 3.

The majority of the cases were infantry serving in the trenches. The average per battalion was 4. A pioneer battalion gave the greatest number of cases—i.e., 6; the A.S.C. furnished 3, Division Ammunition Column 3, R.A.M.C. 3.

3. *Relation of patient's temperature to albumin in the urine.* (From the charts of cases which remained in the field ambulance for four days or more.):—

	Cases.
Patients' temperatures normal during stay in hospital (albumin disappeared within 7 days)	65
Patients' temperatures normal during stay in hospital (albumin remained)	47
Patients' temperatures fell to normal (albumin disappeared) ...	38
Patients' temperatures fell to normal (albumin remained) ...	31
Patients' temperatures remained high (albumin disappeared) ...	21
Patients' temperatures remained high (albumin remained) ...	20
Total	222

Albumin was found in 25 per cent. of the cases of P.U.O. admitted during the month of February, 1917.

Conclusions.

It is extremely difficult to draw any conclusions from the work done in a field ambulance, as the facilities are few and the time for observation limited. A few points and suggestions, however, may be helpful to others who have better opportunities for research.

One point impressed on the author during the past three months is the importance of testing the urine of every sick man.

Of the 50 severe cases referred to in an earlier part of the paper only 15 presented symptoms sufficiently obvious to enable the diagnosis of albuminuria to be made before reaching the ambulance. The remainder were admitted with other conditions, such as P.U.O., bronchitis, inflammatory connective tissue, tonsillitis, or even scabies.

I have also been struck by the large number of patients who, without renal or constitutional symptoms, show a trace of albumin in their urine. These cases are sent in to the field ambulance for complaints which do not seem to bear the slightest connexion with albuminuria—e.g., hernia, flat feet, varicose veins, scabies, impetigo, dental caries, and minor septic conditions. Some of these cases give a trace of albumin for a few days, which clears up under treatment and does not recur. The condition does not seem to bear any relation to the severe type of albuminuria, for of the slight cases which cleared up while in the ambulance and returned to duty only one has been readmitted. In this case the urine was loaded with albumin on readmission. This mild albuminuria is also met with in officers; 32 per cent. of those admitted showed albumin, but no case showing renal symptoms has been observed in the three months. In all cases amongst officers except two the albumin cleared up in a few days. This mild albuminuria appears to be physiological, possibly due to the conditions of life in the trenches, where excessive ingestion of protein, excessive fatigue, and exposure are common.

As regards the relation of temperature to albuminuria I have not been able to draw any definite conclusions. Patients

with a high temperature seldom have albumin, whilst those with lower temperatures frequently have. The true febrile albuminuria of the text-books, where the albumin disappears with the fall of temperature, has not often been seen, the temperature often falling while the albumin remains, and *vice versa*, in a most bewildering fashion.

That there is a definite trench nephritis there is no doubt in my mind, possibly an infective condition similar to the acute nephritis of civil life, but the anæmia does not seem to be so common. Suppression of urine has not occurred in any of the cases under observation. The respiratory system seems to be first attacked.

Cardiac changes have not been observed. With the resources at my disposal I have not been able to classify the severe cases, but I feel sure that they could be grouped in some such manner as: (1) Cases of old nephritis awakened again by climatic conditions in the trenches; (2) cases of acute nephritis which would have occurred in civil life; and (3) cases of trench nephritis.

It is hoped that this paper will prove some stimulus to the further investigation of albuminuria in the field, as the foregoing figures show that patients suffering from various ailments are frequently found upon examination to be suffering from albuminuria, which in many cases gives rise to no symptoms.

A UNIVERSAL ARM-SPLINT.

BY GEO. EWART WILSON, M.B. TOR., F.R.C.S. ENG.,
CAPTAIN, CANADIAN ARMY MEDICAL CORPS.

THE surgeon who has had to treat many cases of compound fracture of the humerus with suppuration must have felt how unsatisfactory were any of the splints at his disposal, and it was such a feeling that induced me to endeavour to work out a splint which should at any rate approach the ideal. It is not my purpose to discuss in any way the various splints in use at the present time, but simply to describe as briefly as possible the methods I employ.

The splint is made of a single rod of one-quarter inch round malleable iron, about seven feet long. It should not bend too easily, and is twisted cold. For descriptive purposes it may be divided into a chest-piece and an arm-piece. (See Figs. 1 and 2.) The former is shaped like the letter "W," and as it is the part which is attached to the chest wall, its curves conform to the antero-lateral outline of an average thorax. The latter consists of two limbs, an anterior and a posterior. The anterior turns immediately downwards and a little forward, with a fairly sharp bend at an angle of about 30°, forming the inner bar; and at a place corresponding to the bend of the elbow, turns directly inwards as the upper bar. The posterior passes outwards at right angles to the plane of the chest-piece, forming the projecting bar, until it reaches the level of the plane of the anterior arm, when it turns downwards parallel to the inner bar, forming the outer bar. Below the elbow it turns inwards as the lower bar, and at a suitable spot turns upwards to join the extremity of the anterior limb as the end bar. The measurements of the various parts of the arm-piece are as follows:—Projection bar, 6½ in.; inner bar, 5½ in.; outer bar, 13 in.; upper bar, 10 in.; lower bar, 16 in.; end bar, 4¼ in.

FIG. 1.

Chest-piece.

While it is desirable to have a war splint as simple as possible, it is very apparent that the model described may be modified. For instance, there might be a lock-joint where each limb joins the chest-piece; or steel might be used to replace the malleable iron, but for the universal use the latter is preferable, because once the plaster is firmly set, the position of the splint can be changed by simply bending it where the anterior and posterior limbs join the chest-piece, provided, of course, the material is of the proper strength.

FIG. 2.

Arm-piece.

The splint is applied as follows:—

The patient stands, or is seated on a high stool with a foot rest. A tight-fitting vest (undershirt), with the sleeve cut away from the side corresponding to the fracture, is put on and the fractured arm is held forward by an assistant, while he rests his good arm on the assistant's shoulder. It is important that the patient stand or sit erect with the shoulders in a position of rest, so that when the arm is applied to the splint the parts are in a natural posture. Three 3-inch plaster bandages are put round the chest, reaching into each axilla as far as one can comfortably go, and embracing the lower borders of the ribs in the axillary line. These must be put on snugly, for if loose, the cast will be uncomfortable. Now apply the splint, taking care that the plane of the arm-piece is directed forward, and the upper ends of the "W" are about the level of the top of the plaster. In this position try the arm, and if the elbow is going to be too near the lower bar, pull the chest-piece a bit lower. The arm is again held aside, and while an assistant holds the splint in position, some plaster cream is rapidly rubbed about the "W," and then two or three more bandages are applied. By the time a small crescent-shaped piece of plaster is cut away from each axilla, the splint should be fairly well fixed, and ready to support the arm. While the plaster bandages are being applied, shoulder-straps of adhesive strapping about three inches wide and having a pad for the protection of the clavicle are incorporated.

The flannel slings previously fixed to the splint are brought into position and the arm placed upon them. Extension is applied by adhesive bands front and back and attached to the lower bar. If the splint has been properly applied the humerus is directed downwards and slightly forward and the forearm across the body with the hand grasping the end bar. If there is any danger of pus tracking up towards the shoulder when lying down the patient is preferably put upon a Gatch frame.

The advantages of this method are manifold: it is simple, cheap, quickly made, and readily transported. Once applied it will remain in place for weeks without further attention. The whole weight of the limb is borne by the trunk, so that the shoulder-girdle is relaxed. It gives fixation of the fragments which is permanent and as much or little extension—for with a relaxed shoulder very little is required—as is desirable, without any pressure whatever upon the axilla. While designed for the humerus, it is just as applicable for the forearm, in which case the extension is made from the lower end of the outer bar; and if it is necessary to have the hand supinated the upper and lower bars can be twisted accordingly. Correct alignment is readily obtained, for the whole arm is exposed to anterior

and lateral views. The space between the bars is sufficient for the wounds to be easily and quickly dressed and with the minimum of pain, because the forearm remains fixed. The patients are comfortable, and unless otherwise contra-indicated they are free to move about at will, and whether up or lying down there is no change in the support of the arm, since the flannel slings run parallel to the transverse diameter of the body. The nursing is reduced to a minimum, and if the patient must remain in bed he is as easily managed as one with a septic arm but without a fracture. While one model for each side suffices. it is more convenient to have different sizes, but in a short man the splint is put on high up, while in a tall man lower down. It can be made anywhere, as any surgeon with a hammer and anvil should experience no difficulty in turning out a model from which as many as desirable may be made.

I have at present a leg-splint based on the same principle —namely, the permanent fixation of the splint to the trunk, so that the limb is applied to the splint and not the splint to the limb. In the near future I propose describing it in detail.

I would like to thank Lieutenant-Colonel W. B. Hendry for the kindness shown me. He has given me every opportunity to use his patients to experiment with the splint, and, in fact, it was upon a patient of his that I fitted my first model.

TEMPORARY "PILONS."

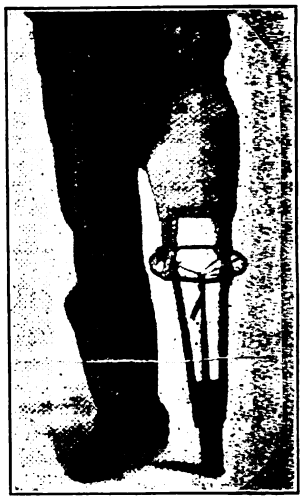
BY DR. A. H. BIZARRO,

LATE INTERNE OF THE LISBON HOSPITALS; ASSISTANT SURGEON TO WELSH METROPOLITAN WAR HOSPITAL, WHITCHURCH, NEAR CARDIFF.

THE word "pilon" is used in French-speaking countries for pestle or stamper. It means, from an orthopædic point of view, any device of prosthesis to enable cases of amputation to use their stumps for deambulatory purposes. Considering the great number of amputations during the war, and the drawbacks of keeping patients without using their stumps before being fitted with artificial limbs, any temporary appliance to enable patients to walk while awaiting complete healing of the stump and all other details required

FIG. 1.

Temporary pilons as applied to amputations through the thigh.



for the application of a definite artificial apparatus, would be of great practical use. Professor Depage and Dr. Martin (Belgium) were in their clinic among the first to make use of temporary pilons in these cases.

It is unnecessary to state the disadvantages of keeping an amputated limb in disuse for a prolonged period. The stump is liable to various types of deformities impairing the function of the joints, to œdema, terminal adhesions of the scar, hypersensibility, &c. The use of crutches may not only provoke and accentuate all these alterations, but will give rise to postural deformities of the body by reason of deviation of its gravitation centre as a whole. Besides, crutches can give rise to various inconveniences by pressure on vessels and nerves in the axillary region and on the points of contact of the hand due to grasping the handle.

Any temporary device that allows such cases to walk soon after the amputation has advantages which can be easily foreseen. The cicatricial processes are quickened, the stump gets used sooner to its proper work, the stay of the patient in hospital as a convalescent is shortened, and the definite artificial limb can be applied in much better conditions for a quick practical success, saving most certainly a sum of money in the great majority of cases. Besides, the pilons I have made can last several months in good condition for daily use.

The material required consists of a wooden frame, easily made, poroplastic, webbing, plaster, bandages, and a little felt. The first step in applying a pilon is to make a mould of the stump with poroplastic. With the patient standing (particularly in thigh cases) on the sound leg the bony tuberosities should be well marked, and the upper end of the first layer well adapted to them so as to support the weight of the body in walking. The lower end of this first layer, in the great majority of cases, is left open, and all the support of body takes place on the superior part of the tube.

FIG. 2.

The temporary pilon with extension applied.

Having moulded and fixed this inner coat of the pilon, keeping it very smooth on its inner face, it is covered with a few layers of plaster. Then, having tried it well on the patient, the wooden frame is measured, allowing for the heel of the boot, and is fixed to the inner cylinder by means of plaster. Webbing pieces are included in it, and when the plaster is dry, the inner cylinder is fixed to the frame by means of screws or rivets to make the whole more solid. For stumps of the thigh felt only is used on the upper part of the poroplastic, and I must emphasise that in these cases the bottom of the cylinder is entirely open.

To avoid softening of the structure of the cylinder due to perspiration, particularly in warm weather, holes of 5 cm. diameter can be drilled through the supporting belt which at the same time makes the pilon lighter.

The cheapest form of wooden frame is a short cylinder 5 to 10 cm. long and 5 to 7 cm. in diameter according to site of amputation, with two bars of different length on either side of it. These are fixed to the former by screws, and the "heel" can be covered by a circular rubber heel or a piece of leather.

Short stumps of the thigh require a long outer wall of the pilon, and good fixation to the trunk by means of a lateral bar of iron. I have a special design of articulation which has not yet been tried in this service. For short stumps of the leg good results are usually achieved by making a secondary cylinder for the thigh and fixing it to the lower one by a bilateral articulated piece opposite the knee.

Patients fitted with pilons are allowed to walk, using walking-sticks, and in a short time they recover good co-ordination of movements and muscular power of the stump, getting about without any manual means of support. In cases requiring extension of the soft parts this can be applied to the lower end of the pilon by means of an india-rubber tubing. (Fig. 2.) When the patient goes to bed it can then be applied to the weight as in the usual cases. The photographs reproduced elucidate the pilon better than any detailed account.

These temporary pilons cost very little, and as a rule last for a very long time. When the stump gets thinner the bucket can be made to fit the thigh better by a thin layer of felt conveniently applied on its inner surface. The appliances save time, give great moral comfort to the patients, and in the long run save money, not only as regards the fitting of the definite artificial limb, but also in diminishing the period of in-hospital treatment. In a word, they make the cases more anatomical in a shorter period of time. I have a similar device for the upper limb which has not yet been tried in this country.

My thanks are due to Lieutenant-Colonel E. Goodall, officer in command of the Welsh Metropolitan War Hospital, and Lieutenant-Colonel Lynn Thomas, C.B., C.M.G., consulting surgeon, who introduced the pilons into the hospital, and to Mr. Geary Grant, the surgeon, whose cases kindly were given to me for the carrying out of the work.

A CASE OF

PHARYNGEAL DIVERTICULUM.

BY JAMES McCLURE, M.D. GLASG., F.R.C.S. ENG.,
ASSISTANT SURGEON, LONDON TEMPERANCE HOSPITAL.

I DESIRE to draw attention particularly to two points of importance in the diagnosis of pharyngeal diverticulum. In the first place, in a suspected case, where a negative radiographic examination has taken place, undue weight should not be attached to this, but further examinations should be carried out subsequently and attempts made to imitate the average consistency of the regurgitated material in preparing the opaque meal. Secondly, though the natural secretion from the mucous membrane of the pharynx and œsophagus is alkaline, yet food retained in a pharyngeal pouch may rapidly decompose, and a strongly acid reaction therefore should not lead one to conclude that the regurgitated food must have come from the stomach. The acidity in the following case was due to lactic and not to hydrochloric acid.

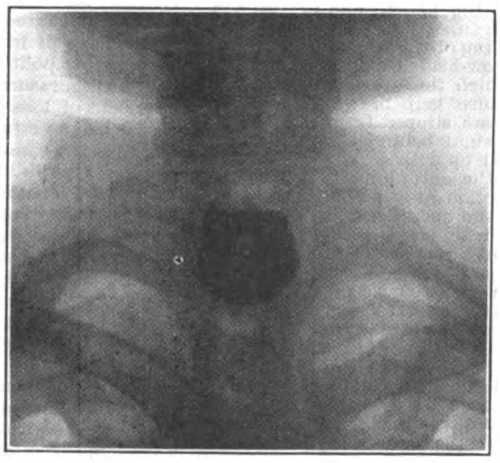
A. B., aged 44, consulted me on Feb. 8th last on the advice of his medical attendant. He stated that, at intervals varying from 2 to 24 hours after swallowing food, regurgitation of small particles took place into his mouth. This was painless, unassociated with effort or nausea, and had occurred at irregular intervals over a period of at least three years. In addition, for the last two or three months he had been troubled occasionally with "sour mouthfuls" and a bad taste in his mouth. His doctor told me that he had been radiographed for a pharyngeal pouch with negative results, that the regurgitated food had invariably been found to be strongly acid, and that after the passage of bougies under an anæsthetic a diagnosis of œsophageal spasm had been offered by the surgeon who saw him at that time.

Previous history.—He had had no previous illness of any importance, gave no history of syphilis, and had always led a careful and abstemious life; but he worried about trifles, he said, and remarked that his present disability was more pronounced when he had had more worry than he could "shake off." His teeth, which had always been bad, were extracted nine years ago and replaced by dentures. Even then, however, he never masticated his food thoroughly, and especially during the last two years he used to bolt his food in consequence of increased work and hurried meals.

History of present condition.—During the winter of 1914–15 he had been singing more than usual, and in his professional capacity had put such an extra strain upon his voice that he had to consult a laryngologist about a dry and painful throat. On that occasion he spoke for the first time to any doctor about the return of food into his mouth. He did so because he felt there was some "slight stoppage just behind the throat," and thinking this stoppage and the soreness of the throat were due to one and the same cause he concluded that the throat examination would show what was wrong. Under treatment his throat symptoms improved, but the regurgitation of food persisted. As this was painless, he waited till May, 1916, when a recurrence of throat trouble made him consult his doctor, who told him that he probably had a pharyngeal pouch and advised him to see a surgeon. He did so, and after examination was told he was suffering from "nervous spasm of the muscle."

Examination.—I saw the patient with his doctor on Feb. 8th. In addition to the history given above, he told me that mouthfuls of a white frothy substance used to enter his mouth with a gurgling noise, especially when he stooped down to tie his shoe-laces in the morning. He had no difficulty in swallowing liquid or solid food; but he felt as though some food "lodged" or stuck at times just behind his throat. He had not noticed that this occurred with his head in any one position more than in another. After a violent fit of coughing or hawking of mucus, food used to regurgitate more freely. Currants, haricot beans, sardine and aperient pills were the most likely to "lodge and come back." In ordinary social intercourse he was always apprehensive of regurgitation taking place accompanied by gurgling noises. Eighteen months ago he weighed 11 st.; his weight was now 10 st. 3½lb.

External examination revealed no fullness of the neck except for some slight enlargement of the thyroid gland. In examining this a gurgling noise was heard inside the mouth. This was repeated when holding the tongue forward in the course of an examination of the larynx. This gurgling could be heard distinctly some yards away: it lasted about five seconds and was apparently due to the escape of gas from his pharynx; the gas was odourless. A full-sized gum-elastic bougie was passed into the stomach without difficulty, but shortly afterwards the soft tube of a Senoran's aspirator was arrested about 7 inches from the teeth. A provisional diagnosis of pharyngeal diverticulum was given and operative treatment for its removal was advised if X ray examination confirmed the diagnosis.



X ray examination.—The patient was X rayed by Mr. Archibald Reid on Feb. 12th. About 8 ounces of barium emulsion were prepared and specially made of a thicker consistency than usual. While the patient lay on a couch in a semi-recumbent posture he was told to swallow half of the emulsion slowly and in small quanties at a time. Five minutes afterwards he was allowed to get up and was then screened in the right oblique and postero-anterior positions.

In the right oblique position nothing abnormal was seen at first in the region of the pharynx or œsophagus. A bismuth cachet was swallowed and this rapidly traversed the gullet and reached the stomach without delay.

More emulsion was given and in the postero-anterior position a small crescentic shadow was observed behind the tracheal rings. Though the pouch contained but a small quantity of emulsion, the shadow cast by the barium could be seen rising and falling with every effort at deglutition. Sufficient evidence was thus obtained to confirm the clinical diagnosis. It was now possible towards the end of the examination to see the shadow in the right oblique as well as in the postero-anterior positions. A subsequent attempt was made to fill the sac more completely. This succeeded, and Figs. A and B are the appearances seen in the skiagrams. It will be observed that the lower margin of the shadow reaches to the level of the body of the second dorsal vertebra.

Skiagrams showing Rounded Outline and Broad Pharyngeal Attachment of Pouch.

FIG. A.

Postero-anterior view.

FIG. B.

Right oblique view.

Operation on Feb. 18th.—Intratracheal insufflation of ether was carried out by Dr. Howard Jones, and with the assistance of the patient's doctor and Mr. Neil Sinclair the œsophagus was exposed by an incision along the anterior border of the left sterno-mastoid muscle from the sterno-clavicular articulation to the upper border of the thyroid cartilage. A distended anterior jugular vein, which appeared to lie farther from the middle line and to cross below the sterno-mastoid at a higher level than usual, was cut between two ligatures. The sterno-mastoid muscle with the carotid sheath was drawn outwards, exposing the infrahyoid muscles. The anterior belly of the omohyoid was divided, and its nerve of supply

from the ansa hypoglossi was seen entering its deep surface towards the posterior border. Retraction inwards of the sterno-hyoid and sterno-thyroid muscles showed up the pretracheal layer of fascia which was very well marked. Division of this enabled the lobe of the thyroid to be displaced towards the middle line, exposing a cavity in which the finger recognised the vertebræ posteriorly and the cricoid and tracheal rings anteriorly. A strand of fibrous tissue prevented complete retraction forwards of the thyroid. This contained the inferior thyroid artery, which was isolated by blunt dissection. After division of its upper and lower branches between two ligatures complete dislocation forwards of the thyroid lobe was possible. A 10-volt Clar's forehead lamp was found useful at this stage. Embedded in the pale pink areolar tissue of the depth of the cavity a thicker and more substantial-looking structure could be seen distinctly. It was white with rounded outline and proved to be the pouch.

A full-sized stomach-tube was passed into the stomach and left in position till the operation was completed. Alongside this an ordinary gum-elastic catheter was introduced and, guided by the finger in the wound, was coaxed into the diverticulum. This helped to demonstrate its size and rendered easier the separation of the sac, while the stomach-tube acted as a guide for its complete isolation right up to its junction with the pharynx. No inflammatory adhesions were encountered and the pouch was easily freed by blunt dissection from the surrounding tissues. There was no displacement of the carotid sheath and, with the exception of the slight irregularity in position of the anterior jugular vein (noted above) and some enlargement of the lobe of the thyroid gland, no anatomical peculiarities were noted. The œsophagus was freed to some extent from the loose areolar tissue over the longus colli muscle, and in this way the pouch and adjacent part of the gullet were brought as near as possible to the surface of the neck wound. The pouch was more or less globular, semi-collapsed, and about the size of a golf ball. It was attached to the middle of the posterior surface of the pharyngo-œsophageal junction, about the level of the cricoid cartilage. Its communication with the œsophagus was not narrowed down to form an isthmus, but was relatively wide and open, measuring about 1 inch in vertical diameter. No stricture was seen in any part of the œsophagus so far as this was exposed from the cricoid downwards. In isolating the sac some of its contents were expressed into the pharynx, but aspiration of any septic material was effectually prevented by the steady expiratory current of air alongside the intratracheal catheter.

The catheter was now withdrawn from the pouch, and after packing off the cervical tissues with gauze the diverticulum was removed. To prevent any soiling of the wound this was done between two pairs of narrow-bladed clamp forceps, but owing to the tension with which the sac was brought to the surface and to the insecure grip of the proximal pair of forceps the stump of the sac slipped from between the blades and retracted out of sight behind the gullet. Each end of the opening was picked up with a pair of Porrier's forceps, and this made easier the only difficult part of the operation—namely, the introduction of a double layer of continuous catgut suture to close the opening. On account of the depth and narrow space in which one has to work, a Killian's nasal septum needle might prove useful in introducing these sutures in any similar case. The first row of sutures took up the mucosa, while the second buried the first by approximating the fibrous and muscular coat. Finally, two or three points of interrupted suture were inserted, bringing down the lower fibres of the inferior constrictor of the pharynx to reinforce the upper angle of the wound. The wound was cleaned and wiped dry and a medium-sized rubber drainage-tube was placed down to the suture line in the œsophagus and brought out at the lower angle of the wound. The cut margins of the platysma were approximated with interrupted catgut sutures and silkworm gut brought the wound together except where the tube emerged below. With the exception of these silkworm gut sutures catgut ligatures were used throughout. The stomach was washed out through the stomach-tube, and the latter was then withdrawn.

For the first two days the evening temperature registered 100° F. Its highest point thereafter was 99° F. and by the end of the first week it was normal. The drainage-tube was removed on the fourth day and replaced by a light gauze wick, which was discarded on the tenth day. No food fistula developed and the sinus gradually closed down. For the first four days nothing was given by the mouth, which was constantly rinsed with glyco-thymoline mouthwash. During this time salines and glucose were given per rectum, and on the fifth day sterilised milk, raw meat juice, and chicken jelly were allowed. The amount and frequency of oral feeding were gradually increased, when it was seen that no leakage had occurred, and when he left the nursing home for Brighton at the end of the third week he was taking solids easily and with comfort.

I am much indebted to Captain C. Rhodes Harrison, R.A.M.C. (T.), who sends the following histological report of the diverticulum:—

"On section two small ulcers were found each about the size of a threepenny-piece and in the removed position they were in apposition. They showed loss of epithelium, the bases being formed of firm connective tissue in a condition of subacute inflammation. The epithelium throughout was of the type normal to the œsophagus. In no place was there evidence of peptic or other glands and there was no keratin formation. The wall showed a fairly firm fibrous connective tissue with very scanty and isolated groups of muscular tissue."

Mr. John Webster, F.I.C., of the Laboratory of Pathological Chemistry, St. Mary's Hospital, kindly analysed the contents of the pouch. He reports as follows:—

"The filtrate was strongly acid to litmus, but gave no acid reaction with dimethylamidoazobenzene nor with Gunzburg's reagent. The acidity was due not to mineral acid but to organic acid or acid salts. The liquid gave a marked reaction for lactic acid. On examination for ferment activity I found no evidence of the presence of pepsin or pepsinogen."

ROYAL SOCIETY OF MEDICINE.

SECTION OF OPHTHALMOLOGY.

Discussion on the Etiology and Treatment of Iritis.

A MEETING of this section was held on June 13th, Mr. WILLIAM LANG, the President, being in the chair.

The PRESIDENT made touching reference to the demise of Mr. Walter H. H. Jessop, who was at the time of his illness acting as honorary librarian to the Bowman Library and had expressed his intention of making the library as perfect as possible. Owing to the generosity of Mrs. Jessop the deceased Fellow's books had become part of the library, and for this all ophthalmologists had cause to be grateful.

In initiating the debate on the Etiology and Treatment of Iritis, the PRESIDENT said that its opportuneness lay in the fact that if Fellows could agree as to the cause of the disease in the majority of cases of iritis they would be in a strong position should it appear politic to advise the proper authorities to introduce such measures as would prevent much ill-health, a great amount of loss of sight, and untold injury to the community. He had ascertained that in 200 cases of iritis in his private practice the various causes occurred in the following percentages: syphilis, 6; gonorrhœa, 12; tubercle, 11; general affections, 8·5; other causes, 25·5; pyorrhœa, 37. At one time, syphilis was regarded as the chief cause of iritis, and probably hospital figures would show an increase on 6 per cent.; but with the modern anti-syphilitic methods he thought it would become the rarest cause, for gummata of iris and ciliary body could be made to melt away without the disorganisation of the eye which was formerly seen. Gonorrhœa was not usually considered so potent a cause, but hospital practice would probably show a higher percentage than 12. Until recently Mackenzie's work on gonorrhœal iritis had remained unimproved upon. Now, however, that the infection had been shown to linger in the genito-urinary system for years relapses could be largely prevented by local treatment applied in that region. Other sources of infection might complicate the cases of iritis, such as pyorrhœa, and produce relapses. The tuberculous cases of iritis were equally divided between the sexes, and the average age of the patients in this form was 25 years, all but two being between 16 and 35 years of age. The treatment of tuberculous iritis, as for tubercle of the lung, appeared to be good air, graduated exercise, and food rich in fats, as well as such local measures as would subdue inflammation and prevent closure of the pupil. Of the cases 17 were associated with gout, diabetes, herpes of the fifth nerve, influenza, and pneumonia. Ten patients had some septic focus on the skin or on a mucous membrane or cavity. In 6 cases there was disease of tonsils, and 23 patients had an affection of the alimentary tract, while 7 had a diseased condition of the genito-urinary system. One case followed a smart blow on the eye, and another patient had iritis as a sequel of sympathetic ophthalmia.

In no less than 74 of the 200 patients the sole cause found was pyorrhœa. When these cases were seen early and the offending stumps or teeth were removed the clearing up of the iritis was strikingly rapid. Of the remaining cases 22 had pyorrhœa in association with other diseased condition. In the cases in which pyorrhœa alone was found there were twice as many women as men. Of the total number 48 per cent. had their mouths affected, and it would be of great value if members of the dental profession could recommend a preventive of this appalling state of affairs, which seemed to lay the foundation for numberless diseases involving all parts of the anatomy, including the eye.

Sir ANDERSON CRITCHETT directed his remarks to the treatment of iritis. Forty years ago Sir John Tweedy made the suggestion that in many cases where atropine proved ineffective the sulphate of duboisine was a more powerful mydriatic, and in some cases he had found that where atropine was practically powerless he had been able to break down synechiæ with the more powerful drug. It was never necessary to use more than 2 grains to the ounce, the equivalent of 6 or 8 grains of atropine. It must not be allowed to pass down the duct into the throat. Leeches he still regarded as very useful in the early stages. Gonorrhœa was admittedly a frequent cause of iritis. He quoted the opinion of the late Mr. Nettleship as to the real good conferred by iridectomy in some cases of iritis, but the procedure was contra-indicated in keratitis punctata, chronic thickening of the iris with very extensive synechiæ, and the existence of myopia. Mr. Nettleship considered it a mistake to reserve that procedure until all other plans of treatment had been patiently tried. In his (Sir Anderson Critchett's) own experience few things had impressed him more than the extraordinary value of iridectomy both as a preventive and as a curative agent in the cases for which it was specially appropriate. But it must be a good iridectomy.

Mr. J. G. TURNER discussed the subject from the standpoint of the odontologist, and referred to the work he did with the late John Griffith in trying to trace the relationship between dental sepsis and eye diseases, based upon the observed connexion between gonorrhœa and iritis. Probably the causal agent was an infection by means of the blood stream or lymph stream, either toxic or, more probably, actually microbial, and seldom by direct continuity of tissue. Only seldom was a mouth seen which was free from the possibility of infection, and even when the last tooth had gone and a plate was substituted the danger had not gone, for an artefact factor was introduced in the production of dental sepsis. When the periodontal sulcus was infected it was a practically undrainable area. When sticky food was eaten the area referred to close to the neck of the tooth was not cleansed, and a nidus was thus formed for the multiplication of germs. A second source of sepsis was by caries and a septic tooth. A dead tooth always was septic so long as it remained in the mouth. A German investigated a large number of dead roots, and he did not find one which was aseptic. There was nothing which would penetrate and follow up the minute canals of the dead root. "An eye for an eye and a tooth for a tooth" might stand, but a tooth for an eye was a bad bargain. Tooth-cleaning, to be really effective, should be taught by an expert. Most of the ordinary cleaning was futile, because it did not reach the gum edge; the lingual surfaces of the teeth were practically untouched. Much might be done in the way of prevention by avoiding sticky foods. He had looked through the skulls of various races and various ages of mankind, as well as skulls of animals, and they followed the one rule: Where the food was sticky, starchy, and sugary, decay and pyorrhœa were found; where the food was only meat, neither decay nor pyorrhœa existed.

Dr. H. LYON SMITH said he had been working at the causation of arthritic conditions for eight years, and the evidences which he had obtained that bacteria, or their toxins, were the chief causes of arthritic trouble were derived by studying vitiated conditions of blood, most of which he believed were brought about by bacteria. The toxins and the bacteria prepared the ground; it was the element of strain or injury which determined the site. Therefore he had considered it sound practice to recommend every arthritic person to have his refraction carefully tested by an expert, for he believed many cases of iritis might be prevented if eye-strain were avoided. It was long supposed that tubercle bacilli, gonococci, and the syphilitic virus were the only organisms capable of setting up iritis; but the bacteria of pyorrhœa and those concerned in nasal catarrh, bronchitis, colitis, urethritis, salpingitis, &c., were all equally capable of producing it. In August, 1915, he published a paper describing a test by direct hæmolysis as a method of detecting bacterial toxins in the blood, and he was not aware that the statements he then made had been contradicted. He examined the blood of 450 people, most of them suffering from chronic rheumatism or gout. In 8 iritis was a secondary trouble. In 4 of the cases the influenza bacillus or its toxin was answerable, in 3 the tubercle bacillus, and gonorrhœa in only 2 cases. The toxins of streptococci and staphylococci were present in all the 8 cases, and in 3 *B. pyocyaneus*, which latter was a very depressing organism and was a common inhabitant of the alimentary tract. The bacillus of influenza elaborated a great variety of toxins, many of which were specially prone to attack nerve tissue. He believed iritis was a not infrequent sequel of a severe attack of influenza. In treatment strong bodily reactions by means of injections must be avoided when the eye was involved. For example, when using tuberculin a commencement should be made with something less than 1/250,000th of a mgm. He had heard such a dose spoken of scornfully as too small to give an effect either way, but experiments with colloid mixtures showed definite effects from even billionth dilutions.

Captain A. W. ORMOND, R.A.M.C., thought Mr. Turner's contentions proved rather too much, for on his thesis iritis should be much more common than was the case, especially in out-patient ophthalmic practice, where the general run of mouths was deplorable. Did rheumatic fever produce iritis at all? He also asked for a scientific definition of gout. He did not think it possible that errors of refraction and eye-strain could cause iritis. An important point was as to the duration in an active stage of the gonococcus in the tissues; it had been said that it remained in the crypts of the prostate for 15 or more years, but that did not coincide with other statements. He found leeches very useful for iritis, but they were difficult to obtain. He found great comfort was obtained by the continuous application of the electric coil.

Mr. ERNEST CLARKE believed that a point of strain or traumatism was the point for the manifestation of gout when it was in the system. If the metatarsal joint was defective gout manifested itself there; if eye-strain were present, iritis would probably occur. He always tried correction of the latter before recommending iridectomy.

Dr. C. E. LAKIN said he could not remember an instance of a toxic case being associated with a local outpouring of inflammatory fluid. He strongly supported the view that in iritis a microbial infection was at work, due to an embolic process. He believed the reason the iris was affected was that at the junction of the iris and the ciliary body there was a change in vascularity from a highly vascular to (comparatively) an avascular arrangement, the latter containing less hæmoglobin and less oxygen, and hence organisms were able to flourish there.

Mr. LESLIE PATON related a case in which he was able to derive proof that the eye condition was directly due to the foul condition of a tooth stump. The case started as one of deep keratitis profunda, and iritis developed later.

The PRESIDENT replied on the various points raised.

DONATION TO DUNDEE ROYAL INFIRMARY.—At the annual meeting of the Dundee Royal Infirmary held on June 11th the chairman stated that the total expenditure for the year was £27,362, and the deficiency on the year's working was £10,089. This deficiency has been wiped off by Mrs. Marryat, of Belmont, sister of the late Sir James K. Caird, Bart., and the directors expressed their sincerest thanks to that lady for her great kindness. A further donation of £210, and legacies amounting to £250 were also intimated.

THE LATE DR. WINSLOW ANDERSON.—The death occurred in May in New York of Dr. Winslow Anderson, at the age of 57, who was for many years the editor of the *Pacific Medical Journal*. Dr. Anderson, who graduated at the University of San Francisco in 1884, later took the English double qualification, and proceeded to the Membership of the Royal College of Physicians of London. He was originally interested especially in pharmaceutical chemistry and materia medica, but later became professor of abdominal surgery and gynæcology in the College of Physicians and Surgeons of San Francisco, over which institution he was presiding at the time of his death.

Reviews and Notices of Books.

On Causation, with a Chapter on Belief. By CHARLES A. MERCIER, M.D., F.R.C.P., F.R.C.S. London: Longmans, Green, and Co. 1916. Pp. 228. Price 4s. net.

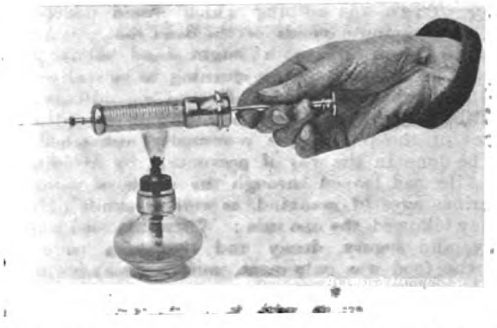
Dr. Mercier has a happy gift of infusing a strong vitality into every subject on which he writes; he possesses, moreover, many of the qualities of the first-class critic—namely, an incisive and entertaining literary style, a habit of going straight to the main points, and a mortal animosity towards all forms of pedantry and humbug. In his latest work all these characteristics are displayed to their fullest extent. Dr. Mercier has—one would almost think intentionally—looked round for the dullest and driest science he could find; he has pitched on logic, and seems to take a malicious satisfaction in re-animating that venerable study and in directing his shafts of criticism against its orthodox exponents. To admire Dr. Mercier's virility of method is, however, a different thing from endorsing all his conclusions. We venture to think that the main value of the book lies in the clean drive through the pedantry with which logic has been surrounded; the inherent heterodoxy or even iconoclasm; the freshness of its point of view. Dr. Mercier ignores or ridicules most of the work of his predecessors: his doctrines should cause the disciples of Aristotle to groan in their tombs. It often happens, however, that those who entirely cut the painter as regards the past, while gaining much in originality and vigour, lose somewhat in solidity of foundation. Dr. Mercier has not altogether escaped this danger. He begins by examining the theories of causation advanced by Hume, Mill, Welton, Professor Karl Pearson, Mr. Bertrand Russell, and Dr. McTaggart. After stating in turn the views of each, he proceeds to demolish them all with satirical impartiality. As regards such of these authors as are still living his criticisms are often cogent and sometimes appear unanswerable. But we do not think he fully appreciates the strength of the positions occupied by Hume and Mill, nor, indeed, by Mr Russell, with whose works Dr. Mercier does not seem to be so well acquainted as he is with those of his other victims. Dr. Mercier condemns all theories of causation which reduce it to the elementary factors of antecedence and consequence. There is something more, he thinks, in the relation of cause and effect than mere invariability of association or succession. He drags in the conception of "Power" in the cause, which compels the effect to follow. A cause, he holds, is something more than appears on the surface; it contains an active principle—though Dr. Mercier does not use the word—which renders the effect inevitable. In this conviction we may see an analogy with Dr. Mercier's views on vitalism. While in physiology he is prepared to believe that there is some "vital" agency which enters into the working of the organism and removes it from the sway of material and physical laws, so in logic he roundly affirms something of a metaphysical nature in the cause by which the effect is produced. The subject is thus linked up with wider philosophical tendencies, and agreement or disagreement with Dr. Mercier is likely to depend on the general school of thought to which the reader belongs.

After full discussion of the theory of the subject, Dr. Mercier comes to the practice. He illustrates the need for a clear and correct concept of cause by reference to the official publications on the causes of death and insanity. He has no difficulty in showing the extreme vagueness of these statistics, consequent upon inadequate definition of what is meant by cause. "The old legal maxim says that fraud lurks in generalities," and, as Dr. Mercier well adds, "to the uncritical it often seems that safety lies in generalities." He devotes an acute chapter to "Methods of Ascertaining Causes," and insists with truth that, if the rules there laid down were followed, the identification of many causes of insanity would be facilitated. Among the most interesting chapters in the book to the average reader are that dealing with "Errors in Attributing Causation," and the final chapter on "Belief." Throughout the work Dr. Mercier lightens and strengthens his arguments by a remarkable power of illustration and analogy. Though it cannot be anticipated that the book will give any satisfaction to orthodox logicians, yet it is one that they can scarcely pass by without some definite reply. At any rate, such silence would be fairly construed as a confession of weakness.

Notes on Military Orthopædics. By ROBERT JONES, C.B., F.R.C.S. Edin., &c., Colonel, A.M.S. London: Cassell and Co. 1917. Pp. 132. Price 2s. 6d. net.

As Sir Alfred Keogh remarks in his introductory note, the publication of this book is most opportune, and the long experience and reputation of the author its best recommendation. The volume, tersely but lucidly written, will be cordially received by military surgeons, who will find in it the practical application of orthopædic principles to the treatment of war injuries. In a few sections, each concerned with one of the main problems of military orthopædic surgery, a large amount of helpful instruction is imparted. The chapters dealing with the disabilities of the knee-joint and with bone-grafting are specially useful. Himself the champion of the manipulative school in the treatment of fractures, Sir Robert Jones emphasises the utility of efficient mechanical measures; when open operation is rendered absolutely necessary by the occurrence of faulty or deficient union he employs bone-grafting in lieu of plates and screws. He holds, by the way, that the latter methods require less surgical skill than does the carrying out of the technique of bone-grafts.

The omission of a special chapter dealing with the treatment of stiff joints by manipulation, or so-called bone-setting, is, perhaps, unfortunate, seeing how extensively these methods are at present being applied by orthopædic surgeons in military hospitals.



Traitement et Restauration des Lésions des Nerfs. By Mdme. ATHANASSIO-BENISTY. Paris: Masson et Cie. 1917. Pp. 179. Price 4 francs.

ISSUED as a sequel to the same author's "Formes Cliniques des Lésions des Nerfs," lately reviewed in this journal, this volume, with a preface by Professor Pierre Marie, is devoted to a full exposition of the methods of treatment of injured nerves and of the consequent paralyses, by surgical and mechanical means. A chapter is also given to the symptoms indicating serious injury to the nerves. Taken together the two volumes give an excellent account of the new knowledge of nerve injuries acquired during the present war.

New Inventions.

THE LUC QUARTZ GLASS SYRINGE.

WE have received from Messrs. Allen and Hanburys, Limited, Wigmore-street, W. 1, a glass syringe which possesses the practical merit of withstanding sudden and extreme change of temperature occasioned by any form of sterilisation. The instrument, of which we give an illustration, is called the *Luc* and is made of fused quartz glass, being so constructed that it is unnecessary to separate the parts before sterilisation. The complete syringe may be

placed in boiling water without fear of breakage, distilled water may be drawn up into it and boiled over a flame, or hot oil at a high temperature drawn up. The only precaution required is to withdraw the piston from the barrel into the metal container attached to it in order to prevent the glass barrel, which does not expand when heated, being broken by the expansion of the metal piston within it. The apparatus, its metal case, and a needle-holder can also be sterilised as a whole by dry heat, thus preventing any risk of rusting either the case or the needles. The price of the syringe varies, according to the size and accessories, from £1 10s. to £3.

THE LANCET.

LONDON: SATURDAY, JUNE 23, 1917.

The Treatment of Septic Wounds.

SIR ALMROTH WRIGHT possesses uncanny skill in investigating physiological processes, in devising ingenious experiments to discover the defensive powers of the body, and in initiating, on the conclusions which are drawn from these experiments, therapeutic measures new in direction and valuable in result. He has not contented himself with the work he has already done, and been busy merely with elaborating or perfecting it, as might be hastily assumed from his recapitulations; his labour has been progressive, the common direction of his energies being the obtaining of a perfect method of treatment of infected wounds. In the present number of THE LANCET he has set forth the conclusions at which he has arrived to-day; the basis of his address was delivered some weeks ago at the Royal Institution, since when he has had opportunities of adding to his message in numerous particulars.

The address is a piece of straightforward arguing, which deserves close reading. To appreciate fully the basis of fact on which Sir ALMROTH WRIGHT has founded his methods, we must recognise that the natural defensive power of the body against microbic invasion is twofold: it depends partly on the phagocytic action of the leucocytes and partly on the destructive action of the effused serum. The power possessed by the serum is of vast importance, and is closely associated with the power of normal blood serum to neutralise the digestive ferments and especially trypsin; and certain experiments, which are reported, indicate that it is this antitryptic action which enables the serum to inhibit the growth of septic micro-organisms. The phagocytic action of the leucocytes is a process whose significance has now passed into common pathological knowledge. But before the leucocytes can engage invading microbes they must have migrated from the capillaries. This preliminary action of resistance can be stimulated, for certain substances applied to the surface of a wound have the power of increasing this emigration, just as other substances can reduce the diapedesis to a minimum. For instance, a weak salt solution favours the migration of leucocytes, but a 5 per cent. solution of salt will reduce it greatly, while in the presence of gross sepsis the resisting movement is brought almost to a standstill. Another feature in this elaborate physiological process is brought to attention by Sir ALMROTH WRIGHT. Septic wounds can be divided into what he terms "live spaces" and "dead spaces." In a live space the tissues are well supplied with blood; there is an abundant flow of antibacterial lymph and the terrain is suitable for phagocytic action. In a dead space the tissues have been bruised and cut off from their blood-supply, so that the serum and the leucocytes can only act in their different ways at a serious disadvantage. The infection quickly spreads into neighbouring tissues, toxins are absorbed, and the patient has septic fever. An abscess cavity is, of course, the typical dead space. The application of knowledge of this kind, gained by laboratory experiment, to the treatment of septic wounds follows clearly enough, whether we are dealing with old-established principles or a new technique. The first point in the treatment of an infected dead space must be drainage, and every portion of a wound which would, if left to itself, become a dead space must be laid open. Then comes the treatment of the infected walls, and with regard to the extent of infection we have to remember, and remember always, the conditions of war. Often it must happen that hours or days elapse before the wound comes under the surgeon's hand. An infected wound if left to itself grows dry, in which case the capillary circulation will cease and there will be no outflow of bactericidal lymph, while there will be an enormous increase in the growth of septic organisms; thus sloughs are formed and the sepsis tends to spread. This drying process will go on during the transport of the wounded if no salutary interference is forthcoming. But should the wound be simply kept moist there will follow a great increase in the number of microbes, the leucocytes poured out will die, and the tryptic ferment set free will exert an erosive action on the walls. Again the infection tends to spread. What shall be done, then, to wounds during transport when they cannot be dressed? Sir ALMROTH WRIGHT answers this question with an illuminating account of the investigation into the action of antiseptics in living tissues. He shows that the influence of an antiseptic applied to the interior of a wound is bound, in ordinary circumstances, to be superficial, and that frequent re-application of an antiseptic during transport will fail of the desired effect; whereas the employment of a suitable hypertonic solution will favour the outflow of lymph and so drive back the invading microbes. The routine of treatment at the hospital, which all these researches lead up to, is no new thing. The wound has to be made clean, and this can be accomplished by thorough drainage and the use of hypertonic salt solution, which both assists to remove dead tissues by a process of cleansing digestion, and at the same time causes an increased flow of lymph to combat the infection itself.

Sir ALMROTH WRIGHT'S address closes with an instructive discussion of the use of Dakin's solution and of the Carrel method. So far as Dakin's solution is concerned, the conclusion is reached that it has little antiseptic power, which is quickly lost by evaporation, and then its action is physiological, and the outpouring of lymph and leucocytes goes on. With regard to the Carrel method, Sir ALMROTH WRIGHT argues that it cannot act by completely sterilising the wound; but he regards the procedure as of extreme value, for it furnishes

a new and improved technique for physiological treatment of an infected wound, while he considers that its success depends very little on the antiseptic action of Dakin's fluid. The author has spared neither pains nor time in the investigation of a very difficult and important subject, and the address must be read closely, if the basis of the arguments is to be fully realised.

Depopulation and the Endowment of Motherhood.

THE smallness of the birth-rate in France is a familiar topic to which the war has added a new and poignant interest. In the *Revue d'Hygiène* for April–May, 1917, appears the report of a small commission on depopulation in France, regarded from a physiologico-medical point of view, presented by Professor CHARLES RICHET to the Academy of Medicine. The facts are well known, but bear repetition in the striking form in which Professor RICHET presents them. The annual number of births, which in 1876 slightly exceeded 1,000,000, had fallen in 1913 to a little over 745,000, and the proportion per 10,000 of population from 210 in 1910 to 172 in 1911. As is usual with a low birth-rate, infant mortality also stands at a low figure, but, as Professor RICHET points out, no decrease in the infant mortality rate can compensate for such a fall in the birth-rate. While at the end of the first year of life in Russia, for example, taking the birth-rate at 465 per 10,000 inhabitants, against one of 200 in France, the 465 babies might have been reduced to 372, a larger proportion of the 200 French babies would survive, and yet the total number not exceed 180. The low birth-rate is present in all sections of the community, urban and rural, rich and poor, worker and intellectual alike. The drop is, in fact, common to all European nations, but greater in France than elsewhere. Taking the birth-rate in each country for the decade 1841–50 as the standard and calling it 100, the rate in the decade 1901–11 was only 74 in France, compared with 84 in England and Sweden, 89 in Austria-Hungary, and 92 in Germany. For every additional Frenchman per year there were 70 Russians and 200 Europeans. In France it would take 370 years to double the population, whilst in Germany a century would see the number of inhabitants trebled.

Whilst many causes such as the emigration into towns, alcoholism, the effect of the civil code and of increasing irreligion have been called in to account for some share at least in the diminution, the prime cause is undoubtedly, Professor RICHET assured his hearers, the sterility or, more correctly, the non-fecundity of marriages, 15 per cent. of which are absolutely sterile, the remaining 85 per cent. of parents limiting the number of their offspring to an agreed figure. Certain districts of Paris of a higher social class have a still smaller birth-rate than more populous parts of the city, but there is no doubt that all classes have adopted neo-Malthusianism as their family religion. In 1891 a family with seven children or more was a rarity in Paris (1·3 per cent. of the total number of families), and even in the country the proportion in the last Census year (1911) did not exceed 3 per cent. Professor RICHET'S Commission holds that argument is likely to be fruitless, inasmuch as the smallness of the family in France is a question of economy and foresight. A child up to the age of 15 years costs the family exchequer at least 400 francs per annum, representing one-sixth part of the average paternal earnings. Three children would account for half the income, and are therefore the extreme limit for the prudent wage-earner. The only practical remedy, states the Commission, is the endowment of motherhood by an allocation commencing from the moment that pregnancy becomes certain and lasting to the end of the first infancy, a period defined by the eruption of the twentieth tooth. The Commission holds, indeed, that families with no or few children should pay for those who have many, and regards 2000 francs a head as a very moderate price for the country to pay for a potential Frenchman.

We began by saying that the fact of the decreasing birth-rate was well known in France. It is also well known in this country. But opinion on this side of the Channel is widely divergent on the best way of dealing with the relative depopulation. Professor RICHET'S solution was evidently acceptable to a majority of his hearers at the Academy of Medicine, who are said to have warmly applauded his concluding remarks. In the discussion which followed it was left to a single speaker, M. BARRIÉ, to query where the revenue was to be found to provide for the endowment of motherhood. But the idea of a State subsidy for large families and of State assistance for the young children of widows is no new one in France, and is leading on there, as it has done in America, to the provision of child pensions as a matter of ordinary State policy. Judge HENRY NEIL, of Chicago, who is now in this country on a mission to popularise what is practically an endowment of motherhood, states that pensions to widows with young families to bring up are already given in 27 out of the 48 States, one State at least granting them—as Professor RICHET also proposes to do—to mothers irrespective of their civil state. In the States where the provision is in force the maintenance is granted in respect of all children under 14 years of age, ranging from 7½ to 10 dollars a month for each child. An advocate of the scheme points out that whereas it costs a hundred dollars a year to support an orphan by the pensions system, it has cost the State an average of three hundred dollars a year to support a child in an institution. The war is familiarising the whole civilised world with the notion of endowing motherhood in one form or another, and more is likely to be heard of it.

THE NATIONAL BABY WEEK.—A "Richard Burbidge Fund" will be opened at Harrod's Stores on July 2nd, and during the National Baby Week it will welcome every offering, however small. The late Sir Richard Burbidge was the chairman of the Finance Committee of the movement and the fund is intended to memorialise his interest in the work.

Annotations.

"Ne quid nimis."

THE CROONIAN LECTURES.

IN the second Croonian lecture[1] at the Royal College of Physicians of London Colonel J. G. Adami dealt with the difficult subject of adaptation in bacteria, and the consequent evolution of disease. After indicating the absurdity of thinking that the infectious diseases now known to us have afflicted man from his first appearance on the planet, he pointed out that if bacteria have been present from the beginning of the world, this would not imply that the specific infections have been in existence for the same period, for zymotic phenomena must run parallel with geological, which teach differently. The reason why we cannot recognise the descriptions of epidemics given by classical authors is not necessarily that they were incapable of noting characteristic symptoms; more probably they described conditions no longer existing. It is known that in more recent times infections have come and gone. The tritest example is the sudor anglicus, or "sweating sickness," but many diseases have made their appearance in comparatively recent times—e.g., diphtheria, cholera, syphilis. Here Colonel Adami warned his audience that a second principle may have to be considered. Certain of these diseases may have been present for an indefinite period endemic in a particular locality, and then with the opening up of trade routes have spread rapidly. Admitting this, the conclusions reached by a study of the geographical distribution of animals and plants must also be admitted—i.e., where a species (such as the rabbit or sparrow) when introduced into another continent shows an immediate spread—the fact that it was not there before forms an indication that the spread had arisen at a period subsequent to the separation of one continent from another. Whichever side was taken in the syphilis controversy, said Colonel Adami, it had to be confessed that this disease was non-existent in early Egypt or in the Rome of the time of Galen.

The Croonian lecturer's picture of the evolution of an infection is very interesting:—

"If every infection is due to the diffusion through the body of the toxins of one or other particular species of micro-organism, it deserves note that pathogenic microbes do not form an order by themselves, but, on the contrary, are singularly diverse in their affiliations. With scarce an exception every genus of micro-organism has its representatives among the pathogenic microbes, or, conversely, every pathogenic microbe has closely related forms differing from it in little beyond the fact that the one is virulent, growing in or upon the tissues, the other non-virulent. Next, these closely allied species are found suggestively either growing in the cavities and on the mucous surfaces of the body, or in the water and foodstuffs taken up by the individual. This state of affairs in itself strongly indicates that at some period or other pathogenic microbes have originated from those saprophytic on the body surfaces or existing in the foodstuffs. This natural deduction has been opposed notably by the German school of bacteriologists, with the late Robert Koch at their head, who stood out for the fixity of bacterial species."

In studying bacteria two apparently opposite and contradictory facts are to be made out: on the one hand they are extraordinarily conservative, but on the other there are certain changes of environment which lead to certain and definite modifications in the properties of bacteria, the orders of variation being usually given as three—fluctuations, mutations, and impressed variations or modifications. Colonel Adami brought evidence forward to show that in the bacteria at least what are usually considered as mutations, or chance variations, are in truth impressed variations due to specific alterations in environment. Whereas under the ordinary conditions of experiment certain members only of a bacterial colony take on the property of fermenting a foreign or new foodstuff, this condition of experiment can be so altered that all the members of the colony with absolute precision can be made to acquire this new property. The experiment can be so arranged as to demonstrate that here is no question of chance variation, of the survival of those forms, and those forms alone, which have exhibited variation in a favourable direction—no question, that is, of survival of the fittest—but that there is, within certain limits, direct adaptation in the Spencerian sense, direct equilibration between the organism and its environment. Certain experiments recently conducted by Major F. B. Bowman, C.A.M.C., with the typhoid bacillus, proving this point, were given in detail, and similarly, as an example of variation by loss of factors, there is the classical experiment, ever quoted, of Pasteur and his lieutenants, Roux and Chamberland, in which by exposing any culture of the anthrax bacillus over a given period to a given temperature of growth with absolute precision the power of the spore production is lost, and now for years—and thousands of bacterial generations—grown under ordinary conditions spore production does not manifest itself. Now if this be true of other properties, it must be true regarding virulence, and we have methods by which we can exalt or depress the virulence and pathogenic properties of bacteria, while we can take harmless non-pathogenic bacteria and with absolute precision, and not by chance variations, convert these into highly pathogenic virulent forms. It is this direct adaptation, evidently, that explains the origin of the infections.

[1] A summary of the first Croonian lecture was published in THE LANCET of June 16th (p. 921).

INCIDENCE OF INFECTIOUS DISEASE IN 1916.

THE report of the Medical Officer of the Local Government Board on the incidence of notifiable infectious disease during the year 1916 has now been published and contains, as always, much information of vital interest as to public health. As in previous years, the rates of infectious sickness in each thousand of the several populations are given in the local tables for 1916. The returns indicate that a considerable proportion of the cases were imported from abroad, having been notified at the seaports, which are therefore especially exposed to danger. In England and Wales only 4 cases of typhus fever were reported last year, as compared with 45 in the year preceding. Scarlet fever was notified in 75,722 instances, or fewer by 51,364 than in 1915; diphtheria in 51,707 instances, or 1890 fewer than in the preceding year; enteric fever in 5564 cases, as compared with 6364 in 1915 (in 17 instances paratyphoid was specifically mentioned). 1996 cases of puerperal fever were notified, against 2057 in 1915; 18,520 cases of erysipelas, as compared with 23,382; 1306 cases of cerebro-spinal fever, against 2566

in 1915; 689 cases of acute poliomyelitis, against 517 in 1915. Small-pox was reported, sometimes erroneously, in 149 instances last year, 55 of them being notified from places connected with seaports. The cases reported in 1916 were more by 59 than those reported in 1915. It will be noted that, with the exception of the two last, all the principal infectious diseases are reported to have been less prevalent in 1916 than in the year immediately preceding. Since 1911 the incidence of pulmonary tuberculosis has been notifiable throughout the country. In terms of population the disease was apparently observed during 1916 in the case of 2·10 per 1000 living, or somewhat more than in the preceding year. The reported cases, however, include a considerable number of duplicate notifications—a fact which must be taken into account in interpreting these rates. The rate was equal to 3·19 per 1000 of the population in London, and to 1·96 per 1000 in extra-metropolitan England.

THE FACTORS OF CARDIAC IRRITABILITY.

Dr. J. Strickland Goodall's Chadwick lecture on the Soldier's Heart, being based on the critical analysis of 2250 cases, and not on mere *obiter dicta*, is worthy of careful consideration. He starts from the postulate that since the heart is composed of both nervous and muscular elements it may become over-excitable as regards either component. Nervous irritability is usually characterised by increased rate, while the rhythm may or may not be affected. He classifies the nervous irritable heart into three groups. The first is the emotional, susceptible, or unstable heart. It is essentially physiological, but reacts violently and excessively to every emotion, such reaction being aggravated by overwork, alcohol, tobacco, and anything which impairs nerve control or injures the general health. The second is the youthful or fretful heart, which "speeds up" during inspiration and slows down during expiration. It is entirely physiological, and should not be regarded as a bar to active service. The third type is where there is tachycardia, either permanently, as in Graves's disease, or periodically, as in paroxysmal tachycardia. He believes that in persistent tachycardia fright or other emotion causes the suprarenal to pour adrenalin into the circulation, and the thyroid exerts itself to neutralise this. The over-action of the suprarenal is temporary, but the thyroid continues to over-act. He regards the first and third of these types as only fit for sedentary or light military duties. Irritability of the heart muscle is indicated by a definite but variable irregularity of the pulse. He believes that the irritable heart of the soldier falls into this category, and that it is begotten by overwork and under-rest. X ray examination shows that hearts which exhibit a persistent over-excitability either of muscle or nerve are too horizontal in position because they are too soft, so that they lie more or less on the diaphragm and may be deformed by distension of the stomach. This horizontal type is found in old age, in sedentary workers who take too little exercise and are often the victims of a chronic toxæmia, after infective conditions, and after long-continued overwork or mental strain with insufficient rest. The tone of any organ depends primarily on two factors, the integrity of the nervous control of the organ and systematic use followed by adequate rest. Lack of tone arises from impaired nervous control, habitual overwork with insufficient rest, or disuse, insufficient use, or misuse. An exhausted tissue or organ is also over-excitable, and hence we find that with atonia there is over-excitability. The whole heart may suffer in this way, or the change may be confined to the auricles or to either ventricle. The right ventricle is affected mainly by overstrain, the left by arterio-sclerosis. Auricular over-excitability is much commoner in soldiers than in civilians, and Dr. Goodall is of opinion that it is a more serious condition than ventricular over-excitability, as it usually passes into some graver condition, such as auricular flutter or fibrillation.

PUBLIC HEALTH WORK FOR WOMEN.

PUBLIC health work affords to-day good openings to well-educated women who have qualified by training. Women can thus equip themselves to become sanitary inspectors, health visitors, superintendents of schools for mothers and similar institutions, relieving officers, lady almoners, lecturers and teachers giving instruction in matters connected with sanitation and health, secretaries to local health societies, and officers in connexion with the carrying out of the National Insurance Acts and the Poor-law. Vacancies in such positions are increasing in number and variety, and although they may not offer all the opportunities that the medical profession holds out to clever and ambitious women, yet they have the compensating advantage of not necessitating a long, exacting, and costly education. A course of instruction is offered by the National Health Society under which a training of from four to six months is given, with a view to fitting students for the posts enumerated, the period of subsequent training necessarily varying in accordance with the intentions of the student. The National Society, in fact, offers itself as an organisation prepared to help its associates, and women generally, by advice in the selection of a particular career, and to provide, so far as it can, teaching, encouragement, and assistance in the obtaining of posts. Miss Fay Ray Lankester, the secretary of the National Health Society, 53, Berners-street, London, W. 1, invites communication with her from women who are desirous of helping their country and themselves by undertaking useful work.

NEURASTHENIA IN SOLDIERS.

LECTURING at the Royal Institute of Public Health on June 13th, Sir John Collie stated the predisposing causes of neurasthenia in soldiers to be the fear of being afraid, want of sleep, and the terrifying experiences. The emotional suppression cultivated by every good soldier added its quota to the state of anxiety predisposing to war-strain. He distinguished three types of neurasthenia: the first stage of mere asthenia or weakness; the more advanced cases with well-marked tremor, extreme nervousness, and loss of weight; and a hypochondriacal class whose self-control had always been subnormal, and unfitted by temperament to be soldiers. In the treatment of the neurasthenic the whole environment should be one of cheerfulness and hope, combined with confident reassurance of complete recovery. Many of these cases, Sir John Collie said, were now treated immediately behind the firing line, where the early application of psycho-therapeutic methods had been signally successful in cutting short attacks. Each

army now had its special shock hospital staffed by selected medical officers. A Special Medical Board for Nervous Disorders, of which he was president, dealt with men discharged for neurasthenia, re-examining them after leaving the service from time to time. This board was in close touch with the local War Pensions Committees throughout the country, and assisted men to obtain work in civil life. Several large proprietors had agreed to employ men recovering from the effects of shell shock on the land, and arrangements were being made to form camps in country districts where the men would be housed during the summer months. The first Home of Recovery had been provided at Golders Green by the British Red Cross Society and the Ministry of Pensions. The Ministry of Pensions had arranged for intensive French culture to be a feature of the outdoor training of the men, a pursuit which, with its comparatively light work, should be specially suitable for large numbers of men suffering from functional nerve disease.

INDUSTRIAL ACCIDENT MORTALITY IN AMERICA.

THE increased insecurity of life during the European War made itself felt in America during 1916 and is seen in the mortality statistics compiled by the Metropolitan Life Insurance Company for their 9,000,000 white policy-holders. The accident rate for the working classes of the United States in 1916 was found to have increased five points per 100,000 living over the rate for 1915, in contrast with the tendency in recent years toward a reduction in the fatal accident rate. The total rate of 73·5 (68·9) included traumatism by fall, 13·7 (12·4); accidental drowning, 9·5 (11·9); traumatism by automobiles, 8·8 (5·7); burns, 8·4 (8·1); traumatism by steam railroads, 7·6 (7·3); and other less frequent causes. The figures in brackets are the corresponding rate for 1915. Accidental drowning alone shows a decrease, chiefly due to the inclusion in 1915 of the deaths in the Eastland disaster. Mortality from automobile accidents and injuries showed by far the largest increase, being responsible indeed for three-fifths of the increase in the total accident rate in 1916. The company attributes the general rise to increased activity in industry and the speeding-up incident to war conditions. It is instructive to see this result proved by figures for a non-combatant country. Probably in every country of the world 1916 was a less safe year to live in.

THE WORK OF ASYLUMS IN EGYPT.

THE official report for the year 1916 of the Lunacy Division of the Ministry of the Interior, Egypt, gives welcome evidence of the steady advance which is being made in lunacy administration in Egypt. Much of the non-medical work has now been taken over by the General Board of Administration, relieving the heads of asylums of an enormous burden and setting them free for their special work. Again this year, as is usually the case, there is an excess of applicants over available accommodation. The two asylums together provide room for 1550 patients, and of the 1516 lunatics notified 970 were admitted, while 575 patients were sent back to their friends uncured but supposed to be harmless. Besides these, 324 British soldiers were treated by Dr. J. Warnock in a small special hospital. Although in itself one man's work, the Criminal Lunacy Department has also fallen to Dr. Warnock, who has tabulated the forms of insanity associated with various forms of crime as well as the special causes contributing to the criminal lunacy. Among the latter pellagra plays a very important part in Egypt; haschish is also a common cause. Careful examination of the Wassermann reaction revealed the frequent presence of syphilis, not alone in cases of general paralysis, but in many other forms of mental disorder. A number of patients were received as voluntary boarders, a gratifying recognition of the nature of mental disorder among native Egyptians. The death-rate was 11·2 per cent. of the average asylum population. Pathological study was carried on in the asylums notwithstanding the war, and dealt chiefly with ankylostoma, malaria, and bilharzia. The associated asylum of Khanka, under the direction of Dr. H. W. Dudgeon, employs many patients on the land, who provide vegetables for both institutions. The report gives evidence of the untiring service of the responsible authorities, of which the award to Dr. Warnock of a New Year honour was a timely recognition.

A STANDARD OF CLEANLINESS.

IN a pamphlet dealing with uncleanliness among elementary school children, reprinted from *School Hygiene* for February last, Dr. A. H. Hogarth, medical officer of health for Buckinghamshire, laments the inability of many school medical officers to understand the elementary principles underlying statistical calculations, and states that no accurate representation apparently exists of the extent of uncleanliness among school children. He mentions the common grounds of statistical fallacy, enunciating four requirements which must be satisfied in examining children for the purpose in view, viz., non-selection, non-preparation, accuracy of examination, and the statement of a standard of cleanliness. For his own county he has adopted a classification into seven groups, each capable of precise definition, starting from (1) clean, through (2) nearly clean—that is, hair not containing more than 10 or 12 nits, or a head, face, and neck in need of washing—and (3), (4) nits only, counted by tens or by hundreds, to (5) few nits plus one or more lice, (6) many nits plus lice, and (7) a dirty and neglected child whose home is to be visited by the N.S.P.C.C. He gives percentage tables of inspections during the years 1912–15, in which at a first inspection the number of clean children progressively increased from year to year, the figures in boys being 75, 85, 94, 96, and in girls 40, 58, 75, 81. Surprise visits are paid by the medical officer to the worst schools reported by the nurses with a view to searching out the persistent offenders and taking them to the police courts. This policy has made itself felt in every parish of Buckinghamshire, there being no subsidiary court which has not tried a batch of such cases, and no local newspaper which has not faithfully reported them. Between January, 1912, and December, 1915, 313 parents were summoned on account of 352 children, and 284 parents were fined from 1*s.* to 10*s.* each. The committee's practice of keeping an exact record of the numbers of nits or lice found at each examination by the nurse has proved most useful in obtaining convictions in court. Statistical accuracy has been more than its own reward.

THE office of the Ministry of Pensions has been removed from Great George-street to Westminster House, Millbank, S.W. 1.

"Audi alteram partem."

WAR EMERGENCY FUND OF THE ROYAL MEDICAL BENEVOLENT FUND.

To the Editor of THE LANCET.

SIR,—We beg to support the urgent letter of appeal to this Fund which appeared in last week's medical journals. This Fund was instituted by the Royal Medical Benevolent Fund last year to afford assistance to members of the profession who, in consequence of having joined the Army Medical Service, find themselves in temporary difficulties.

We very strongly commend the claims of this Fund to the generous support of both the profession and the public.

We are, Sir, yours faithfully,

FREDERICK TAYLOR, President, Royal College of Physicians.
W. WATSON CHEYNE, President, Royal College of Surgeons.
W. H. NORMAN, Surgeon-General, R.N.,
Director-General of the Medical Department of the Navy.
ALFRED H. KEOGH, Director General, Army Medical Service.
WILLIAM OSLER,
Regius Professor of Medicine, University of Oxford.
THOMAS CLIFFORD ALLBUTT,
Regius Professor of Physic, University of Cambridge.
JOHN TWEEDY,
Late President, Royal Medical Benevolent Fund.

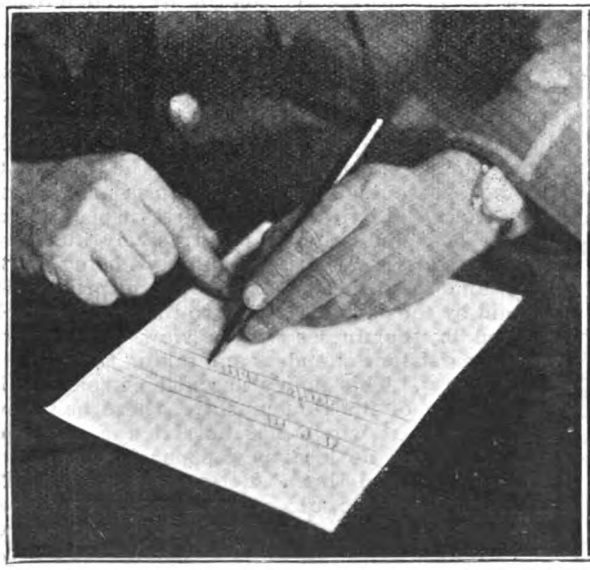
11, Chandos-street, Cavendish-square, W. 1, June 16th, 1917.

*** We publish elsewhere the details of certain cases which have already been relieved by the War Emergency Fund.—ED. L.

EDUCATION OF THE LEFT HAND OF DISABLED SAILORS AND SOLDIERS.

To the Editor of THE LANCET.

SIR,—Under the above heading Dr. C. W. Hutt records, in THE LANCET of April 7th (p. 553), the method used by M. Tamenne for teaching writing with the left hand to men who have lost their right hand. The results achieved are undoubtedly satisfactory, but it will be found that it is infinitely easier to write in exactly the opposite manner, and the reasons will be appreciated when explained.



Firstly, instead of the line of the writing sloping up towards the right shoulder as shown in the article of April 7th, the line should be at an angle of about 50° with the edge of the desk towards the right ↘. At the same time the slope of the writing should be backwards at about 45° to the writing line, at least to commence with. In this method it will be found that the fingers are in the most natural position for writing, the arm and wrist being in a straight line, and there being a wide sweeping movement of the wrist if required. It will be found, and can be seen every day with those trying to teach themselves to write with the left hand, that to write straight across the paper—i.e., parallel to the edge of the table—leads to a most cramped position and to great limitation in the movement of the wrist, and that a great deal of the movement across the sheet has to be made with the upper arm.

This difficulty M. Tamenne has experienced, and following his rule (5) "always take care that the hand is immediately below the point where he is writing," he states, "the man will find this difficult to carry out and the effort to do so will tire his hand." Precisely so, because the position is cramped and unnatural. My method I have demonstrated to the men coming before a Medical Board here, and they unanimously declare that it is much easier than the "straight across" method which they try for themselves. If anyone will try the two methods for himself for a short time he will see the difference. I endorse emphatically the importance of not attempting to get on too fast. Also it makes an enormous difference if the teacher can write left-handed. The importance of this I found some years ago, when I was responsible for a boy of 13 who had a right-sided birth palsy. Several schools had vainly tried to teach him to write with his left hand and the result was lamentable. I found that the reason was that his damaged brain could not translate to his left hand the motions shown him by his tutor's right hand. The only remedy was to learn to write with one's left hand, so that he could copy the movements. This I did with an entirely satisfactory result, as he easily copied the movements he saw. The idea of slanting the writing I got from watching a left-handed clerk many years ago.

There is one thing that is important, not to start the men with a broad pen, or they are apt to make blots owing to the reverse way the pen is held as compared with the writing. A fine fountain pen I find the easiest to use.

The reverse print (photograph B) shows how exactly similar the position I describe is to the correct right hand method. Later on, as in ordinary writing, the slope can become more upright; but I am convinced that it is easier to commence in the manner shown.

A

B

The photograph A shows the position of the hand and paper when writing with the left hand. Photograph B is a reverse print from the same negative, showing similarity of position to correct right hand method.

I am, Sir, yours faithfully,

ELWIN H. NASH, Major R.A.M.C.

The Lord Derby War Hospital, Warrington.

THE LUMLEIAN LECTURES AND MEDICAL RESEARCH.

To the Editor of THE LANCET.

SIR,—I was much interested in Professor A. R. Cushny's paper on Digitalis in Auricular Fibrillation in your issue of June 9th, especially in view of the recent correspondence in your columns on the Lumleian lectures. Up to the present it has been assumed that the beneficial action of digitalis in auricular fibrillation is due to the blocking of impulses from auricle to ventricle through stimulation of the inhibitory mechanism of the vagus. But Professor Cushny states in his paper—

> That in a number of observations which I made in Mackenzie's wards with Marris and Silberberg we satisfied ourselves that in auricular fibrillation the change in conduction is not inhibitory in nature, for it is not prevented by complete paralysis of the vagus by atropine.

Later on he says—

> We have two types of digitalis action on the heart. ..... The second or anomalous reaction occurs in the auricular fibrillation in man and not in that experimentally induced in animals; here the *heart is slowed by direct action on the muscle* independently of the normal inhibitory mechanism.

In his final paragraph Professor Cushny says—

> Another result of digitalis on the animal heart *is the increase in the strength of contraction.* Does this play no part in the improved efficiency of the heart?

Since the advent of electro-cardiography it seems to me that the neurogenic doctrine has been exalted to a position of undue importance, more especially in relation to so-called auricular fibrillation. The irregularity of rhythm in the ventricle in auricular fibrillation is attributed, as far as I am aware without any sufficient evidence, to the irregular transmission of feeble, incoördinate stimuli from the flickering fibres of the fibrillating auricle, which one would not suppose capable of exciting a contraction in the ventricle. But even admitting this, how can the mere cutting off of a few nervous impulses from auricle to ventricle by itself restore the functional efficiency of a heart muscle that has broken down under stress? Yet that has been the explanation given of the action of digitalis in these cases. It is a great satisfaction, therefore, to find that so distinguished an authority as Professor Cushny has now raised the question as to whether it is not after all increase in the strength of the contraction of the cardiac muscle induced by digitalis, which plays an important part in improving the efficiency of the heart. It is not merely in auricular fibrillation that digitalis is of value. Any clinician knows the extraordinarily satisfactory results obtained from the administration of digitalis in cases of heart failure and dropsy associated with mitral incompetence, even when the pulse is quite regular and there is no question of "auricular fibrillation." Surely the beneficial effect in these cases is due to the action of digitalis in improving the tonicity of the cardiac muscle, so that the dilatation is reduced, the force of the beat improved, and the quantity of residual blood diminished.

In mitral stenosis, whatever may be the case in the valvular lesions, the heart is working at a great mechanical disadvantage. The left ventricle is small, imperfectly supplied with blood, and has comparatively little work to do. The right ventricle hypertrophies on account of the extra work imposed by the steady increase of pressure in the pulmonary circulation due to the narrow nozzle at the distal end in the form of the stenosed mitral orifice. The pressure in the left auricle is also greatly raised and is an important factor in maintaining as rapid a flow of blood as possible through the narrow orifice during diastole. When the right ventricle fails, the pressure in the left ventricle falls and the supply of blood to the left ventricle becomes even more insufficient and irregular. The beneficial action of digitalis in such a case may well be explained by its effect in restoring the tonicity and efficient action of the right ventricle, which is the important factor in maintaining a working circulation. A time must come, however, in severe cases of mitral stenosis at which the almost impassable barrier of the button-hole mitral orifice causes a complete breakdown of the right ventricle, and neither digitalis nor any other drug is of any use in averting the final catastrophe.

To take another point. How is it that digitalis, which has such a beneficial effect in auricular fibrillation, is of no service in paroxysmal tachycardia, Graves's disease, or, indeed, in any other form of tachycardia? If it can arrest impulses from auricle to ventricle with beneficial results, as is postulated in auricular fibrillation, why does it fail in the latter group?

The modern conception of heart failure seems to ignore the important fact that there is a right and a left side of the heart, and that we may have failure either of the right or left ventricle, not necessarily of both. In mitral disease the stress falls on the right ventricle, in Bright's disease or high tension in the peripheral circulation on the left ventricle. In the former we get right heart failure eventually, in the latter left heart failure if the patient survives other accidents. In each instance the ventricle, which has most work to do, hypertrophies to meet the extra strain, and digitalis when administered will naturally have its preponderating effect on the side which has the larger mass of muscle.

The inhibitory mechanism of the vagus on the heart has been described as analogous to reins in the hands of a skilled driver controlling a regularly trotting horse. If the horse is exhausted and nearly dead-beat no amount of pulling on the reins will help him on his way; what he needs is a powerful pick-me-up. In the pathological conditions of the heart to which I have alluded above, digitalis, if I may so interpret Professor Cushny's results, appears to act as a direct pick-me-up for the exhausted heart muscle rather than as a stimulus to the inhibitory mechanism of the vagus. This is what we might expect from Nature's common-sense methods.

There are many other questions of interest raised by Sir R. Douglas Powell, Dr. Colbeck, and Dr. Alexander Morison in their letters to THE LANCET of June 9th and 16th, amongst them the question of back pressure and the significance of cardiac murmurs. The disastrous effects of back pressure on the lungs in mitral stenosis are so self-evident, both from the pathological and clinical standpoints, that I do not think it is necessary to dwell on them. As regards the significance of murmurs, every clinician knows that the presence of a mitral systolic murmur in itself may be of little importance; what really matters is the degree in which the functional capacity of the heart is impaired, and this one can easily judge by the response of the heart to increased work on exertion and whether or no cardiac symptoms are readily induced thereby. But one cannot afford to ignore the grave effects in mitral stenosis or aortic lesions of any serious degree on the hydraulics of circulation and the mechanical embarrassment of the heart entailed thereby, apart from other considerations.

That work of the greatest importance has been done by Sir James Mackenzie by his polygraphic tracings and by Lewis with the electrocardiograph in elucidating the problems of heart-block, extra-systole, and sinus arrhythmia I should be the first to admit, but for the reasons given above I am unable to accept in its entirety the doctrine of auricular fibrillation.—I am, Sir, yours faithfully,

JOHN F. H. BROADBENT.

Seymour-street, W., June 18th, 1917.

THE USE OF POLYVALENT VACCINES IN DYSENTERY.

To the Editor of THE LANCET.

SIR,—As a result of the investigations of Dr. J. H. Harvey Pirie on the bacilli causing dysentery in African natives in the Carrier Corps depôt at Nairobi, it was decided to try the effect of a polyvalent vaccine as a therapeutic measure. From the literature available it appeared that the drawback to antidysenteric vaccines was their extremely toxic character. It was thought that possibly the heat used to sterilise the vaccines might be in some way a cause of this toxicity and it was decided to try to prepare a vaccine sterilised by antiseptics alone.

The first antiseptic tried was eusol, but, although the solution was freshly prepared, it was found that it failed to sterilise the cultures, even when added in large doses. Recourse was then had to 0·4 per cent. carbolic acid, the antiseptic employed in this laboratory in the preparation of autogenous vaccines. It was found that the addition of this strength of carbolic acid brought about complete sterilisation in about two days.

Dr. Pirie selected from his stock of local strains a Shiga bacillus and bacillus of the Morgan type. These were incubated in peptone broth for 48 hours at 37° C. The cultures were then carbolised and tested for sterility after 48 hours. The vaccine was administered to Africans

suffering from dysentery at the Carrier Depôt Hospital, Nairobi, and it was found to cause no toxic symptoms. The treatment was begun on Sept. 1st, 1916, and since then 350 cases have been treated or are under treatment at the time of writing. The results have been most promising, and at a later date it is proposed to publish complete statistics. The majority of cases respond immediately, and others which do not show much marked improvement are often complicated by bilharziasis.

The vaccine has since had a bacillus of the type Flexner added, with improved results. It now consists of six different strains in the following proportions: *B. Shiga*, 1 part; bacillus resembling *B. Shiga* in all its sugar reactions, but motile, 1 part; bacillus of the *B. Flexner* type, 1 part; three different strains of the *B. Morgan* type, 3 parts. The cultures are made in flasks of peptone broth and grown for three days at 37° C. They are then carbolised, tested for sterility after two days, mixed in the above proportions and issued as required.

Therapeutic inoculation was first attempted with a dose of 5,000,000 *B. Shiga* and 5,000,000 of mixed strains of *B. Morgan* type, increasing by 5,000,000 daily, but it was found that more satisfactory results were obtained with large doses at longer intervals. The usual dose at present is 1 c.c. of the vaccine, made in the manner and proportions described above, on the day of admission. On the eighth day 2 c.c. are injected subcutaneously; on the fifteenth day 3 c.c. and, if necessary, on the twenty-second day 4 c.c. Still larger doses are being tried at the time of writing, but it is too early yet to form an opinion as to whether these bigger doses are advisable or not.

In addition to the use of the vaccine as a therapeutic measure African porters passing through Nairobi Depôt are being submitted to prophylactic inoculation. Unfortunately, so far no figures are available to show whether this inoculation is of any value or not.

We are, Sir, yours faithfully,

PHILIP H. ROSS,
Director of Laboratories, British East Africa; Honorary Adviser to the Director of Medical Services, E.A.F.

W. H. KAUNTZE,
Captain, West African Medical Staff (attached East African Medical Service).

THE POPULATION OF ASYLUMS FOR THE INSANE.

To the Editor of THE LANCET.

SIR,—For some time past the *Daily Graphic* has been publishing articles vituperating public asylums and all connected with them. On June 13th this newspaper prints a long article entitled "Heroes in Asylums." Nearly one-half of this is taken up with the correspondence of a person who writes: "I have been detained by the Lunacy Commissioners ever since December, 1905, as a lunatic." Further on it states that a patient was visited by a *Daily Graphic* representative, who we must suppose is an expert, and who could find nothing the matter except "twitching of the nerves (*sic*) and a highly strung manner which is typical of nervous patients." This kind of nonsense has been read by many and if no reply is made the public naturally say that "silence is consent." Writing to the *Daily Graphic* has been tried, but the letter was not inserted. I am writing therefore to crave the indulgence of your columns and to state that the article in question contains numerous inaccuracies, to put it as mildly as possible. This information is not needed by your readers, but I am hoping that through the instrumentality of medical men the public may learn where the truth lies. In the *Times* on the same day a coroner is reported to have stated that it was a scandal that so many insane patients were discharged from asylums.

I am, Sir, yours faithfully,

R. H. STEEN.

City of London Mental Hospital, near Dartford, Kent, June 15th, 1917.

IRISH MEDICAL ASSOCIATION.—The annual general meeting of this association was held on June 14th, Dr. R. Marlay Blake presiding. Some discussion took place with reference to the Midwives Bill for Ireland which has been drafted by the Local Government Board, and the opinion was expressed that the Bill should be submitted to the medical profession before being introduced to Parliament.

The War.

THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue:—

Killed.

Capt. F. J. H. T. Frere, M.C., R.A.M.C., qualified at Durham in 1913 and held the appointment of house surgeon at Newcastle Royal Infirmary. He joined the R.A.M.C. on the outbreak of war and saw service in Gallipoli. The award of the Military Cross was announced in THE LANCET of Feb. 5th, 1916, p. 321.

Capt. O. Hairsine, M.C., R.A.M.C., was a student at Middlesex Hospital, and qualified in 1914, just prior to the outbreak of war, and thereupon joined the R.A.M.C. Capt. Hairsine was in the retreat from Mons, and the award of his Military Cross was recorded in THE LANCET of Jan. 22nd, 1916, p. 215.

Capt. L. E. Clark, Canadian A.M.C.

Capt. D. R. King, R.A.M.C., qualified at Glasgow in 1914 and shortly afterwards joined up.

Died of Wounds.

Lieut. W. A. Smith, R.A.M.C., attached Royal Field Artillery.

Wounded.

Capt. O. De Muth, R.A.M.C.
Lieut. A. G. H. Smart, R.A.M.C.
Capt. W. M. Cox, R.A.M.C.
Capt. A. C. Giles, R.A.M.C., attached S. Lanc. Regt.
Capt. J. McMillan, R.A.M.C., attached M.G.C.
Col. A. W. N. Bowen, R.A.M.C.
Capt. P. Hudson, R.A.M.C., attached Hamps. Regt.
Capt. W. B. Loveless, R.A.M.C., attached R. W. Regt.
Capt. H. C. D. Miller, R.A.M.C.
Capt. C. Witts, M.C., R.A.M.C., attached High. L.I.
Capt. K. J. Yeo, R.A.M.C., attached M.G.C.
Capt. J. J. Sinclair, R.A.M.C.
Capt. C. H. Carlton, R.A.M.C., attached London Regt.
Capt. A. J. McCreadie, R.A.M.C., attached Border Regt.
Capt. A. C. Court, R.A.M.C.
Capt. R. O. H. Jones, R.A.M.C.
Capt. J. Marshall, New Zealand M.C.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualties among the sons of medical men are reported:—

Second Lieutenant C. P. Lewis, Royal Engineers, killed in action, only son of Dr. P. Lewis, of Brixton-hill, London, S.W.

Second Lieutenant I. H. McCaw, Royal Irish Rifles, wounded, only son of Dr. J. McCaw, of Dublin-road, Belfast.

Second Lieutenant C. L. Green, Essex Regt., attached Royal Flying Corps, killed in action, elder son of Dr. E. F. S. Green, of South Norwood, London, S.E.

THE REMUNERATION OF THE MEDICAL STAFFS OF V.A.D. HOSPITALS.

It is now some time since Dr. Howard Marshall raised the question in a letter to the *Times* of the remuneration of the medical staffs of V.A.D. hospitals, but nothing has been done to place the position of these officers on a satisfactory basis. It has come out, mainly as the result of Dr. Marshall's action, that two years ago a form was issued, under the authority of a War Office letter, to the various commands, in accordance with which remuneration could be claimed by the medical officers of V.A.D. hospitals, but the existence of the form was not made known to the medical officers. Further, the remuneration, when given to certain of the officers, was construed as a private transaction. It may be that many medical officers of V.A.D. hospitals are prepared to give their services gratuitously and to defray their own out-of-pocket expenses, but to many others this must be a grave hardship. The whole question has for some time been under the consideration of the Central Medical War Committee, and it is essentially one where the War Office authorities should be ready to coöperate with that body and other representative bodies in putting matters on a sound financial footing.

OBITUARY OF THE WAR.

PERCY EAST LONES, M.R.C.S. ENG.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain P. E. Lones, who was killed in action on April 28th, at the age of 30, was the only surviving son of Dr. T. E. Lones, of H.M. Patent Office, and King's Langley, Herts. Educated at Watford, Dudley, and University College, London, he received his medical training at University College Hospital. Joining the University of London O.T.C. in August, 1914, he obtained the qualification of the Conjoint Board in the following January, and his commission in the R.A.M.C. a month later. In March, 1916, he left for India attached to the 1st Durham Light Infantry, and saw service in the Mohmand rising. Returning to England last February, he was sent to France, where he was killed instantaneously by a shell when in command of the bearers at a regimental aid-post.

Captain Lones was by nature courageous. Swimming was his chief sport, and in the summer of 1910 he saved a boy from drowning in the Thames. His senior officer writes of him as a reliable officer whose loss was keenly felt by the division. "Brave to a fault, always content, no matter what his lot. We all considered him a great acquisition to the ambulance." Captain Lones married Marian, daughter of Edward Wadsworth, of Harlesden, and leaves a widow and an infant daughter.

FREDERICK HUNTON, M.D., B.S. DURH.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain F. Hunton, who fell in action in Palestine on May 5th, was 48 years of age and a native of Stockton-on-Tees. He was educated at the Bishop Auckland Grammar School, taking his M.B., B.S. Durh., in 1891, from the College of Medicine in Newcastle-upon-Tyne, and his M.D. degree two years later. After acting as assistant to Dr. Blandford, of Norton, for four years, he became resident medical officer to the Stockton-on-Tees Union Hospital till 1898, when he purchased a practice at Sedgefield, co. Durham, becoming medical officer of health to the rural district, and continuing there till 1914, when he volunteered for active service in Egypt, and received a commission in the R.A.M.C., T., attached to the Northumberland Hussars, but was posted to the 53rd Welsh Casualty Clearing Station. After seeing the wounded come in from recent actions near Gaza, and on one occasion working amongst them for 84 hours at a stretch with only four hours' sleep, he was running to succour the men who were wounded during a bombing raid when he himself received a piece of the bomb, which pierced his chest and killed him instantaneously.

A medical friend writes of Captain Hunton:—"He was the ideal of a country practitioner, and by his cheery courage his professional skill, and his sterling character, he exercised a wide influence for good. He was one of those who loved the country. 'I know every tree on my rounds, and I shake hands with them as I pass,' he was wont to say, and being a great huntsman the winter in the South Durham country had its special charm for him. But before hunting he always did his round of patients, and duty was never better done, nor work more faithfully accomplished than by Hunton. Few men underwent more accidents: he broke his femur at football and had 1½ in. of shortening in one limb; he broke his collar-bone on a bicycle; he fractured his ribs on at least two occasions; and he had one kidney removed after a hunting accident. After joining the Army he had a comminuted fracture of the tibia, which was plated and recovered. I have never met a braver man, and in addition to overflowing physical courage he possessed moral courage in an equal degree. He asked only the question, 'Is it right?' and when satisfied he did not know fear." Captain Hunton was twice married and leaves a son and four daughters.

PERCY HERBERT BURTON, M.R.C.S. ENG.,

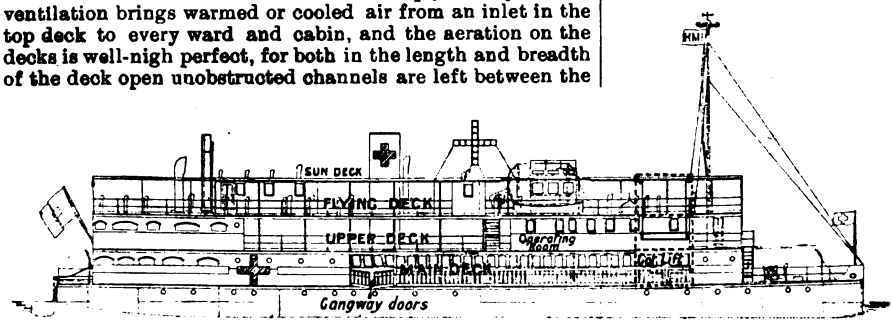
CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain P. H. Burton, who was killed in action in France on May 13th, was the youngest son of the late Joseph D. Burton, of Cambridge Heath. He studied medicine at the London Hospital, where he became surgical clinical assistant qualifying in 1914. Shortly after the outbreak of war he offered his services to the War Office and was attached to the London Regiment, with which he served continuously, first in this country and latterly in France, from the beginning of 1915 to the date of his death. He had only returned to his battalion, after a short period of leave, four days before he fell. Of a consistently cheery and bright disposition, Captain Burton possessed an inherited and intuitive love for his work, which had an absorbing interest for him beyond that of professional duty. Letters from his superior officers testify to the value which these qualities conferred on his work as a military medical officer. Captain Burton leaves a widow but no children.

CHARLES RYLEY, M.R.C.S. ENG., D.P.H.,

MAJOR, ROYAL ARMY MEDICAL CORPS.

Major C. Ryley, who died on active service on May 4th, was only son of the late Charles Ryley, sometime of New Zealand. He took his medical course at St. Mary's Hospital, qualifying in 1901, and holding resident appointments there and at the Paddington Green Hospital for Children. In 1904 he joined the Royal Army Medical Corps, and after seeing service in China and Bermuda was sent to France in 1916 as Deputy Assistant Director of Medical Services. After an attack of pericarditis in July he never recovered his health completely, but insisted on remaining at his work, "always cheerful and amusing," according to the testimony of his colleagues. Finally he collapsed while on horseback and fell to the ground, being found dead when he was picked up. Major Ryley married in 1905 Christine, daughter of Major John Francis O'Brien, and leaves a widow and two sons.



MIDDLESEX HOSPITAL MOBILISATION CENTRE.

The officer personnel of the unit authorised by the War Office to be raised at the Middlesex Hospital Mobilisation Centre by Lieutenant-Colonel Sir James K. Fowler is complete. A supplementary list has been formed from which vacancies will be filled as they arise. This list remains open. Many offers which could not be accepted have been received from men beyond the limit of age for service abroad. Nurses and V.A.D.'s trained at the Middlesex Hospital are still required for service with this unit. The age-limit is 45 years. Applications should be addressed to the Lady Superintendent, Middlesex Hospital, W.

HOSPITAL SHIPS ON THE TIGRIS.

NEWS has recently been received by the British Red Cross of the safe arrival at Basra of the *Nabha*, one of a new fleet of hospital ships built to ply on the upper shallow reaches of the river Tigris. The hospital ship of which we give a profile view below is a similar vessel to the one recently inspected by the King before being sent out. With cot accommodation for some 200 patients, the ship draws less than 3 feet 6 inches of water, and can turn in twice its own length of 160 feet on account of an ingenious quadruple rudder. The main or lower deck, arranged as a hospital for serious cases, can be closed in for warmth—it can be cold as well as hot on the Tigris—while the windows turn on pivots in order to catch any available breeze in the hot weather. A plenum system of ventilation brings warmed or cooled air from an inlet in the top deck to every ward and cabin, and the aeration on the decks is well-nigh perfect, for both in the length and breadth of the deck open unobstructed channels are left between the

Twin Screw Motor Hospital Ship.

cots for the air to circulate freely, while an electric fan is provided for every cabin and for every group of four cots on deck. Gangway doors allow the direct embarkation of fracture cases on to either side of the several decks from which, when necessary, a cot-lift conveys them to the operating theatre on the upper deck. The arrangements have been designed by Lieutenant-Colonel R. M. Carter, I.M.S., to provide perfect comfort for the patients and facilities for their medical care and supervision within a minimum space, and in all this he has been eminently successful. The medical and surgical equipment is specially complete down to an abundant supply of the drugs likely to be required in a tropical country.

CEREBRO-SPINAL FEVER IN CONNEXION WITH THE WAR.

We have received the following report on cerebro-spinal fever in the county of Norfolk for 1915 from Dr. J. T. C. Nash, the county medical officer of health :—

Cerebro-spinal fever has shown a tendency to increase in England and Wales during the last three or four years. In the administrative county of Norfolk in 1915 there were 31 notifications—10 soldiers and 21 civilians. Of the 20 civilian cases of which I have notes, 11 were adult females, and 6 of the remaining 9 were children. Of the 3 males, one was a baker, another a postman, whose occupations might bring them into touch with soldiers. Of the first 10 cases of cerebro-spinal fever notified 6 were soldiers, 1 was the sister of a soldier, himself a victim, and 2 were females who came in contact with soldiers.

The first intimation I had of cerebro-spinal fever in Norfolk was from the military, who informed me, on Jan. 30th, that two cases occurred in troopers in the Aylsham district, who had been removed to the Norfolk and Norwich Hospital on Jan. 26th, and the diagnosis had been confirmed bacteriologically. One man had returned from Wales about a fortnight previously. On Jan. 30th there was also a notification of a case at Cromer—a servant girl who had mixed with soldiers, and of another case, a female, in the Aylsham district who also mixed with soldiers. The next case was a soldier in Freebridge Lynn district, notified on Feb. 6th. On Feb. 20th there was the notification of a farm-hand at Fritton, who was taken ill on Feb. 9th and developed symptoms of "brain fever" on Feb. 12th; he was removed to the Norfolk and Norwich Hospital, where he died 36 hours later. A post-mortem examination showed the presence of cerebro-spinal meningitis, but the meningococcus failed to grow from the cerebro-spinal fluid taken after death. No examination had been made during life.

The next case notified, on Feb. 21st, was a soldier who came home to Wymondham on leave from Felixstowe on Feb. 6th. He fell ill suddenly on the 8th and was first thought to be suffering from enteric fever. My attention was asked on Feb. 22nd. On Feb. 23rd he was removed with his sister (also now suffering from cerebro-spinal fever—confirmed by bacteriological examination of cerebro-spinal fluid) to hospital. On March 6th I had a notification of a *military* case at Hunstanton, and of another *military* case at Hilgay Fen, Downham. (This man had come from Felixstowe.) A further military case was notified from King's Lynn on March 13th, and yet another soldier from Thetford on March 22nd.

As I informed Dr. Farrar, of the Local Government Board, on this date, there had been up to this time 10 notifications of cerebro-spinal fever in the administrative county of Norfolk—4 in January (2 soldiers), 3 in February (2 soldiers and 1 civilian—a sister of one of the affected soldiers), and 2 in March (both soldiers). The other civilian case was the case diagnosed on post-mortem examination at the hospital. On March 27th a child, aged 4, was notified from a village in Walsingham rural district in which troops were billeted; and on the same date a military case was notified from Sheringham. On March 30th a female civilian case was notified from Brundall, near Norwich, and a male civilian case (a postman) from Cromer.

On March 31st, 1915, I sent a circular letter to all the district medical officers of health pointing out that cases of cerebro-spinal fever were occurring mostly among troops, and stating that the military authorities had made arrangements with Dr. G. P. C. Claridge, of St. Giles Plain, Norwich, to make bacteriological examinations of suspected cases and contacts. As a result Dr. Claridge's services were arranged for in all districts where they were required or where there was any likelihood of cases of cerebro-spinal fever occurring.

On April 1st I received a military communication that a military servant who had been at Thurlton, near Loddon, had fallen ill with cerebro-spinal fever at Camberley. A suspected civilian case on April 4th was not confirmed by bacteriological examination. On April 6th a female child, aged 9, was notified at Loddon. The house had been visited by a soldier relative a few days previously. On April 8th a male civilian (baker) was notified in the Aylsham district. On April 12th I received a notification of a female (husband a soldier who had visited her eight days previously) in Erpingham district, near Cromer. On April 15th a female, aged 21, was notified from the Marshland district. She had been in contact with soldiers in King's Lynn. On April 17th a military case was notified from Diss; inquiries showed that he was merely *en passant* from Oakley to Cambridge. On April 26th a notification was received from London of an officer who had recently been at Loddon (Norfolk). Swabbing of military contacts in Norfolk showed a few "carriers" (13 ?). The officer had left Norfolk ill on the 16th. (This case, the Camberley case, and the Loddon child notified on April 6th have apparently something in common.) On May 1st a civilian case was notified from Depwade. No further cases were reported during May. The particulars to this date show 10 military and 12 civilian cases (9 females, 3 males), all of the latter having more or less intimate relations with

soldiers. The sex incidence among civilian cases is noteworthy.

This completes the first chapter of the history of cerebro-spinal fever in Norfolk; the rest of the story can be summarised as follows:—

Chapter 2.—A period of six weeks having elapsed, a notification of cerebro-spinal meningitis in a female child, aged 2, was received on June 12th from the Freebridge Lynn district. Soldiers billeted about two miles away. On June 19th a notification was received of a male civilian case from West Lynn. The man had come from Hunstanton, where troops were stationed and where a military case was notified in March. These two cases were in north-west Norfolk.

Chapter 3.—A period of about two and a half months having elapsed, two children at Long Stratton were notified as suffering from cerebro-spinal fever on August 28th, and on the same date a military case was notified from King's Lynn.

Chapter 4.—No further cases for two months; then 3 cases in one house, notified on Oct. 30th, Nov. 6th, and Nov. 17th respectively—all females (one a baby). Contact of the first case with a soldier was clearly established; the others were house contacts.

Chapter 5.—The last notification of cerebro-spinal fever in the year was that of a male civilian, a solicitor living near and frequently in Norwich. Exact source of infection was not traced, but cases and carriers were occurring from time to time in Norwich. Thus, in the last half of the year 7 cases were notified, of which only 1 was a soldier. Of the six civilian cases 3 were young children, 2 were adult females, and 1 an adult male.

The history of the incidence of the disease during the year indicates a gradual transference from the military to the civilian section of the population, the first few cases being either soldiers or intimately connected with soldiers. Later no doubt a vicious circle was established—soldiers and civilians affecting each other.

The difficulty in dealing with outbreaks of cerebro-spinal fever lies chiefly in the fact that for every case there are generally found numerous "carriers" of the germ among the contacts. These have all to be subject to bacteriological examination, quarantine, and some form of treatment. It would not be difficult to overlook a carrier, and the manner in which the disease was held in check speaks volumes for the efficient aid given by Dr. Claridge.

THE HONOURS LIST.

The following awards to medical officers are announced:—

Distinguished Service Order.

Major Robert Thornton Meadows, R.A.M.C.

For gallant and meritorious service on the occasion of the mining of a hospital ship.

Capt. Ernest Stanley Stork, R.A.M.C., attached Yeomanry.

For conspicuous gallantry and devotion to duty. He displayed untiring energy and devotion to duty in evacuating a large number of wounded under heavy fire. He set a magnificent example of courage and determination.

Capt. (temp. Major) Alfred Charles Foster Turner, R.A.M.C.

For conspicuous gallantry and devotion to duty. He attended wounded under heavy fire day and night without rest. He was ever present along the line from the A.D.S. to the most advanced trenches, and on several occasions faced enemy artillery barrages in order that reserves of stretcher-bearers might reach their objectives.

Capt. William Ferguson Wood, R.A.M.C., Spec. Res., attached Hussars.

For conspicuous gallantry and devotion to duty. Under most trying circumstances and heavy fire he collected and tended the wounded without rest or food. He frequently made dangerous tours looking for wounded men.

Bar to the Military Cross.

Capt. James Alwin Colville Scott, M.C., R.A.M.C., attached Durham Light Infantry.

For conspicuous gallantry and devotion to duty. He behaved with great courage and coolness in attending the wounded under heavy shell fire. For two days he worked continuously, with an utter disregard for his own safety. By his efforts he was able to ensure the rapid evacuation of the wounded, and undoubtedly saved many lives. (The award of the Military Cross was announced in THE LANCET of Jan. 6th, 1917, p. 38.)

Military Cross.

Temp. Capt. Vincent Edgar Badcock, R.A.M.C., attached Highland Light Infantry.

For conspicuous gallantry and devotion to duty. He has behaved in a most gallant manner on several occasions in attending to wounded under intense shell fire, showing an utter disregard of personal danger, and setting a fine example to all.

Temp. Capt. James Harding Barry, R.A.M.C., attached London Regiment.

For conspicuous gallantry and devotion to duty. He showed the utmost coolness and bravery in going out under heavy machine-gun fire and assisting to bring in and attend wounded men. Throughout he set a splendid example to all.

Temp. Capt. Bertram Henry Barton, R.A.M.C.

For conspicuous gallantry and devotion to duty. He worked continuously under very heavy fire, and succeeded in bringing in many wounded men. His devotion to duty saved many lives.

Temp. Capt. Eric Biddle, R.A.M.C.

For conspicuous gallantry and devotion to duty. He showed great gallantry in supervising the removal of wounded from a heavily shelled area. By his untiring energy and disregard of personal danger he saved many lives.

Capt. Richard Thompson Cæsar, R.A.M.C.

For conspicuous gallantry and devotion to duty. On taking over the line, the cellars of the village were full of wounded. He proceeded with bearers to search all the cellars and organised removal of patients. Although the shelling was heavy and practically continuous, he remained all day and succeeded in clearing the village of all wounded.

Temp. Capt. John Donal Carroll, R.A.M.C., attached Royal Warwickshire Regiment.

For conspicuous gallantry and devotion to duty. An observation post had been hit, he immediately went to the spot and attended the wounded, although the enemy continued to concentrate heavy shell fire on the post.

Temp. Capt. James Alphonsus Conway, R.A.M.C., attached Oxford and Bucks Light Infantry.

For conspicuous gallantry and devotion to duty. He worked indefatigably under heavy fire, and by his personal attention saved the lives of a number of men. He set a fine example to all ranks.

Temp. Lieut. A. Yeshwant Dabholkar, I.M.S.

For conspicuous gallantry and devotion to duty. Although himself wounded, he displayed great courage and determination in tending wounded men under heavy fire. He set a splendid example to those around him.

Temp. Lieut. Erach Ruttonji Daboo, I.M.S.

For conspicuous gallantry and devotion to duty. He went forward at great personal risk and dressed many wounded men under very heavy fire. He was himself wounded.

(The award of the Military Cross to Temp. Lieut. Dabholkar and Temp. Lieut. Daboo has been announced in a previous issue of THE LANCET, and the deeds are now added.)

Temp. Capt. Oswald John Day, R.A.M.C.

For conspicuous gallantry and devotion to duty. He worked continuously under very heavy fire, and was responsible for the evacuation of a large number of wounded.

Capt. Walter Elliot Elliot, R.A.M.C., Spec. Res., attached Dragoons.

For conspicuous gallantry and devotion to duty. He worked continuously throughout the night tending the wounded under heavy fire. His devotion to duty saved many lives.

Capt. Henry William Evans, R.A.M.C., Spec. Res.

For conspicuous gallantry and devotion to duty. He showed the utmost bravery and zeal when commanding a stretcher-bearer division. He directed the bearers and tended the wounded in the open. By his exertions he secured the efficient clearing of the wounded over very long distances.

Capt. Alfred George Timbrell Fisher, R.A.M.C.

For conspicuous gallantry and devotion to duty. The advanced dressing station of which he was in command was destroyed by shell fire, and although himself severely shaken, he succeeded in forming a fresh dressing station.

Temp. Capt. Frederick George Flood, R.A.M.C., Spec. Res.

For conspicuous gallantry and devotion to duty. He displayed great courage and determination in tending the wounded under very heavy fire. His disregard of personal danger inspired all ranks. He has previously done fine work.

Capt. Arthur Stuart Hebblethwaite, R.A.M.C., attached London Regiment.

For conspicuous gallantry and devotion to duty. He organised and trained a detachment of stretcher-bearers and supervised their operation under heavy fire. All casualties were cleared within a short time of the completion of the operations. This was due to the excellent training and example set by this officer.

Temp. Capt. Daniel Kennedy, R.A.M.C., attached Lancers.

For conspicuous gallantry and devotion to duty. He tended the wounded under very heavy machine-gun shell fire, to which he was continually exposed. It was owing to his bravery and untiring devotion that many lives were saved.

Temp. Capt. John Low, R.A.M.C.

For conspicuous gallantry and devotion to duty. He brought forward his bearer subdivision and established a dressing station under heavy fire, thereby relieving the regimental aid-posts. He worked continuously for 36 hours.

Capt. Gilbert Moore, R.A.M.C.

For conspicuous gallantry and devotion to duty. He was in command of the evacuation of the wounded for several weeks on an advanced front. He displayed skill in working his dispositions, and personally superintended the evacuation under heavy shell fire.

Capt. William Fraser Munro, R.A.M.C.

For conspicuous gallantry and devotion to duty. He worked continuously for 48 hours under very heavy fire, and was responsible for the evacuation of a large number of wounded. He set a splendid example to all ranks.

Capt. John Dover Proud, R.A.M.C., Spec. Res.

For conspicuous gallantry and devotion to duty. He worked continuously for 48 hours under heavy fire and succeeded in bringing in many wounded men.

Temp. Capt. Arthur Wilmot Raymond, R.A.M.C.

For conspicuous gallantry and devotion to duty. He organised and led a rescue party to dig out some men partially buried by the explosion of a shell in a captured enemy gun-pit. He set a splendid example of courage and determination.

Temp. Capt. Arthur Paul Saint, R.A.M.C., attached King's Royal Rifle Corps.

For conspicuous gallantry and devotion to duty. He displayed great courage and determination in tending the wounded under heavy fire. His devotion to duty saved many lives.

Temp. Capt. Humphrey Meigh Stephenson, R.A.M.C., attached Rifle Brigade.

For conspicuous gallantry and devotion to duty. He tended the wounded under heavy fire, and showed a complete disregard for his personal safety. He set a magnificent example throughout.

Temp. Capt. James Williamson Tocher, R.A.M.C.

For conspicuous gallantry and devotion to duty. He displayed great courage and determination in attending to wounded for many hours during an intense hostile bombardment. He set a fine example to all ranks.

Temp. Capt. Frank Muir Walker, R.A.M.C., attached Royal Horse Artillery (Lieut. C.A.M.C.).

For conspicuous gallantry and devotion to duty. He has displayed the utmost gallantry and devotion to duty when under heavy fire. Particularly when he went through a heavy barrage to some wounded men, and tended them in the open for an hour.

Temp. Capt. Thomas Arnold Watson, R.A.M.C., attached King's Royal Rifle Corps.

For conspicuous gallantry and devotion to duty. He displayed great courage and determination in tending the wounded under heavy fire. His devotion to duty saved many lives.

Capt. Charles Owen James Young, R.A.M.C., Spec. Res.

For conspicuous gallantry and devotion to duty. He went out under heavy shell fire and attended several wounded men in the open. He has on previous occasions shown fine disregard of personal danger in the face of heavy fire.

Capt. William Robert Aspinall, Australian A.M.C., attached Field Artillery.

For conspicuous gallantry and devotion to duty. He displayed the utmost courage and devotion in tending the wounded under heavy fire, and assisting them to places of safety until they could be evacuated. He showed the greatest gallantry throughout.

Capt. Ronald Lennox Henderson, Australian A.M.C., attached Infantry.

For conspicuous gallantry and devotion to duty. He displayed great courage and determination in tending the wounded under very heavy fire. His devotion to duty saved many lives.

Capt. William Duncan Kirkland, Australian A.M.C., attached Field Artillery.

For conspicuous gallantry and devotion to duty. During hostile shelling two ammunition dumps were set on fire also causing several casualties. He immediately went to the assistance of the wounded, and, regardless of heavy shell fire and numerous explosions, dressed their wounds. He has at all times set a fine example.

Capt. Stanley Vincent O'Regan, Australian A.M.C., attached Infantry.

For conspicuous gallantry and devotion to duty. He worked continuously throughout the day tending to the wounded under very heavy fire. He set a fine example to all ranks.

Capt. Hugh Alexander Wyllie, Australian A.M.C., attached Infantry.

For conspicuous gallantry and devotion to duty. He tended the wounded continuously for two days under heavy fire. He set a splendid example of courage and determination.

GIFTS OF AMBULANCE WAGONS.—Motor ambulance wagons of various types which have been presented to the Scottish Branch of the Red Cross Society were on view in Glasgow lately, and were formally handed over in the transport headquarters there. The wagons consist of a field kitchen, a workshop, two vans for carrying supplies, two Red Cross wagons, and an ambulance with accommodation for four cot cases, the gifts of the Scottish Coal Owners and the National Union of Mine Workers in Scotland. A mobile X ray wagon, with complete equipment, was furnished by the Scottish Farmers' Union, and a dental wagon by an anonymous donor.

THE LANCET, VOL. I., 1917: THE INDEX.

THE Index and Title-page to the volume of THE LANCET completed with the issue of June 30th will be ready in July. Owing to the continued shortage in the paper supply, the Index will not be issued with all copies of THE LANCET, as was the custom prior to the War. Subscribers who bind up their numbers are requested to send a post-card to the Manager, THE LANCET Office, 423, Strand, London, W.C. 2, when a copy of the Index and Title-page will be supplied free of charge.

THE SERVICES.

ARMY MEDICAL SERVICE.

Major (temp. Lieut.-Col.) H. A. Ballance, R.A.M.C., T.F., to be temporary Colonel.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. O. W. A. Elsner, D.S.O., to be temporary Colonel whilst employed as Assistant Director of Medical Services of a Division.

Lieut.-Col. E. M. Morphew, D.S.O., to be temporary Colonel whilst Assistant Director of Medical Services of a Division.

Temp. Lieut.-Col. G. S. Buchanan, having resigned his appointment, reverts to the rank of temporary Honorary Lieutenant-Colonel.

To be acting Lieutenant-Colonels: Capt. W. H. C. Lunn whilst in command of a Field Ambulance and Major Thomas B. Unwin whilst in command of a Stationary Hospital.

Major Albert E. B. Wood relinquishes the acting rank of Lieutenant-Colonel on reposting.

Temp. Major A. M. Leake, V.C., to be acting Lieutenant-Colonel whilst in command of a Field Ambulance.

To be Temp. Majors: W. L. Braddon and Temp. Capt. H. S. Raper.

Temp. Lieut. P. J. O'Sullivan to be temporary Captain.

To be Temporary Captains: E. T. C. Milligan, H. D. Duke, R. Friell, G. R. Lawless, R. F. Yencken, A. Burton, C. R. Smith, J. Pugh, L. Bromley, C. W. B. Littlejohn, A. Fletcher.

To be temporary Lieutenants: J. Glaister, E. J. Stuckey, R. G. Struthers, J. Cullen, W. M. McDonald, R. E. V. Hale, G. Adam, J. A. Valentine, H. Daw, T. D. Webster, J. W. Trevan, J. C. Marshall, J. J. Keyns, P. J. Verrall, B. Hart, F. E. Higgins, J. B. Cooke, C. E. Lowe, S. C. Wilkinson, C. C. W. Pasco, F. Wilkinson, G. I. Cumberlege, J. H. Trench, J. L. Green, F. B. Penfold, A. M. A. James, D. S. Macbean, H. E. Jones, G. Hardwicke, H. A. De Morgan, E. L. M. Lobb, W. R. O'Keefe, H. W. Fisher, C. E. Waldron, D. M. Ross, A. T. W. Forrester, N. R. Ussher, S. P. Rowlands, C. C. W. Mays, A. Macdonald, G. S. Ewen, G. A. J. M. Loughnan, J. A. Wood, G. B. P. Davis, W. B. Blandy, F. W. W. Smith, P. O. Moffat, J. S. Higgs, S. Carter, H. W. Elwell, G. P. Young, A. H. McCandlish, G. W. Sudlow, C. H. Waddell, R. H. Robbins, S. McMurray, G. S. Robertson, R. K. Robertson, H. F. Warner, S. C. Shanks, C. Murray, W. S. George, G. Chalmers, R. Jamison, T. S. D. Enderby, F. L. Brewer, L. W. Roberts, W. B. H. Dundee, W. MacKenzie, L. Fern, H. G. Rashleigh, R. W. D. Hewson, J. G. Cooper, D. M. Bochan, W. Sanderson, F. Atthill, H. G. Drake-Brockman, T. J. George, J. F. Weston, F. Whincup, A. Emerson, H. A. Whitcombe, P. Hall-Smith, H. L. Galletly, W. A. Elwood, E. A. A. Saunders, A. I. Cooke, H. E. Heapy, J. C. Mann, F. W. Ritson, R. G. Smyth, L. B. Perry, F. Thompson, E. B. M. Price, J. A. MacKenzie, J. F. Douse, E. Wight, R. Gauld, G. M. Davies, J. A. Ross, R. C. Cummings, F. Talbot, J. E. Scott, S. Slade, A. J. Rae, A. Mason, J. H. Nichol, J. D. Bridger, J. P. McGowan, F. H. R. Heath, D. C. Dobell, T. E. Banister, C. I. Milne, A. H. John, J. Renwick, F. E. Wilson, H. A. Lyth, C. H. Pepper, A. G. H. Lovell, A. R. F. Hay, W. A. D. King, S. C. Ellison, A. F. R. Conder, A. Gilchrist, G. H. Shaw, J. Donaldson, A. L. Robinson, G. A. Johnstone, A. W. F. Edmonds, L. W. Shadwell, J. G. Macqueen, J. Brydon, A. J. McConnell, R. S. Frew, J. L. Hawkes, J. B. Macalilan, C. H. Wilson, J. A. Durant, H. Brayshaw, R. G. Barlow, H. A. Williams, J. Jeffrey, M. W. Cantor, H. V. Swindale, H. N. Matthews, N. Morris, J. A. M. Clark, J. Dick, J. A. Currell, T. C. MacKenzie, J. A. Struthers, F. C. Morgan, W. P. Over, G. A. F. Heyworth, G. V. Anderson, A. Leeming, J. Menton, F. J. Child, C. A. A. Dighton, C. G. MacMahon, E. J. Fisher, R. H. Robinson, J. H. Moore, W. H. Bush, J. A. Jamieson, K. C. Edwards, A. C. Brown, R. H. Dixon, W. N. May, L. M. Markham, H. Christal, A. Gregory, W. M. T. Wilson, M. R. Dobson, L. S. Hooper, R. M. Erskine, R. Robertson, J. D. Clay, L. H. Burner, R. B. Radcliffe, J. Tait, J. C. L. Day, A. C. Sturrock, D. Gray, A. B. Rooke, H. E. Martyn, J. B. Sandilands, A. B. Robertson.

The undermentioned are granted temporary honorary rank whilst serving with the Irish Counties War Hospital: As Lieut.-Colonel: S. S. Pringle. As Major: W. G. Harvey. As Captain: H. de Lisle Crawford.

T. H. Brown, late temporary Lieutenant, to be honorary Lieutenant.

Officers relinquishing their commissions: Temp. Lieut.-Col. A. S. Woodwark (granted the rank of Lieutenant-Colonel). Temporary Captains: L. M. Breton (on account of ill-health), J. F. MacKenzie (on account of ill-health), A. Renshaw, E. V. Frederick, R. H. Drennan (on account of ill-health). Temporary Lieutenants: C. E. L. Burman, H. L. Craig, G. H. Clement, L. W. Kergin, J. S. Strachan (on account of ill-health).

SPECIAL RESERVE OF OFFICERS.

Lieuts. W. B. Wilson and J. B. Hume to be Captains.

To be Lieutenants: L. Jefferson (from Queen's University, Belfast Contingent, O.T.C.); W. H. White, D. J. H. Jones, and J. Braun (from University of London Contingent, O.T.C.); W. R. Matthewson (from Edinburgh University Contingent, O.T.C.); R. N. Burton.

Major H. G. Smeeth relinquishes the active rank of Lieutenant-Colonel on reposting.

TERRITORIAL FORCE.

Majors to be temporary Lieutenant-Colonels: D. J. Graham, F. D. Boyd, C.M.G., J. G. Andrew, R. A. Veale, J. H. Ray.

Major J. Ward to be acting Lieutenant-Colonel whilst commanding a Field Ambulance.

Captains to be temporary Majors: W. E. Alderson, L. G. J. Mackay, A. R. Bearn, H. B. Whitehouse, W. B. Secretan, R. Ollerenshaw, F. E. Tylecote, T. B. Mount, J. H. Cobb, A. Young, A. A. S. Skirving, C.M.G., J. Hason, J. McC. Johnston, J. Henderson.

Capt. and temp. Major (acting Lieut.-Col.) T. H. Peyton, D.S.O., reverts to the temporary rank of Major on ceasing to command a Field Ambulance.

Capt. (temp. Major) A. H. Horsfall, D.S.O., relinquishes his temporary rank on alteration in posting.

Captains P. R. Wrigley and D. H. Gore have been restored to the Establishment.

To be Lieutenants: L. Hawkes, W. V. Barritt.

Capt. G. R. Ellis relinquishes his commission on account of ill-health contracted on active service, and is granted the honorary rank of Captain.

Surg.-Gen. W. R. Edwards, C.B., C.M.G., I.M.S., has been appointed an Honorary Physician to the King, vice the late Surg.-Gen. Sir B. Franklin, K.C.I.E.

THE DEVELOPMENT OF TRAINED NURSING IN FRANCE.

BY E. MONTIZAMBERT.

THERE is a fairly widespread idea that since the expulsion of the religious orders there have been in France no properly trained nurses for the sick. The number of women who have adopted the profession of nursing without proper equipment and the unsupervised direction of some of the private registry offices for sick nurses may give some foundation for this opinion.

It is not proposed to deal here with the schools organised by any of the three branches of the French Red Cross. The war has made these Red Cross organisations—especially the efficient school conducted by Mademoiselle Genin at the Hôpital École in the Square des Peupliers—very well known to the general public. There are, however, four or five admirable training schools organised in Paris in the last few years, and their steady and satisfactory growth will inevitably result in the disappearance of tolerated incompetency at an early date. The existence of excellent training schools for civilian hospitals or for private nursing remains almost unsuspected outside of France, and one constantly hears the unfounded statement, "What a pity there are no trained nurses in France!" One reproach most frequently made against the profession of trained nurses in France was that the members were drawn from an ill-educated class. That this was so was partly owing to the fact that nursing the sick was not considered a suitable occupation for well-bred women obliged to earn their living, and partly because of the unorganised and often unsatisfactory conditions under which private nursing was carried on.

Training School of Nurses for Daughters of Gentlemen.

These difficulties were smoothed away by Madame Achille Fould, who, at her own expense and after overcoming many difficulties, founded in 1905 a training school of nurses for the daughters of gentlemen. In one of the poorer quarters of Paris, a site was found where, in addition to buildings already occupied by the charitable activities of the sisters of Saint Vincent de Paul, a hospital for both sexes and excellent quarters for the pupils of the training school were constructed. Everything of hygiene and convenience has been carefully thought out. The details of the operating-rooms, the sterilising plants attached to every ward, and the radiography apparatus are all of the latest device, and every corner of the buildings, as well as every thing they contain, presents the polished cleanliness which marks a new era in French hospital work. An excellent dispensary, airy and spacious, with comfortable oaken benches for the patients and spotless dressing-rooms fitted up with the latest appliances is the scene of part of the hospital work, where the pupils take turns to be on duty. After a probation of three months at the school, the pupils are admitted as candidates for the "Diplôme Supérieur," given at the end of a two years' course of training. In the first year, they receive their theoretical instruction as well as a certain amount of practical work in their own hospital. At the end of this first year, still in their own school hospital, the pupils take courses in the "services" of surgery, ophthalmology, oto-rhino-laryngology, electrotherapy, massage, mechanotherapy, pharmacy. After that come supplementary courses in contagious diseases, maternity, and medical clinics in the different hospitals of the "Assistance Publique." After two months' study in each of the branches of hospital work, the students pass their final examination for the Diplôme Supérieur. The examination consists of a composition on a given theme, a written examination on the lecture notes, and oral questions covering the whole two years' course. The students are very carefully selected with a view to encouraging women of good breeding to take up the private nursing as a profession. Attractive quarters, comprising a bedroom, common sitting-room, and dining-room, are provided for them. During the first year of their training, a fee of £4 a month is supposed to be paid for board, lodging, heating, and laundry, but since the war this rule has been much relaxed. Care has been taken to regulate the conditions under which private nursing is undertaken by the pupils of "La Glacière," as this school is popularly called. A salary of not less than 10 francs a day or night, plus food, laundry and travelling expenses, is exacted, and in no case is the nurse allowed to take her meals with the servants. If there are empty rooms at the school ex-students like to return between their cases. Otherwise they may go to the "Foyer des Infirmières," a *pension* for trained nurses, opened last January at 98, Boulevard Auguste Blanqui. The "Hôpital École" de la Glacière in equipment, organisation, and method of training is worthy of comparison with any of the most up-to-date training schools either in England or America. While a Roman Catholic chapel exists in the grounds, a broad-minded liberality in religious matters gives absolute freedom to the followers of any form of faith. Every graduate does not take up private nursing, but the influence of the "crèche" and other charitable institutions grouped within the walls of what resembles a small village at 35 rue de la Glacière is sometimes seen when a graduate chooses district visiting, dispensary work, or regular hospital work among the poor as her vocation. But these are the exceptions: the majority of the graduates carry out Madame Fould's generous intention of founding, equipping, and defraying the running expenses of a school for professional trained nurses for private cases.

Maison École d'Infirmières Privées.

Another excellent school for trained nurses was organised at 66 rue Vercingétorix by Mademoiselle Chaptal and was recognised by the Government as an "établissement d'utilité publique" in 1911. Mademoiselle Chaptal has studied English institutions and her school is run more or less on English lines. The list of the "Comité de patronage médical" contains 31 of the names of the most brilliant members of the medical profession in France. As the society which directs the "Maison École d'Infirmières Privées" has to cope with different financial conditions from those of "La Glacière," the rules of this school are somewhat different. The regular pupils, at the end of their month's probation, sign a contract for five years with the society. This period includes two years' instruction, after which, on obtaining their diploma, they engage themselves to accept any work given to them by the committee. During these three years 10 per cent. of their salary, as well as a fixed sum of 1 franc a day while they are at work, has to be turned over to the society. The latter undertakes in exchange to obtain work for the graduates. While the principal aim of the school is to train women for private nursing, the graduates are permitted, even during their three years' contract, to accept work in hospitals or clinics. They are allowed to spend their holidays at the Maison École, where the *pension* is fixed at the modest price of 3 francs a day.

The instruction provided is fairly comprehensive. It consists of the probation month, when practical instruction in cooking, housekeeping, &c., and theoretical work in anatomy and physiology is done. Then follows a period of five months' hospital work, when 40 hours per week are spent in the medical wards in addition to the theory lectures given in the Maison École by the hospital staff. After that five months' work is done in the surgical wards, four months in the children's ward, two months of maternity work at the clinic Tarnier, one month at the Pasteur Hospital for Infectious Diseases, and four months in studying special branches such as nervous diseases at the Asile Sainte Anne, eye, ear, throat, and skin, &c. The remainder of the two years' course, which also comprises lectures given at the school in pharmacy, massage, and gymnastics, elementary and professional hygiene, invalid cookery, and a "cours de morale professionnelle," is accounted for by the one month vacation given each year. No examination is made at the end of this two years' course, the "certificat de fin d'études" is signed by the lecturers according to the evidence of the daily notes signed by the doctors under whom the students have worked. Great care is taken in the selection of the students, as Mademoiselle Chaptal's aim has been to raise the standard of trained nursing in France. On the payment of considerably higher fees, students who do not wish to contract a five years' engagement with the society are permitted to receive the same instruction.

Schools for Training District and other Nurses.

The Association pour le Développement de l'Assistance aux Malades, originally founded in 1900 by Madame Alphen-Salvador to encourage district nursing among the poor, at once organised an excellent training school where instruction in all branches of hospital work is given. A preliminary

examination to ensure a certain standard of education on the part of the students is required. There are written and oral examinations at the end of the first and second year, when the rank of "assistant" is obtained. A diploma is only given to those students who, after their two years' course, remain under the direction of the association for three more years. During this time they may be sent out either as private nurses or to fill some post in hospital or district nursing work. Until the war this École Professionnelle at No. 10, rue Amyot, suffered from the drawback of not having a hospital under its own direction, where the students might work under the eye of their instructors. The theoretical work was given at the school, but all the practical work had to be done in one or other of the different hospitals of the "Assistance Publique." This lack has been met last year in the opening of the new hospital school dedicated to the memory of Edith Cavell. The up-to-date hospital, built on a site belonging to the association in the rue Desnouettes, owes its existence to the coöperation of the military authorities, who were faced with the problem of the necessity for hurriedly training the number of amateur nurses whose devotion was not equalled by their knowledge. The military nurses who are sent to the Edith Cavell School are, however, quite apart from the regular students of the school. While they both gain their experience in the same hospital wards, the conditions under which they work are very different. The usual routine of hospital training, with its two years' course, is carried out by the professional students, who have their own class-rooms, &c., quite apart from the nurses who are taking a two months' supplementary course whose incompleteness is acknowledged as inevitable.

While this school is adding to the ranks of efficiently trained nurses every year, its main object still lies in supplying properly trained district nurses primarily for the 5th Arrondissement of Paris. In this work it shares the responsibilities of an organisation called the "Infirmières Visiteuses de France." The wonderful work it is doing for France deserves mention. Founded in February, 1914, and directed by Mdlle. Berthe Milliard, whose name is so well known for her efforts in connexion with the better education of women, this youthful society has already done such excellent work in systematically training nurses for district visiting that it may be regarded as the nucleus of a large body of women who will be able to cope intelligently with the many after-war problems among the poor and the inhabitants of the invaded districts of France. Already 200 fully trained nurses are at work both in Paris and the provinces. The usual course of two years' instruction has been necessarily shortened by the necessities of war-time conditions, but the same care is taken in the recruitment of the students who receive their training at the Laennec Hospital under Dr. Kuss. Special attention is paid to training for tuberculous patients, and the French Government have recognised the excellent work done by these nurses by appealing to them for nurses to staff the military hospitals for men attacked by this disease.

The Training School of the Assistance Publique.

No account of trained nursing in France would be complete without mentioning the splendid new school for training the nursing staff of that immense organisation for caring for the French poor known as the "Assistance Publique." This latest development of modern charity is fittingly installed in the oldest hospital in Paris, La Salpêtrière, which was founded in 1656 as a home for beggars. In the centre of a bewildering maze of buildings, some of which are still devoted to their original uses of asylums for the mentally afflicted, one finds a strikingly new building, opened in 1907, as a training school. Pupils come from all over France, and as the entrance examination is frankly made as simple as possible, the training is open to every class. The students receive free instruction, board, and lodging, and are paid 10 francs a month during their first year and 20 francs a month the following year. They sign a contract to serve for three years in the hospitals of the Assistance Publique at the end of their three years' course, otherwise their *pension* expenses of about £50 a year must be reimbursed.

Every department of the school is most thoroughly up to date, careful provision has been made for the comfort of the nurses, and the immense scale on which hospital work is carried on ensures the benefit of a wide experience for them.

The aim of this vast establishment is solely to supply the needs of its own organisations, but while many of the pupils are content to devote their lives to hospital work with the assurance of a State pension when the age-limit is reached, many of them ultimately take up private nursing after their five years' engagement is finished and are able to give to their patients the skill and knowledge they have gained under the direction of the most brilliant specialists in France.

Unhygienic conditions in certain hospitals may still exist, but a new era in nursing has begun, and the skill and science of the properly trained French nurse are second to none.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—An ordinary meeting of the Council was held on June 14th, Sir W. Watson Cheyne, the President, being in the chair.—A report was read from the Board of Examiners in Anatomy and Physiology for the Fellowship, stating that at the recent examination 30 candidates were examined, and that of these 12 passed and 18 failed.—A report was read from the Court of Examiners stating that at the recent Final Fellowship Examination 12 candidates presented themselves, of whom 3 were approved and 9 were rejected. The Diploma of Fellow was accordingly conferred upon the following gentlemen who have complied with the necessary by-laws:—

Alberto Medardo Zumora, M.B. Cantab., M.R.C.S., L.R.C.P., Guy's Hospital; Lyle John Cameron, M.D. Manitoba, M.R.C.S., L.R.C.P., Manitoba University, London and Charing Cross Hospitals; and John Dudgeon Oliver, M.B. Dub., M.R.C.S., L.R.C.P., Dublin, and Middlesex Hospital.

Diplomas of Member were conferred upon the following two candidates who have complied with the necessary by-laws:—

Edward Thomas Holdge, M.B. Toronto, Toronto University and Middlesex Hospital; Eleanor Joyce Partridge, Royal Free Hospital.

Licences in Dental Surgery were also conferred upon 16 candidates who have passed the requisite examinations and have complied with the by-laws of the College. The following are the names and schools of the successful candidates:—

Hubert John Vere Raywood Allin, Birm'ngham University; Theodore Boques Barton, Guy's; Albert William Ewart Chapple, Manchester University; Reginald George Joseph Charlesworth, Middlesex and Royal Dental; Leslie Douglas Crabb, Guy's; Morgan James Evans, Birmingham University; George Frederick Faustmann and Frederick George Pritchard Flanders, Guy's; Sidney Francis Greenfield, Middlesex and National Dental; Wallace Inman, Middlesex and Royal Dental; Harold John Powell, Guy's; William John Ross, Liverpool University; Willem Gerrit Ryss, Middlesex and Royal Dental; Robert William Spong, Guy's; Sidney Stamp, Middlesex and Royal Dental; and Sydney Granville Townley, Guy's.

The Secretary reported the death of Mr. W. B. Kebble, clerk in the secretary's office, who had been in the service of the College since 1884.

The Council elected the following examiners. Examiners in Anatomy and Physiology for the Fellowship:—Anatomy: R. W. Reid, Gordon Taylor, William Wright, and W. H. Clayton Greene. Physiology: G. A. Buckmaster, J. B. Leathes, H. W. Lyle, and F. A. Bainbridge. The Examining Board in England: Elementary Biology: W. G. Ridewood and G. P. Mudge. Anatomy: J. E. S. Frazer, Arthur Thomson, and F. Wood Jones. Physiology: C. M. Hinds Howell and G. A. Buckmaster. Midwifery: H. Russell Andrews, C. H. Roberts, J. S. Fairbairn, and G. F. Darwall Smith. Public Health, Part I.: J. W. H. Eyre; Part II.: F. N. K. Menzies. Tropical Medicine and Hygiene:—Bacteriology: J. W. H. Eyre. Diseases of Tropics: C. W. Daniels.

A letter was read from Mr. H. J. Waring reporting the proceedings of the General Medical Council at their recent session, when the thanks of the Council were given to Mr. Waring for his services as the representative of the College.—The President reported that he had nominated Mr. Bilton Pollard to serve on a tribunal which has been set up by the Ministry of Pensions for the consideration of appeals by discharged disabled sailors and soldiers with reference to the grant of gratuities in place of pensions.—The President reported that a meeting of Fellows would be held on July 5th next for the election of three Fellows into the Council in the vacancies occasioned by the retirement in rotation of Mr. W. Harrison Cripps and Mr. C. Warren Low, C.B., and by the death of Sir Frederic Eve, and that the list of candidates was as follows: Mr. Cripps, Mr. Low, Mr. H. B. Robinson, Mr. H. B. Grimsdale, Mr. F. J. Steward, Mr. James Sherren, and Mr. P. W. Bassett-Smith.—The President reported that the terms of office as examiners for the College of Mr. L. A. Dunn and Mr. W. H. Dolamore would expire on July 25th, and that the vacancies would be filled at the ordinary meeting of the Council on July 26th.

ROYAL MEDICAL BENEVOLENT FUND.—The following are the details of cases of special distress caused by the war which the committee have helped from the War Emergency Fund:—

Lieutenant in the R.A.M.C. who had only been in practice a few years, volunteered for service and was killed in action a few days later. He left a widow with two children, aged 3½ years and 1 year, without means except the War Office pension. The Fund voted £25 for immediate necessities, and the Officers' Families Fund gave further help.—Captain in the Territorials was called out and had to leave his practice in the hands of a locum, who proved a failure. There were seven children, aged 2-14. Financial difficulties arose, and payment of the school fees became impossible. Between the Fund and Guild and the Officers' Families Fund the necessary fees were raised and sorely needed clothing provided.—Captain in the Territorials who was called out when the Army mobilised and had to leave his practice, worth £800, at a day's notice. Could not pay the fees for his son's education, who was in his last year at school. The Fund, the Guild, and the Professional Classes War Relief Council together raised the necessary money.—Captain in the Territorials was killed in action and left a widow and two children, aged 3 and 4½ years. The Fund investigated the case and referred it to the Officers' Families Fund, who granted a sum of money to meet immediate necessities. The Fund also obtained work for the widow, a trained nurse, who was thus enabled to earn her own living.—Major R.A.M.C., Territorial, was called out at the beginning of the war, and was abroad for over two years. He was invalided to England and put on home service. His practice was completely lost by his absence. There are three children, one in the Navy, one in the Army, and one at school. He had to give up his house, as he was in difficulties with rent, taxes, and education. The Fund gave £50, and further help was obtained from other sources.—Captain in the R.A.M.C. (T.), with a wife and six children; found the income derived from his practice, left in the charge of a locum, and the balance of his Army pay insufficient to meet his minimum expenses. He obtained assistance from the Civil Liabilities Committee and the Officers' Families Fund, and a grant was made from the War Emergency Fund towards the education of the children.—Practitioner, earning £700 to £800, volunteered for service, leaving his practice in the hands of a neighbour, who was not a success. There were two children, aged 7 and 10, and another baby was born shortly after the husband left. The wife contracted pneumonia and nearly died. A resident patient had to leave the house. Rent and other expenses led to a debt of about £80. This the doctor could not meet, and he hurried back from the trenches to save his home from being sold up. The Fund voted £25, the Guild gave £15, the Officers' Families Fund £25, and the Professional Classes War Relief Council offered further help, with the result that he returned to the Front with his immediate anxieties relieved.

Subscriptions may be sent to the acting honorary treasurer, Dr. Samuel West, at 11, Chandos-street, Cavendish-square, London, W. 1.

THE address of the National Council for Combating Venereal Diseases is now Avenue Chambers, Southampton-row, London, W.C. 1.

CONFERENCES ON VENEREAL DISEASES.—The second annual meeting of the National Council for Combating Venereal Diseases was held at the Queen's Hall, London, on June 13th, Lord Sydenham presiding. The latest information was given by Lord Rhondda regarding the council schemes for diagnosis and treatment. Out of a possible 145, schemes had been submitted by 102 councils (representing a population of 26 out of the total 36 millions), and of these 68 had been approved. In 52 hospitals, dealing with a population of 16 millions, work had already commenced in the treatment centres. Up to the end of May 6000 new cases were treated in the London clinics alone, and the centre at the Albert Dock Hospital was doing specially useful work in arresting cases of venereal diseases imported from abroad.—A conference took place at the beginning of the month under the auspices of the Public Health Committee of Edinburgh Town Council. Sir Malcolm Morris, chairman of the Propaganda Committee of the National Council, dealt in an exhaustive way with the legislation which enabled communities to deal with the diseases. The Edinburgh corporation are preparing a scheme in accordance.

SOCIETY FOR THE STUDY OF INEBRIETY.—The next meeting of this society will be held in the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W., on Tuesday, July 10th, at 4 P.M., when Dr. Stanley Kent, professor of physiology in the University of Bristol, will open a discussion on "Fatigue and Alcohol."

ROYAL VICTORIA HOSPITAL, BELFAST.—A committee of business men who have investigated the finances of the Royal Victoria Hospital, Belfast, have published a table contrasting the hospital with similar institutions in the United Kingdom, and from their figures it appears that in 1916 the cost per bed in the Royal Victoria Hospital was £80, which was only surpassed in smallness of amount by the Aberdeen Hospital (where it was £70), by the Hospital in Dundee (where it was £71), and by the Royal Infirmary, Edinburgh (where it was £76). The highest cost per bed was at the London Hospital, where for 1916 it was £143. In Birmingham it was £107, in Leicester £103, and in Cardiff £102. In the Royal Victoria Hospital the average beds occupied in 1916 were 277·6, instead of 266·8 in 1915, and the expenditure was £10 per bed higher.

RED CROSS GIFTS.—£100,000, the first instalment of the amount raised in Victoria in response to the appeal made by Lady Stanley, wife of the Governor, are being remitted to London for the British Red Cross.

Sir E. Cooper Perry has been elected Vice-Chancellor of the University of London for the ensuing year, as successor to Sir Alfred Pearce Gould.

ROYAL MEDICAL BENEVOLENT FUND OF IRELAND.—The annual meeting of the Royal Medical Benevolent Fund was held on June 14th at the Royal College of Physicians, Dr. J. F. O'Carroll, President of the College, presiding. The annual report stated that the number of applicants during the year had been large, and the amount recommended to be given in grants was greater than usual. The total amount of grants was £1239. The branch subscriptions showed a substantial improvement. Donations and bequests fell short by only £24. The income was £1629, showing a gratifying increase of £362.

SOUTH LONDON HOSPITAL FOR WOMEN.—The fifth annual report of this hospital, dealing with the year 1916, refers to the new buildings for in-patients opened in July last by the Queen, who has become patron of the hospital. In the October following two wards were available for patients, and by December 66 in-patients had been provided for. It is hoped that the remaining 14 beds will be ready as soon as the necessary nursing staff can be obtained. At a meeting recently held on behalf of the hospital Sir Alfred Keogh, Director-General of the Army Medical Service, said that the Local Government Board had recognised it as a treatment centre for venereal diseases, and he looked to the hospital to render great public service in the venereal campaign. Lady Londonderry said the accommodation of the hospital was far less than was needed both in the matter of beds and the treatment of out-patients. An increased nursing staff was a pressing need.

DONATIONS AND BEQUESTS.—By the will of the late Lieutenant-Colonel Sir John Howard, of Brighton, the testator has left £40,000 in trust to establish a "John Howard" Hospital, primarily for surgical cases, and for the use of patients able and willing to pay reasonable and ordinary fees, or to assist any existing hospital, or for other hospital purposes in Brighton; £33,000 and the land on which it is built for the "John Howard" Convalescent Home and for the erection of 24 cottages for the use and lodging of trained hospital nurses whose health has broken down, and for the payment of 10s. a week to each of the inmates; and £600 a year for 21 years for the "Howard Charity" for the relief of distressed widows and aged and sick poor of Brighton; £300 to the Sussex County Hospital; and £200 to St. Bernard's Home for Invalid Gentlewomen.—The late Mr. Arthur Edward Seawell, of Farnham, has left by will £300 to the Alton Cottage Hospital and £200 to the London Hospital.—Under the will of the late Mr. Henry William Ransom, of Folkestone, the Victoria Hospital, Folkestone, will receive £1000.

URBAN VITAL STATISTICS.

(Week ended June 16th, 1917.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 17,000,000 persons, the annual rate of mortality was 12·8, against 12·7 per 1000 in each of the two preceding weeks. In London, with a population exceeding 4,000,000 persons, the death-rate was 12·3, or 0·2 per 1000 above that recorded in the previous week; among the remaining towns the rates ranged from 3·7 in Grimsby, 4·7 in Wimbledon, and 5·2 in Swindon, to 20·9 in Hastings, 21·2 in Middlesbrough, and 26·2 in South Shields. The principal epidemic diseases caused 317 deaths, which corresponded to an annual rate of 1·0 per 1000, and included 195 from measles, 46 from infantile diarrhœa, 35 from whooping-cough, 28 from diphtheria, 10 from enteric fever, and 3 from scarlet fever. The deaths from measles were 13 below the number in the previous week, and caused the highest annual death-rates of 2·9 in Sunderland, 3·1 in West Bromwich, 4·1 in Walsall and in Rotherham, and 5·9 in Middlesbrough. The 601 cases of scarlet fever and 1089 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 35 below and 7 above the numbers remaining at the end of the previous week. Of the 4160 deaths from all causes in the 96 towns, 141 resulted from violence. The causes of 32 deaths were uncertified, of which 5 were registered in Birmingham and 5 in Liverpool.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual death-rate was equal to 14·7, against rates declining from 17·0 to 14·9 per 1000 in the four preceding weeks. The 335 deaths in Glasgow corresponded to an annual rate of 15·7 per 1000, and included 31 from measles, 29 from whooping-cough, and 1 each from diphtheria and infantile diarrhœa. The 85 deaths in Edinburgh were equal to an annual rate of 13·4 per 1000, and included 10 from measles, 6 from whooping cough, and 1 from scarlet fever.

Irish Towns.—The 136 deaths in Dublin corresponded to a rate of 17·8 per 1000, and included 3 from measles and 2 from infantile diarrhœa. The 117 deaths in Belfast were equal to a rate of 15·5 per 1000, and included 3 from infantile diarrhœa and 1 each from enteric fever, measles, and diphtheria.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Report of Mesopotamia Commission.

THE report of the Commission of Inquiry into Military Operations in Mesopotamia has been laid on the table of the House of Commons.

Chemistry at Edinburgh University.

An ordinance of the Edinburgh University Court respecting the foundation of a chair of Chemistry in relation to medicine has been presented to Parliament.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 13TH.

Treatment of Shell Shock.

Colonel YATE asked the Under Secretary for War whether permission could now be given for soldiers suffering from shell shock and other convalescents in hospitals and command depôts who were fit for light work to employ their leisure time, when they wished to do so, in agriculture, gardening, and the cultivation of any land there might be in the neighbourhood, so as to afford the men some relief from the monotony of their existence and give them an interest in life.—Mr. MACPHERSON replied: Soldiers in command depôts are already employed in the cultivation of land in and about the depôts. Arrangements have been made and are being extended by which men in hospital suffering from shell shock are employed on agricultural work as soon as they are fit for it. As regards other convalescents, the first concern of the Army authorities is to get men fit again as quickly as possible to resume military duty.

THURSDAY, JUNE 14TH.

Repatriation of Incapacitated Prisoners.

Mr. J. F. HOPE (representing the War Prisoners Department) informed Mr. MACMASTER that the Government had heard from the French Government that an extended agreement for the repatriation of French and German incapacitated combatant prisoners had been in force for a week, but he did not yet know the details. The only agreement in force between H.M. Government and the German Government for the repatriation of combatant prisoners of war was in respect of those who were totally incapacitated from further military service. It should be understood that this reply applied only to exchange of prisoners and not to internment in neutral countries.

Pensions for Officers and Nurses.

Replying to Sir H. CRAIK, Mr. BARNES (Pensions Minister) regretted that the new Warrant in regard to the pensions of officers and nurses had been delayed, but he thought that a satisfactory settlement was now in sight, and he hoped to lay the document before the House within the next fortnight. The beneficiaries would suffer no disadvantage, as payment under the new scales would operate as from April 1st.

Medical Re-examinations.

Answering Sir M. LEVY, Mr. MACPHERSON (Under Secretary for War) wrote: I am aware that attempts are being made to stir up dissatisfaction with the administration of the Military Service (Review of Exceptions) Act. There have been cases in which reasonable grounds for dissatisfaction have been present. In practically every case these grounds have been removed before any public comment arose. The whole administration is being, and will continue to be, most carefully watched, and throughout the country Medical Boards are working with great care. I am not aware that any man totally unfit for military service is being accepted for active service. If my honourable friend will supply me with details of the cases he has in mind they will be fully inquired into. Copies of all printed instructions issued in connexion with the Review of Exceptions Act are in the library of the House of Commons. No secret or oral instructions have been issued by the Army Council. With reference to alleged cases of disagreement between the classification shown on a man's medical history sheet and on his classification card, I have no knowledge. The proceeding is to attach to the medical history sheet a counterfoil of the classification card. This counterfoil is made out at the same time as the classification card received by the man. It, therefore, is unlikely that mistakes are made. If the honourable Member knows of any specific instance full inquiries will be made. The instructions dealing with this matter are in the library of the House. Figures as to the percentage of men rejected as totally unfit who on re-examination have been classified in categories A, B, and C are not yet available for the whole country, but in some localities the pe centage of A category men has been low. In one district notorious for fraudulent rejection in the past the percentage has been as high as 25 on the examinations conducted up to June 1st. All the suspected cases were called first in that area, and the result has been fully to substantiate the worst fears of the authorities. The boards conducting those examinations were composed entirely of civilian medical men with Territorial or temporarily commissioned or retired presidents. They have been specially inspected by inspectors from the War Office and their work has been reported as a model of careful examination.

R.A.M.C. Officers Training Centre.

Mr. MORRELL asked the Under Secretary for War whether he was aware that a large number of qualified surgeons and medical practitioners were undergoing a course of military training at Blackpool; whether many of these men had for weeks past been engaged all day on the usual infantry drill without the opportunity of doing any medical or surgical work of any kind whatever, although in many cases they were highly skilled men and had given up large practices in order to serve in the Army; whether a similar state of things existed in other training centres; and whether, in view of the need for doctors and surgeons at the front, he would take any steps in the matter.—Mr. MACPHERSON answered: Medical men are sent to Blackpool training centre for a short course of instruction, on the completion of which they are despatched to the forces abroad. All the officers other than the permanent staff of those temporarily unfit for service abroad are waiting opportunities for shipment. There is no other training centre for Royal Army Medical Corps officers.

Promotions of R.A.M.C. Officers.

Captain WRIGHT asked the Under Secretary for War whether Territorial officers of the Royal Army Medical Corps had recently been sent out to France in charge of branch Territorial hospitals with the rank of temporary major who were not Territorial officers before the war, or were not on the staff of a recognised Territorial hospital, and therefore not *à-la-suite* officers, whilst officers who were serving before the war, who had been mobilised since August, 1914, at the front since February, 1915, and in some cases officers commanding surgical division at general hospitals were held not to be eligible for promotion above the rank of captain; and why doctors who until recently had remained in the enjoyment of their practices in England were given advantages of promotion and pay over officers who had been voluntarily serving in His Majesty's Forces for years before, and continuously since, the beginning of the war.—Mr. MACPHERSON answered: I am not clear to which hospitals my honourable and gallant friend refers. If he has in mind the special Territorial general hospitals which were recently sent overseas, the senior officers were specially selected from the Territorial Force general hospitals in each command which furnished a hospital. These officers by a special arrangement were to serve for a minimum period of three months, and be relieved when necessary by other officers on the staff of the parent hospital. Appropriate acting rank was given to officers occupying positions where such promotion was considered desirable. The question of appointing field officers to the charge of the medical and surgical division of all general hospitals is under consideration.

Mr. MACVEAGH asked the honourable gentleman what principles, or basis of principles, now obtained for the selection of officers in the Royal Army Medical Corps for promotion in rank; whether the same principles for purposes of promotion held in the case of Royal Army Medical Corps officers in the Regular Force, the Territorial Force, and the temporary commissioned officers; whether any differences in the system of promotion existed in the different branches of the Royal Army Medical Corps; whether his attention had been called to certain recent promotions in the Territorial Force to the rank of major in the Royal Army Medical Corps; whether all or most of the officers so promoted had till quite recently been serving at home; whether he was aware that such promotion over the heads of other officers, some senior in previous and present service, in the same and other branches of the Royal Army Medical Corps who had had considerable overseas service was prejudicial to the interests of the medical service and was likely to increase the sense of injustice as to the irregularity of promotions, and that injustice had been done in some instances; and whether such promotions came within the purview of the recently appointed Army Promotions Board.—Mr. MACPHERSON wrote in reply: Promotions in the Royal Army Medical Corps, Regular, Special Service, and Territorial Force, up to the rank of major are governed by a qualifying time period of service for each step in rank. Promotions above the rank of major are by seniority and selection. In the case of a temporary commissioned officer promotion to captain is given after 12 months' service and promotions to higher rank are given in individual cases as suitable vacancies arise according to the officer's qualifications and

the nature of the appointment for which such promotion is considered necessary. No differences other than those enumerated exist in the system of promotion in the different branches of the Royal Army Medical Corps. If my honourable friend is referring in the latter part of the question to promotions made in the Special Territorial Force general hospitals, which were recently sent to France under special conditions to meet emergency, the promotions made in these units are all temporary and are not considered as prejudicial to the interests of the medical service or as causing injustice to other officers. The whole question of promotion generally in the Royal Army Medical Corps Territorial Force comes within the purview of the committee presided over by the Member for Dundee (Mr. Churchill).

Sir E. GOULDING asked when the report of the committee which had considered and reported on the question of promotion in regard to the General Reserve of Officers, the Special Reserve of Officers, and of the Territorial Force would be laid upon the table.—Mr. MACPHERSON replied: The recommendations of this committee are being sympathetically considered, and as soon as final decisions have been reached in regard to them the report will be presented to both Houses together with a note of the decisions. I trust this will be done very shortly.

Medical Students and Military Service.

Mr. DILLON asked the Under Secretary for War whether, in view of the increasing demands by the War Office on the medical profession and the great number of casualties amongst doctors in the field, the War Office would exempt all medical students of one year's standing and upwards from liability to be called up under the Military Service Acts.—Mr. MACPHERSON wrote in reply: The Army Council has been in close touch with the medical authorities, and the need for providing for future needs of the medical profession has been given full weight. Under present arrangements a large measure of protection is given to medical students. None of those who are within 24 months of qualification are called up for service, while of those in the earlier years only men fit for general service or classified B 1 are called up. In view of the present need of men of those categories for combatant service it is not considered that in the national interest any alteration of the present arrangement should be made.

MONDAY, JUNE 18TH.

The Case of Dr. J. C. M'Callum.

Mr. T. E. HARVEY asked the Home Secretary whether Dr. J. C. M'Callum, a graduate of Edinburgh University, medallist and holder of the Mouat scholarship, executive tuberculosis officer for the county of Argyll, holding the diploma of public health, and having specialised in the treatment of tuberculosis, had been employed by the Home Office Committee on Employment of Conscientious Objectors, first at Wakefield and then as a labourer in the manufacture of manure for Messrs. Rough and Sons, Broxburn, Edinburgh; whether, in consequence of a breach of workshop discipline, this employment had been terminated; and whether, in the national interest, he would consider the possibility of employing this specialist on public health work under whatever financial conditions the committee's regulations imposed instead of on work for which he was not fitted or instead of sending him back to court-martial and prison.—Sir G. CAVE replied: John M'Callum has been employed as stated. His employment has been terminated, not for one but for several breaches of discipline. The Committee on the Employment of Conscientious Objectors have recommended his recall to the Army, and the case is now out of their hands. I understand that Dr. M'Callum has never applied to the Committee to be released in order to take up employment as a doctor, but he and members of his family have made applications for him to be allowed to do ploughing and similar work for relatives.

Mr. HARVEY: Will the right honourable gentleman consider that this Committee should employ doctors for medical work in view of the great need for doctors in this country?—Sir G. CAVE: If applications were made for their services no doubt they would be considered.

American Medical Men.

Replying to Sir G. GREENWOOD, Mr. MACPHERSON (Under Secretary for War) said: We only propose to accept the services of American doctors sent to us by responsible authorities in the United States.

Surgical Aid in Air Raids.

Mr. BROOKES asked the Home Secretary whether, on the occasion of the recent air raid, one of the leading hospitals had to request the services of an entire Army Medical Board; and whether arrangements existed for ensuring prompt and adequate surgical aid in all cases.—Sir G. CAVE wrote in reply: Arrangements are made by the police for securing the services of doctors and ambulances and making other provisions for rendering first aid. I understand that on Wednesday last, owing to the short time which elapsed between the receipt of warning by the police and the occurrence of the raid, medical aid was urgently required, and the services of the members of an Army Medical Board were requisitioned.

TUESDAY, JUNE 19TH.

A Ministry of Health.

Sir W. COLLINS asked the Chancellor of the Exchequer whether any decision had been arrived at by the Government as to the establishment of a Ministry of Health.—Mr. BONAR LAW replied: I am not yet in a position to make any statement.

Sir W. COLLINS: Are we to understand that the statement published yesterday on the authority of the President of the Local Government Board to the effect that a Ministry of Health is about to be established is incorrect?—Mr. BONAR LAW: I have not noticed that. I know that my noble friend has been working on the subject, but the Government has come to no decision, and it is not possible to introduce legislation this session.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

BOYCE, C. R., F.R.C.S. Irel., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Enniscorthy District of the County of Wexford.

LUCAS, C. B., L.R.C.P. & S. Edin., L.F.P.S.G., Certifying Surgeon under the Factory and Workshop Acts for the Fovers District of the County of Invernesa.

WOOD-SMITH, ALGERNON, M.D., F.R.F.P.S.G., School Medical Inspector to the County of Stirling.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

BELGRAVE HOSPITAL FOR CHILDREN, Clapham-road, S.W.—Resident Medical Officer for six months. Salary at rate of £75 per annum, with board, &c.

BIRMINGHAM.—Female Locum Tenens for Infant Consultation Work for three months. Salary 8 guineas per week.

BODMIN, CORNWALL COUNTY ASYLUM.—Female Junior Assistant Medical Officer. Salary £200 per annum, with board, &c.

BRISTOL ROYAL INFIRMARY.—House Physician and House Surgeon. Salary at rate of £120 per annum, with board, &c.

CARDIFF, KING EDWARD VII.'S HOSPITAL.—House Surgeon for six months. Salary at rate of £200 per annum, with board, &c.

CHELSEA HOSPITAL FOR WOMEN, Arthur-street, Chelsea, S.W.—Resident House Surgeon and Registrar for 12 months. Salary £150 per annum.

DEVONPORT, ROYAL ALBERT HOSPITAL.—House Surgeon, unmarried. Salary £150 per annum, with board, &c.

DONNYBROOK, DUBLIN, ROYAL HOSPITAL FOR INCURABLES.—Resident Medical Officer, unmarried. Salary £200 per annum, with board, &c.

EAST LONDON HOSPITAL FOR CHILDREN, Shadwell, E.—Assistant Resident Medical Officer. Salary £125 per annum, with board, &c.

ENFIELD, ROYAL SMALL ARMS FACTORY.—Assistant Medical Officer. Salary £438 per annum.

EVELINA HOSPITAL FOR CHILDREN, Southwark, S.E.—House Physician. Salary at rate of £160 per annum, with board, &c. Also Clinical Assistants in Out-patient Departments.

GENERAL LYING-IN HOSPITAL, York-road, S.E.—Resident Medical Officer for three months. Salary £100 per annum, with board.

GLOUCESTERSHIRE ROYAL INFIRMARY AND EYE INSTITUTION.—Assistant House Surgeon. Salary £150 per annum, with board, &c.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—House Surgeon. Salary £250 per annum, with board, &c.

HAMPSTEAD GENERAL HOSPITAL, Haverstock Hill.—Resident House Physician for six months. Salary at rate of £200 per annum.

LEEDS GENERAL INFIRMARY.—Resident Aural Officer. Salary £100 per annum, with board, &c.

LEICESTERSHIRE EDUCATION COMMITTEE.—Temporary Assistant School Medical Officers. Salary at rate of £350 per annum.

MANCHESTER AND SALFORD LOCK HOSPITAL.—Temporary Part-time Medical Officer. Salary £300 per annum.

MANCHESTER CHILDREN'S HOSPITAL, Pendlebury, near Manchester.—Two Female Resident Medical Officers, unmarried. Salary at rate of £200 per annum.

MANCHESTER COUNTY ASYLUM, Prestwich.—Locum Tenens. Salary £7 7s. per week, with board, &c.

NOTTINGHAM GENERAL HOSPITAL.—Holiday Locum Tenens, Female. Salary at rate of £250 per annum, with board, &c.

OLDHAM ROYAL INFIRMARY.—Third House Surgeon. Salary £225 per annum, with board, &c.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—House Physician. Salary £200 per annum, with board, &c.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Assistant Resident Medical Officer for four months. Salary at rate of £60 per annum, with board, &c. Also District Resident Medical Officer for four months. Salary at rate of £60 per annum, with board, &c.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—House Physician for six months. Salary £100 per annum, with board, &c.

ROTHERHAM HOSPITAL.—Junior House Surgeon. Salary £150 per annum, with board, &c.
ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C.—Third House Surgeon. Salary at rate of £50 per annum, with board, &c.
SALFORD ROYAL HOSPITAL.—Junior House Surgeon. Salary at rate of £150 per annum, with board, &c.
SHEFFIELD ROYAL INFIRMARY.—House Physician. Salary £120 per annum, with board, &c.
SHEFFIELD UNION HOSPITAL, Firvale.—Female Resident Assistant Medical Officer. Salary £250 per annum, with rations, &c.
SHREWSBURY, ROYAL SALOP INFIRMARY.—House Physician. Salary at rate of £200 per annum, with board, &c.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Raunds, Northampton; Rosscarbery, Cork; and Tattenhall, Chester.

Births, Marriages, and Deaths.

BIRTHS.

BASHFORD.—On June 18th, at Downshire-hill, Hampstead, the wife of H. H. Bashford, M.D., of a daughter.
EDRIDGE.—On June 10th, to Dr. and Mrs. Ray Edridge, of Lynvale, St. Mark's-place, Bath, of a son.
HILL.—On June 18th, at Armaside, Purley, the wife of Lieutenant R. Gordon Hill, R.A.M.C., of a daughter.
HUGHES.—On June 9th, at Tudor House, High Barnet, the wife of Lieutenant G. R. Hughes, R.A.M.C., of a daughter.
MELLAND.—On June 13th, at Ladybarn-road, Fallowfield, Manchester, the wife of Dr. Charles H. Melland, Captain, R.A.M.C.(T.F.), of a daughter.
MUSGRAVE WOODMAN.—On June 10th, at Newhall street, Birmingham, the wife of Captain B. Musgrave Woodman, R.A.M.C., of a son.
STADDON.—On June 13th, at King's-road, Kingston-on-Thames, the wife of Captain Eric J. Staddon, R.A.M.C., of a son.

MARRIAGES.

HOBBS—CARGILL.—On Tuesday, June 12th, at St. Saviour's, Warwick-avenue, W., Surgeon Roland A. Hobbs, R.N., to Marjorie, elder daughter of Mr. Justice and Mrs. Cargill, of Kingston, Jamaica.
MCLEAY—PEIRS.—On June 18th, at the Parish Church, Carshalton, Charles Wm. McLeay, M.D., W.A.M.S., to Olive, youngest daughter of Hugh Vaughan Peirs.

DEATHS.

FRERE.—Killed in action, "while attending the wounded near the front line," on June 9th, his 27th birthday, Captain Frederick John Henry Tob'as (Eric) Frere, M.C., M.B., R.A.M.C., attached Lincoln Regiment.
HAIRSINE.—Killed in action, on June 9th, Captain Owen Hairsine, M.C., R.A.M.C., aged 26.
WALTERS.—On June 11th, at More Cottage, Reigate, John Walters, M.B., J.P., in his 81st year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE DISPOSAL OF THE DEAD.

THE manner of burial or disposal of the dead human body is a subject of perennial interest to the public at large, to each individual, and to the sanitary authorities. The Burial Act of 1855 enacts that no burial shall take place within 100 yards of a dwelling-house, and this decision is undoubtedly for sanitary reasons. It is necessarily affected by the kind of coffin in which the body is buried. Economy in burials, as in other things affecting private affairs, is now the order of the day. The cost of funerals and coffins has often been entirely out of proportion to the status of the deceased and absorbing most of the insurance money. Transporting bodies long distances is often a matter of sentiment and must to-day be discouraged.

Apart from ordinary coffins, there have been the simple winding-sheet or shroud, a blanket, papier maché, bark, the hollowed trunk of a tree, or a wicker basket with charcoal. Limestone, other kinds of stone, marble, and iron have all been used for coffins, and there is a beautiful alabaster sarcophagus of Seti, father of Rameses II., amongst the art treasures in Sir John Soane's Museum in Lincoln's Inn Fields. The coffin as a work of art has frequently appealed to oriental nations, who have often had them made perhaps years before death, a practice not unknown in European countries. Some old coffins were superbly enamelled and jewelled with fragments of precious stones and gilded with real gold. Sir Erasmus Wilson said that sometimes copper was fraudulently used instead of gold by the ancient Egyptian artists. Some years ago there was an attempt to introduce general burial of the body by pouring lime in the wooden coffin just before interment, but the idea did not recommend itself to æsthetic tastes or religious sentiment. As compromises wicker coffins or alternately coffins with thin glass lids, so that the weight of the earth should quickly smash in the lid and expedite the dissolution of the body, were recommended. The majority of people in this country, however, still adhere to lead, oak, and elm coffins with brass handles and nameplate. In the United States the glass lid coffin seems to be growing in vogue, although there a coffin is usually called a "casket." The casket may be made of bronze, cast metal, or steel, and claims to protect the bodies "from the hideous violations of the earth."

The disposal of the bodies of certain of the American Presidents forms an example which hygienists will regret. There is at Canton, Ohio, a McKinley monument, and in this tomb lie the remains of President McKinley and his wife in Springfield metallic caskets of bronze. These caskets were patented in the United States in 1898, and are claimed to be "the most perfect burial receptacle known." The adherents of burial reform who advocate that dissolution should take place as rapidly as possible and that no built graves should be used will hardly be likely to agree to this claim. President Garfield was buried in a bronze casket in 1881, and President Grant, who died in 1885, was buried in a casket of Bessemer steel with oval top, secured by rivets put in red hot. It is 8 feet long, 3 feet 6 inches high, and 35 inches wide, painted with waterproof paint, and stained mahogany colour. Its gross weight is 3800 lb. It has silver mountings and a gold plate engraved with his name, "U. S. Grant." It is claimed to be burglar-, air- and fire-proof. President Lincoln was first buried in a red cedar coffin, but an attempt was made to steal the body and it is now covered by a huge monument. The large number of men killed in the present war has caused a reversion to primitive methods of burial—nature's barrows and tumuli or crevasses which call for no coffins.

INDIAN AMBULANCE MANUALS.

FROM Messrs. Vithal Asharam Thakkar, Shiyapura-Baroda, we have received a copy of "Prathmic Madad Karanaraone Shikshan," a translation of Colonel R. J. Blackham's little book on Indian ambulance training, which has been made in Gujerati by Dr. Dhanjibhai Hormasji Mehta, lecturer and examiner to the St. John Ambulance Association, and jail superintendent at Baroda. The price is 1 rupee. The author, who has done his work in a very careful and painstaking manner, is an enthusiastic ambulance worker, and has translated for the use of Hindoos and others several ambulance and first-aid books, including "Tropical Hygiene," by Sir Pardey Lukis and Colonel Blackham. The translation of "Indian Ambulance Training" should prove useful to ambulance centres in Gujerati and Kathiawar, especially in the formation of classes for instruction in

receiving the wounded from the Front. Messrs. Claridge and Co., Caxton House, Bombay, publish the original edition of "Indian Ambulance Training" in English, price 12 annas. This firm has also recently issued new editions of other ambulance books by Colonel Blackham—namely, "The Indian Manual of First Aid," fifteenth edition, price 1 rupee, and "A Primer of Tropical Hygiene," third edition, price 12 annas.

BANTING AND *PUNCH*.

THE aurist of distinction who first gave William Banting the hints as to diet which reduced his weight by two and a half stone[1] was Mr. William Harvey, of Soho-square. Writing to his brother Tom in 1863, William describes him as "oldish," but "A 1." The letter, with others, formed part of the grangerised "Comments on Corpulency [and] Lineaments of Leanness," by W. Wadd, surgeon extraordinary to George IV., which was knocked down for £40 at the recent Broadley book-sale at Messrs. Hodgson's. The book should have gone to a large medical library. William Banting was an unconscious humorist and the cause of wit in others. He refers to his obesity in his quaint pamphlet as "the parasite of barnacles on a ship. If it did not destroy the structure, it obstructed its fair, comfortable progress in the path of life."

Punch began on "Banting" in 1864. According to his nautical metaphor, Mr. Banting had been in dock 20 times, but had effected no repairs till he came under Mr. William Harvey, F.R.C.S. *Punch* sings as follows:—

> Some glutton has stated that brave Mr. Banting
> Himself has succumbed to the system he taught.
> 'Tis false, and he lives, neither puffing nor panting,
> But down to a hundred and fifty pounds brought.
>
> He's done it, and so may each overfed nigger
> Who'll simply adopt resolution severe
> To avoid, if he wouldn't grow bigger and b'gger,
> All bread, butter, sugar, milk, taters, and beer.
>
> Take a fresh lease of life and commence a new era,
> Mr. Banting's advice makes one long to begin—
> "Drink claret and sherry, good grog, and Madeira,
> Take four meals a day and—grow gracefully thin."

Such is "The Banting Code." On another page we have "The Banting Restaurant Joint Stock Company (Limited)."

> "This will devote its earnest attention to the preparation of viands which, whilst excluding, as much as possible, saccharine, farinaceous, and oleaginous matters, shall nevertheless administer, in the highest degree compatible with the absence of those savoury substances, to the pleasures of the palate."

The humour of mere corpulence abounds in the *Punch* of 1864–65, but obesity is apparently always regarded as a result of over-eating; pathological obesity, such as Daniel Lambert suffered from, is not recognised.

INTRUDING ANTS.

To the Editor of THE LANCET.

SIR,—Recently I have heard many complaints concerning ants (sometimes called emmets, pismires, &c., in the country) getting into larders, pantries, and food-cupboards. Perhaps the prolonged drought has left them free to multiply. Latterly I was puzzled to know how ants got into the house, but accidentally discovered one means. The portable dust-bin used to stand on concrete, but some weeks ago was placed on earth in the corner of the garden. The ants had made a "hill" underneath it, and when the dustbin was carried through the house to the front roadway for the periodical removal by dustmen, the ants clung unseen to the bottom of the dustbin, which, being heavy, was put down half-way through the house. Then some of the ants scampered around unseen inside the house. They find their way without much delay to the food-cupboards and pantries.

I have read of mixtures of paraffin and benzoline in equal parts, and of a mixture of snuff and powdered black hellebore. I know that many people pour plain paraffin on the tracks outside the house, lay about sticks of firewood soaked in creosote and paint places with carbolic acid inside the house, but these methods are not pleasant to use near food. Perhaps there are other methods. The above are at least 30 years old. Of course I know one can always kill them individually, but it is tedious work.

I am, Sir, yours faithfully,

London, June 18th, 1917. R. T.

*** The following are popular remedies: Powdered cloves with borax (oil of cloves thinned with methylated spirit could be worked up with the borax), or camphor 1oz. with borax 1 lb. Turpentine is a well-known and efficacious remedy, but not pleasant for food-cupboards.—ED. L.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY.—5 P.M., Croonian Lectures:—Lieut.-Col. J. G. Adami, A.D.M.S.: Adaptation and Disease. (Lectures IV.)

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patients (Mr. B. Gillespie). 2.30 P.M., Medical Out-patients (Dr. T. R. Whipham): Gynæcological Out-patients (Dr. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

TUESDAY.—2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. Howell Evans); Nose, Throat, and Ear Out-patients (Mr. C. H. Hayton). Radiography (Dr. Metcalfe). 3.30 P.M., Medical In-patients (Dr. A. J. Whiting).

WEDNESDAY.—Clinics:—2.30 P.M., Throat Operations (Mr. C. H. Hayton). Children Out-patients (Dr. T. R. Whipham); Eye Out-patients (Mr. R. P. Brooks); Skin Out-patients (Dr. H. W. Barber). 5.30 P.M., Eye Operations (Mr. R. P. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patients (Dr. A. J. Whiting); Surgical Out-patients (Mr. Carson); Radiography (Dr. Metcalfe). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

FRIDAY.—2.30 P.M., Surgical Operations (Mr. Howell Evans). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. B. Gillespie); Eye Out-patients (Mr. R. P. Brooks).

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

ROYAL INSTITUTE OF PUBLIC HEALTH, Lecture Hall of the Institute, 37, Russell-square, W.C. 1.

Course of Lectures and Discussions on Public Health Problems under War and After-war Conditions:—

WEDNESDAY.—4 P.M., Lecture XI.:—Major Sir William Milligan, M.D.: The Value and Importance of Physical Exercises from a National Standpoint. Followed by a discussion.

The following journals, magazines, &c. have been received:—Canadian Journal of Medicine and Surgery, Journal of Laryngology, Rhinology, and Otology, Revue de Chirurgie, Saint Paul Medical Journal, Journal of the Royal Sanitary Institute, Indian Medical Gazette, Journal of Nervous and Mental Disease, British Dental Journal.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.*

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

Offices: **423, STRAND, LONDON, W.C. 2.**

MANAGER'S NOTICES.

ALTERATION IN THE PRICE OF "THE LANCET."

INCREASED war expenses and cost of production necessitate an increase of the price of THE LANCET. Commencing with the new year, the price was raised to 8d. The rates of subscription remain as revised in October.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C. 2, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION is published in time to catch the weekly Friday mails to all parts of the world.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given on page 4.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied.

NEWSPAPERS FOR NEUTRAL COUNTRIES.

Newspapers are not at present being sent forward to neutral European countries unless posted direct from the office of publishers or newsagents who have obtained permission from the War Office for this purpose. The Publisher of THE LANCET has obtained the required permission, and he will forward copies direct from the Office to any neutral country on receipt of instructions.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, June 20th, 1917.

The Cavendish Lecture

ON

A DAY'S WORK.

Delivered before the West London Medico-Chirurgical Society on June 22nd, 1917,

BY ANDREW MACPHAIL, B.A., M.D., M.R.C.S.,

CAPTAIN, CANADIAN ARMY MEDICAL CORPS; PROFESSOR OF THE HISTORY OF MEDICINE, MCGILL UNIVERSITY, MONTREAL.

MR. PRESIDENT AND GENTLEMEN,—"The Canadian Corps is ordered to take the Vimy Ridge." So ran the official order. Never was an order obeyed with greater alacrity or executed with more complete success. This task was set in January; it was performed on Easter Monday. It is of that day's work I propose to speak.

But, first, I take leave to assure you that I am fully sensible of this high honour—an honour which is shared by all who come from overseas: addressing an audience such as this from a foundation so famous as the Cavendish, made still more famous by the long line of my predecessors in this office.

As I scan the roll three persons arise before me with singular clearness: Jonathan Hutchinson, who first directed my young feet—they were young in those days, although they have since made many a weary step—towards the London Hospital, where I learned the master truth that nothing pertaining to humanity is alien to the practice of medicine. It was in his company on the hills of Surrey I first heard the lark sing as it sang that day over the trenches in Artois. Next on the roll is Frederick Treves, from whom I learned the purity of surgery—for in those days surgical cleanliness was quite new; and, last of all, William Osler, who gave to medicine in the New World a fresh direction and an upward turn.

There was a time when even in such company as this I should have felt no embarrassment, for the professor's gown had been familiar to me, and I was accustomed to the use and even the embroidery of words. But I have long since abandoned the way of letters, and left that no-man's-land of ambiguity, where jest and earnest meet. Fresh, now, from a life of reticence, in which yea is yea, and nay nay, I listen with alarm to the sound of my own voice.

Nor do I fail to remind myself that this is a scientific assemblage accustomed on such occasions to the precision and austerity of science. Far from laboratories and books, concerned, for the most part, with horses and men, content with a hasty guess at diagnosis, and practising the rough surgery of the field I am fully aware that to-night I am doing deliberate violence to that long tradition of science which has made the Cavendish lecture sacrosanct.

THE SCIENTIFIC SPIRIT.

But, having embarked upon this new adventure, I shall be bold, and look even Science in the face. We are at war not alone with flesh and blood, but with principalities and powers. One of the principalities and powers with which we are at war is that unmitigated scientific spirit which is the peculiar possession of the enemy and is, happily, alien to our race.

That spirit is not our inheritance, yet none have done more than we for the advancement of real science, including the ancillary science of medicine and all sound learning. When I practised the trade of Professor of the History of Medicine I always regarded Sydenham as the great exponent of our method: "I take the view," he said, "that we shall go without any hypothesis, and study the conditions as they appear—the process before the explanation."

Upon many occasions I have developed that theme, but such is not my task to-night. Yet I cannot refrain from reminding you of an example, because it is the most recent, the work of James Mackenzie, who, by 20 years of quiet, patient observation set at naught the meretricious theory of the German upon the action of the heart. The German works in science as he works in war. He loves the underground. He throws out saps; he lives and moves and has his being in the darkness, when suddenly the free English spirit comes over the top in the full light of day.

Science with us is only a part of Life and a development from it. Our medicine is but a closer definition of what our fathers knew. The snake in India, the brazen serpent in the wilderness, the cat in Egypt—these sacred emblems indicate that those ancient peoples understood the genesis of "plague." This badge of maple leaves which I wear is copied boldly from a Roman coin, struck to commemorate the discovery that malaria can be mastered by draining the land and planting trees.

Let us grant to the uttermost that the pursuit of science is the pursuit of truth. The German cares nothing for the pursuit; he is all for the result, unaware that any given truth by itself is half a lie. There is the truth of the soldier, which is courage; the truth of the artist, which is beauty; the truth of the woman, which is virtue. The German believes that he has attained to all truth when he has discovered only a partial truth, forgetting that God alone is Truth, and that no man has looked upon God and lived. A lie which is only half a lie is far less deadly than a partial truth which is believed to be the whole truth.

Even to science the scientific spirit is fatal. It becomes dogmatic and then sterile. We have always kept in mind that there is a spiritual law in the natural world, whilst the German, lacking a philosophy of life, takes what he filches, and develops it in the cold void of abstract science. That is the genesis of his superman, a monstrosity developed from the tentative hypothesis of our own Darwin. Nay, more, the scientific spirit is the enemy of life. We live not by truth but by illusion, and the human heart creates those illusions which alone make life tolerable. There is a profound instinct which impels us to war against the truth, against reality. We eschew the fact, and take refuge in evasion. From the facts of life we fly to hope. The human race has nourished itself upon fiction, myth, and miracle. It still finds its fulfilment not in life but in immortality, not in formulæ but in religion.

The strength of the English race lies in its capacity to live and move in the realm of illusion, of poetry, whereby it discovers the higher truth and enters into the realm of emotion. The German, on the other hand, has deliberately shut himself out from this realm. As a consequence he sees darkly, judges falsely, fatally. He cuts himself off from the tree of life, and by becoming a scientist—"falsely so-called," as the Apostle is careful to specify—is become a beast without a background. One of your own has said it. We may then depart with some freedom, this year at least, from the tradition, and look at a common day's work.

THE SCENE OF ACTION.

I have selected as a text this day's work merely because by a piece of good fortune it fell to our division to act as the point of the spear. Two Scottish divisions held one flank, and many a man went forward with a lighter heart on that account. The 13th Brigade—of an English Division—went over with us, those wondrous English soldiers who work in a rage and then fall into silence. Down Arras way the Australians were working, those handsome soldiers who will not hold back. When they get a free road to Berlin there will be such doings as the Seer never saw from Patmos. Our comrades from South Africa and from New Zealand were engaged elsewhere, as all the world has since learned.

It would be a misuse of the occasion and a mis-spending of this short hour to attempt a description in detail of that day's work. The result would be merely a piece of journalism. No description can make intelligible the events which happen in the operating-room or the lying-in ward, and there are many subjects over which it is proper to draw the veil. I should merely mislead you. The task can only be performed by an artist with time and space for selection. By an infinity of small things he would create a picture. He would make you see a long cliff, extending for 20 miles from the north-west to the south-east, in shape like a dog's hind leg, with the Souchez river breaking through at the joint. He would lead you up the landward slope, over ridges and valleys, until you came to the summit. He would guide across a high plateau, and from the edge you would look down upon the old sea which is now the French Flanders plain, with its red villages and green fields. This is the Vimy Ridge, which rises from Souchez and slopes down to Arras.

You should know also that it was on this very spot, and upon the Lorette Ridge, which is the twin ridge to the north, across the Souchez river, that the French made their supreme offensive in 1915. Here was the Labyrinth—

Souchez, Neuville St. Vaast, Ablain St. Nazaire, La Targette, and Aux Rietz—where rifles were discarded and knives served out in their stead. Upon these heights lie 60,000 of their noble dead in fields of crosses which extend as wide as a forest. At the time we were somewhat insensible to this great struggle.

More than 18 months had passed, until on that April morning the business of the Canadian Corps was to pivot upon its left flank, and drive the enemy into this old sea bottom, which was done according to schedule in 468 minutes. I say minutes, because the plans were drawn as rigidly as that, and they were drawn in as fine detail as an architect would employ for the building of a house. For three months we worked upon those plans with as much care as one would bestow upon a performance on a stage. The humblest actor had his rôle, and he was ready against the hour when the curtain should rise.

A DIVISION: ORGANISATION AND LIFE IN THE TRENCHES.

An army is an extremely simple affair. It is composed of divisions, each one of which is self-contained, and has a staff with several branches. One branch deals with operations; another has to do with the persons who are to carry out those operations; a third is concerned with the housekeeping, by which all are clothed, housed, fed, and cared for in sickness and wounds. It is with this branch the medical service is identified. To each man it appears that he alone is carrying on the war, and in a sense he is. If he fails, something else goes wrong until all may be in jeopardy. In the end some single man in an army, like a housemaid in a house, has to do any given piece of work. I shall offer you an illustration. There is no water on the Ridge, and men need water. It was the business of a housemaid—he was really a staff major—to provide water. In the winter he began collecting petrol tins, and many a night I have heard him adjuring marauders to leave them untouched. To make quite sure, he had them stored behind his own hut until he had accumulated a pile as big as a church. One by one he had them burned out. He had special pack-saddles made to accommodate six tins. He filled these tins with sterilised water and had them loaded on mules. The pack-train was ready before the battle began, and the men drank water in the hour of their need. It was by no accident the Vimy Ridge was won. It was carried by the same methodical process by which a piece of land is farmed, a dinner party made a success, or a stage performance a triumph.

It is difficult, too, for you to appreciate how small is the battle area occupied by a division. It measured in this case 2000 yards in depth with a frontage of 1000 yards—about the size of a nice farm. This area was approached only by night or in fog, though ambulances and persons singly on foot might take a chance. Once the area is entered all life is underground. The road from Arras to Bethune runs at the rear, and the ground slopes gently upwards to the ominous crest of the flat-topped, gloomy Ridge. Through the bank by this road four trenches enter: two for going up, two for coming down. These trenches are joined by laterals according to the configuration of the ground, and one must learn his way about as a worm would learn his particular cheese. It is all very mysterious at first, but in time becomes as familiar as the streets of London. To cover the whole ground required a full day, and in clear, dry weather no exercise could be more pleasant, the trench floors clean, the walls defending from the wind, a strip of sky overhead, and it might be the voice of a lark against the background of noise.

It was a bitter winter there, as here. The soil was frozen to a depth of 14 inches. Rain fell. There was little drainage. The earth slid in on top of the water, and was trodden into a mess like dough. To walk the trenches under such circumstances is the last test of human endurance. On earth one can walk; through water one can swim; but progress can only be made inch by inch when earth and water are mixed in due proportion. One wears rubber boots hip-high, and from the tops a strap is fastened over the shoulders to prevent the boots being pulled off by the mud. On one occasion my orderly lost boots and socks, and came in with bare feet. If a man falls he may be lifted over the parapet, and left there till night; or he may lie where he fell, and be trampled under foot. It requires very little resolution to die: life is so hard, and death so easeful.

MEDICAL ARRANGEMENTS.

When we took over early in February our business was to devise medical arrangements in accordance with the battle plan, by which casualties should be removed to a main dressing station on their way to railhead. No one system will suit all engagements, and the system must be devised in view of defeat as well as of victory. Happily our labour was largely wasted, since the advance was so rapid that our underground fortress dressing stations were not urgently required. This was especially hard on the man who laboured all winter at the construction of the posts. One officer almost wept with grief when he saw our troops storming overland rather than make their way through a series of tunnels to which he had devoted a year in constructing. In this area we spent two months excavating ten dug outs, commodious as this room, 20 feet below the surface, shoring the roofs and walls, and fitting the place with racks for stretchers. Nearly all this work was done by the medical personnel under the supervision of a sapper. Remember, too, that the work could only be carried on by night, in fog, or in quiet intervals during the day, and that every stick had to be carried through such trenches as I have described.

Regimental aid-posts and field ambulance relay posts were parts of a system which ended at the rear of the battle area where a huge advanced dressing station was partly excavated and partly built. Two tram-lines had been thrust up by night on either flank to be used for sending ammunition and rations up, and they were of great service in bringing casualties down.

Let us now attempt to follow the progress of a wounded man. When he falls he is attended by the regimental medical orderlies and is sent back a few hundred yards by regimental bearers to the aid-post, where he is more carefully dressed by the regimental medical officer. There he is handed over to the field ambulance bearers and borne by hand, by wheeled stretcher, or by trolley from one relay post to another until, finally, at a distance of one or two miles he arrives at the advanced dressing station. There the dressings are examined and, if necessary, renewed. Trains of trolleys drawn by gasoline engines are in waiting to bear the loads farther to the rear, where they may be accessible to the motor ambulance convoy, which takes them to the main dressing station. Here the cases are re-dressed and so sent on to railhead, clean, warm, and fed.

Of the wounded in detail one sees little; one sees them in the mass. Our business is to speed them on their way, and 12 surgeons in a dressing station, working night and day, will clear the casualties as fast as they are brought in. The walking cases went direct from the field to collecting points and were sent down in 'buses, 40 at a load. The lying cases neither move, nor speak, nor utter a sound. It is only when we go to the base or come to England that we see the wreck of war and the pity of it all.

I cannot insist too strongly that medical arrangements must be devised anew for each action; they vary with the plan of battle, and must be modified as the battle proceeds. On the day in question an ample supply of blankets was assembled, but in the night a bitter wind arose, with wet driving snow. Within an hour 600 additional blankets were at the front, assembled and transported—it does not matter how.

Zero hour was at the dawn of a bleak morning. By 6 o'clock the wounded were coming in; by 7 the prisoners were marching down by companies; by 8 the supply trains were moving up, and by 9 o'clock the whole world was alive with men and horses and motors over roads that were spewing up their stony entrails. When the action was over the battle area was like a heavy cross-sea which had been partially transformed into land. Further advance was impossible by reason of the elements, earth, and water.

DIFFICULTIES IN THE ADVANCE: RAPID EVACUATION OF WOUNDED.

Wonder is often expressed that after a large action the advance is not more rapid. The example of little things will help towards an understanding. The morning after, I was making my way through crater and crevass upon some special business, when I saw a boy gathering flints in a sand-bag. We two seemed to be alone in the world. There were others, but they were concealed as they toiled up the holes and hollows. He was finding material to make cement for wheel bases of the guns. A mule climbed out of the earth. He had a pannier with six shells on each side. The advance was laborious as that. Horses must have footing, else they will go downward instead of forward. Roads must be built from the bottom upward, and material for railways must be carried by the strength of men.

Sixteen battalions were engaged on this 1000-yard front, 16 men to a yard. Each one had its piece to do, and when done another battalion passed through and took up the advance. All winter the performance had been rehearsed behind the lines on a terrain marked off with tapes to imitate the battle area as discovered by aerial photographs. To each battalion was allotted a certain number of minutes for its task. All was over by 2 o'clock, and before darkness fell the field was clear. The evacuation from the front was so perfect and rapid that cases began to accumulate at the advanced dressing station; and there they lay, a piteous spectacle, but their presence was the finest tribute ever paid to the Medical Service. A general passed by, and when he saw the wounded lying in ranks on each side of the road, covered with snow, he thought the Medical Service had broken down, until it was explained to him that all casualties were dressed and fed, eased with morphia, and covered with blankets, instead of lying where they fell. Additional convoy was procured, and by midnight all were in their beds. That day's work was over.

THE MEDICAL SERVICE OF A DIVISION.

You have heard much of our unpreparedness for war, but the Medical Service leaped up full-armed when the first call sounded. For long years the Royal Army Medical Corps had worked upon the problem and found a plan. This plan had been adopted in Canada, was well understood, and the two services have operated in a perfect harmony. The best of the profession volunteered, and many of them had some previous training in military affairs. In my own small unit we had in command a surgeon of the first rank; second, an officer who was at once a surgeon and a soldier; third, a dermatologist of the first class, two accomplished physicians, and at least two surgeons who had already had a thorough training. Indeed, I have heard it said that the professional qualification of the men at the front is too high. A man who can succeed in medicine and surgery can succeed at anything.

It is a canon of military law that one may neither praise nor blame his superior officers; and I am neither praising nor blaming when I say that our D.M.S., Surgeon-General Foster, is a master of organisation, proven by two years' service in the field from Ypres to the Somme and back to Souchez; that Colonel Ross, his successor in the corps, has not left the front since the early days of 1915; that our A.D.M.S., Colonel Fotheringham, was on the strength for nearly 30 years, and had long been one of the leading consultants in Canada; and that his successor, Colonel Jacques, who was in immediate command during that day's work, has had 10 years' experience in the permanent force. It was, then, not by accident that the work went well.

It must be hard for you to understand how strictly military is the Medical Service at the front, that is, the service in the division as distinguished from the service on the lines and at the base. Between the two a gulf is fixed; and it is with the division we are especially concerned to-night. In a division there are about 20 regimental medical officers, and three field ambulances with 9 medical officers each, or 27 in all. The personnel is divided into bearer, tent, and transport sections, comprising 250 men, or 750 to the three ambulances. For transport each ambulance has 50 horses, 7 motor and 3 horsed ambulances, with general service, limbered wagons and carts. Each section is self-contained, and marches with bearers, tent orderlies, transport, and equipment. At any moment a section can fall out, march off, and open up with all appliances for life and work in the field. Fuel, food, fodder and water are carried which suffice until rations are drawn. The sections can be as quickly assembled, and the bearers of all ambulances may be pooled for such large operations as took place at Vimy and on the Somme.

For such precise movements a high degree of military training is essential; and in physique the men must be the best, for the work is heavy and the marches arduous. These ambulance bearers and their officers have their advanced headquarters 200 yards from the parapet in the regimental aid-posts, and in action they go over just behind the infantry. They are trained soldiers, the transport carried arms until quite recently; they were practised in musketry, and all were qualified to take their place on parade with the other elements of the division.

The Red Cross no longer exists except as the emblem of an eleemosynary institution which provides an outlet for the love of civilians for their soldiers. The Medical Service has become an integral, and not an ancillary, part of the Army. The Red Cross provides no especial protection because it is so closely identified with the service that neither side can recognise it, although I am bound to say that I have never seen any deliberate violation of the traditional emblem. On the contrary, I think the enemy has withheld his fire from our stations which could be observed as such. He has, of course, destroyed our ambulances by shell fire; he has killed our officers and bearers; he has dropped shells and bombs upon our stations—but that is the chance of war.

A field ambulance, then, is not especially a medical problem. In my own unit, which contains nine medical officers, the Colonel fell at Courcelette, a Major gained the D.S.O., two Captains won the Military Cross, two were mentioned in despatches—all for military virtue as apart from professional knowledge and skill.

PREVENTION AND TREATMENT OF SICKNESS.

But this day's work was merely an incident or an interruption in the regular work of the Medical Service. We have several million of men to keep in health and care for in sickness, and the system by which those ends are gained is much more efficiently organised than it is here in London for the civil population. First come sanitation and prevention of sickness. In all this time I have never detected a foul odour except the fœtid odour of asphyxiating gas or the noisome smell which arises when an old burying-place is disturbed. Except for a few days on the Somme, I have not seen more flies than one would see upon a well-kept farm. Purified water is put into the men's bottles. To drink from an unauthorised source is a crime. Wells are examined even whilst they are yet under fire and the food is scrutinised before every meal. Men are bathed as methodically as they are fed, and by fire and steam the advances of the humble, but friendly, louse are discouraged. One acquires a certain pity for this most dependent and helpless of all creatures—his means of livelihood are so restricted and he is so unbeloved. A battalion of 1000 men can be inoculated in 35 minutes; that is an illustration of the speed and organisation of the Service.

The number and variety of hospitals is almost perplexing and it taxes one at the front to remember where each class of case is to be sent. Mild infections go to one place, more virulent cases to another, and the channels are kept distinct. There is segregation or quarantine, and a mobile laboratory is always available for exact diagnosis.

I am astonished continually at the extraordinary talent that is available. London itself is not more rich. Specialists abound on every hand. A man came to me with an obscure skin disease. I referred it to our Major, who just happened to be a dermatologist. He named the condition "erythema multiforme exudativum iris." The diagnosis was written on a field medical card, and with the man it went forward to England. It came under the eye of one of the most famous of London specialists. He sent back an inquiry through the usual channels because the diagnosis was correct; and he was, I thought, a little irritated, as he supposed no one in the Army but himself was entitled to make so fine a distinction. It turned out that this young Canadian Major had once been a pupil of this London dermatologist.

The Medical Service, above all other services, has done its perfect work. It has yielded an army without sickness. I have never seen a case of typhoid, and the few infectious cases are of the nature of children's diseases—measles, mumps, chicken-pox. For the first time, also, in the history of the world we have an Army which is free from venereal disease. For a time it was part of my business every morning to scrutinise the returns from 30,000 men, and days would pass without a single case, especially when leave was off. We have come to think of London as a place where men contract venereal diseases. That is a saying which I commend to you. There are occasional sporadic cases. To conceal the disease is a crime. The infected man is handed over to the assistant provost-marshal, who ascertains the source and has the source of contagion deported. The disease is regarded as a self-inflicted wound by which a man may secure his return from the front, and some base fellows contract the disease deliberately, just as they shoot off their fingers or toes. In one house were two women. One of them was infected and the other was free. The one who was infected demanded 4 francs for her services; the other had to be content with 2. I can recommend

to you a provost-marshal who will free England from venereal disease in six months. It might be worth the effort.

The Medical Service is no longer the poor relation of the Army. By the miracle it has performed of keeping the Army fit the consideration accorded to the service is unbounded. New problems face it every day, problems that must be solved. Trench feet in the first and second winters were likely to cripple the Army. Last winter the methods of prevention were so sure that a case of trench foot was a curiosity and brought stoppage of leave upon a battalion which produced them. Medical officers may not command; they advise. But he would be a rash commanding officer who would disregard advice repeatedly given.

For a year we were perplexed by trench fever, and I am afraid we showed too little sympathy with the men who were suffering from the malady. The pain in the shins, which is almost intolerable, was too often attributed to myalgia, but, thanks to the service at the base, we now know better. We have learned to discriminate between the varieties of "shell shock," which range from cowardice to mania.

THE OUTLOOK.

By that day's work on Vimy Ridge we convinced ourselves, and proved to the enemy, that we cannot be beaten. After that other, and later, day's work on the Messines Ridge—a ridge I watched for 11 weary months—we can say with surety that we shall win, that the enemy will be defeated, that he will defeat himself in the slow effluxion of time. We are now free to prolong the war until it suits us to bring it to a close. Up to the present we have been fighting for our lives, unable to indulge with confidence in the full hope of a slow, relentless, methodical victory.

In the beginning we were inclined to take the German at his own estimate of himself, to look upon him as a tree walking. Now we have the true measure of him, and we are not in the least afraid. Docile yet courageous, hating other lands yet loving his own, hysterical yet obstinate, he continues to be a formidable foe. Although we have long since matched him in equipment and surpassed him in organisation, we still deceive ourselves about his powers of subsistence, since comfort to him is penury to us. We were close upon his heels in Vimy village, and a detailed examination of his abandoned stores was not encouraging. In one dug-out there were sides of bacon, abundant bread, potatoes, bottled waters, dressings, drugs, articles of new, sound leather, phonographs, and a copy of Kant—by no means a bad equipment for carrying on war. Prisoners who have helped us to clear many a field are capable and diligent, with a certain patient, pathetic helplessness, but a high confidence even yet. Nor do we forget the surety of the enemy's intelligence and his quickness to act upon the results of his experience. Liège, Namur, and Antwerp taught us the futility of the Vauban fortress. Vimy and Messines taught him the futility of massed trenches, and he instantly adopted a new defence. His line is now not a line. It is a fortified country; but to that also we shall find an answer.

The end is not yet, nor is it even in sight. My counsel is that you should close your eyes to the end. Look upon war as a normal condition. Forget it, as all normal things are forgotten. Cease praying for a speedy end—and peace, else you will acquire what the French call the psychopathy of the barbed wire. Peace and the end will come when your unhampered armies shall have performed their task. At one time there was ground for alarm, and excuse for panic. Now there is none. This very night we see the days grow short for the fourth time since we took arms in our hands. Several times we shall see the days grow long and short again before we shall have our will upon our enemy; but we are now free to turn our eyes away from the thing itself and to reflect upon it, to scan the long course by which we have arrived, and so shape our course towards the end—in short, to examine our experience and be governed by it.

In these three years we have seen grow up the most perfect military organisation the world has ever known. This force was created by the genius of this people. It has arisen out of their life, out of their traditions, out of their way of doing things, the tradition, namely, that each man shall go upon his own way with unimpaired liberty, to think, believe, and talk as he likes, to trade as he likes, to work, or refrain from working, with perfect assurance that in time of need the old, dull instinct and dumb sagacity of the race will assert itself, that every man will fall into ordered ranks and proceed upon the appointed way, even unto the end.

THE INSPIRATION OF ENGLISH LITERATURE.

All these years I have heard a cry of self-deprecation and self-pity that we are not as other men—even as the Germans—are. I have seen it urged, for example, that we should retain the classics in our schools, since the Germans spend more time upon classics than we do. The Hun is yet in our hearts. He discovered the association between the teaching of science and material prosperity. There are, on that account, persons now amongst us, interested in education, who never thought of the subject until it was presented to them in this light. If they had their way we should lose the war even by winning it. We have put the matter to the test, and it will be time enough when we have lost to recast any element of our life in a Germanic mould.

We have put all upon the cast of war—our lives, our property, our way of life. We have not yet won. We shall lose, and we shall deserve to lose, if now we are false to the civilisation by which we have attained to these heights, and forsake our old custom—namely, "to defy power which seemed omnipotent, never to change, nor falter, nor repent." We have no cause for repentance. This is not the time to falter or change. You English require no alien teacher. Trust your own. It is written in your books. All else to you will be as a garment put on. Trust your Chaucer, your Shakespeare, your Dickens, your Kipling. They will carry you through. Trust your own poetry, and let German science go. Poetry is the last possible utterance of humanity. Not by wisdom alone do poets write poetry. By some sort of inspiration they say many fine things, and do not themselves understand the meaning of them. It is the Race which speaks.

Illusion is the prerogative of the English. Their strength lies in that; because it goes with eternal youth. When the illusion fades old age has come upon us. It is the inspiration of all our literature, for great writing and all religion is an attempt to weave a veil of beauty to hide the facts of life. All other writing is an attempt to tear this veil aside. This in the work of the cheapjacks of literature and of religion. Religion and literature are great according to the promise which they hold out, like the promise of spring which by some magic persuades the hungry human heart that even the dead will come back to life, the promise to youth of the perfect woman—all dreams of youth which men reverence even after they are awakened. Above all others we have created the illusion of war in virtue of which men go eagerly to their death. If it were not for this quality how should we have survived those dreadful days of 1914?

THE LESSONS OF THE PAST.

To this old race there is nothing new. This is not the first time we have been at war, nor will it be the last. War is always the same in principle, though it may vary in method. Even the battle-fields are the same from the time of Cæsar until now. On the way up from the Somme we followed the very road by which the war-like Henry retreated from Amiens and Peronne and we passed within a little of the field of Agincourt. This area might well be set apart by this new League of Peace as lists which nations must use when they feel that they must fight. At first the situation was new to us. It is over a hundred years since we were at war. All affairs in the interval were merely expeditions, and we still describe our considerable establishment in France not as an army or armies, but as an "Expeditionary Force."

We made one miscalculation—only one. We were well aware that a nation goes to war as a pastime or diversion from the *ennui* of peace. For the first time in our history we found ourselves face to face with an enemy which attacked us as a matter of business.

But for all else you will find precedent. Look in your own old Langland and you will see as in a looking-glass the situation in which we find ourselves to-day. This very people was in trouble with war and want of food. Piers Plowman offered to guide them to the truth, for, he said, Conscience and Mother-wit had showed him her dwelling. But, first, they must help him to finish a piece of ploughing. Remark that the Plowman does not employ women on the land. Those of the common sort are "to sew the sack to keep the wheat from spilling," to "spin wool and flaw," to "weave cloth," and teach their daughters the art. Lovely ladies are to make embroideries "to honour churches." The knights, too, were eager though ignorant. "Teach me,

quoth the Knight, and, by Christ, I will try." The Plowman would have no amateurs—women or men. Let the knight administer justice so as to "keep down the wasters and the wicked men who spoil the world." Then they all fell to work "full eagerly" each man in his own way.

I take it upon myself merely as a Voice to utter one word of warning to this people. It is for England we all are fighting, the England of history, not for a Utopia or any figment of disordered minds. There are disordered minds in our absence working to wrench the old internal polity from its foundations, and no department of life is to remain untouched. There is to be a new electorate, a new drink or no drink at all, a new religion, a new education.

We know what labour is; but we do not know a Labour which confers, and deputes, and strikes, and has Ministers of its own. When a section of the community develops an interest and authority apart from the interest and authority of the community as a whole, there is then in the organism an overgrowth which is at first a foreign body and eventually becomes indistinguishable from a cancer.

In all this spectacle of war the noblest spectacle of all is "the golden metall of our souldiers"; and the means by which we are attaining to victory are the means by which victory has been attained from the days of Ralegh even until now—namely, "the employment of our common English souldier leavied in haste from following the cart or sitting on the shop-stall." To this we have added a new element, the very flower of the flock, the precious offspring of the universities and schools, all our beauty and our youth.

Has this "souldier" from the soil done so badly that his children must be educated from books after the technical, practical, Gradgrind, German method? The soldier will see to it. He himself may have been educated to such a point that he knows the nature of the soil, the place and time for sowing his corn, the public-house which sells an ale most tasty to his palate, the choicest spot in the parish for sunning himself on a Sunday afternoon. In this new hard school of poverty, temperance, and obedience he has educated himself still more finely, and by practising those virtues he has made of himself a "sufficient man."

Only the other day I read a solemn lamentation over the indisposition of the English to speak with foreign tongues. An experience in a ship trading in the Levant was cited. The captain had traded along these coasts for 20 years, and yet could not speak a word of Italian or Greek. His method of unloading his ship was to take a big stick in his hand, make himself red in the face, sweat at every pore, and curse in his own vernacular, whilst an Austrian lying alongside was addressing the natives in their own language. The narrator adds, however, that the stevedores grinned, wondered, and obeyed the English sea captain. It may be that he had the proper way of unloading a ship, and that his education was the best for life in the Mercantile Marine.

THE MESSAGES OF WAR.

The value of war lies in this: it restores simplicity to life, and brings down the top-hamper which peace has superimposed. At the moment you are striving to reform a social life which is passing away. This generation has been dominated by the machine; and all effort has been expended upon machines for making more machines instead of towards the work itself. Science has been crying aloud: "Come and see what I will do for your souls"—and we have seen. I think that in future his giantship will go somewhat crestfallen, and that machines and those who tend them will have less power.

The danger of insidious revolution is a real one. By winning this war we may lose it. Equal in importance to winning the war is making ourselves worthy to have won it. The winning of three wars was the ruin of the German, and we have seen the process of degradation with our own eyes. Up to the present generation there was a German with human ideals, that Germany about which Carlyle gabbled—by which he wrought us much evil—and Matthew Arnold, the first of our own heretics, vaunted continually; but we have seen it become detestable by reason of a carnal and spiritual vulgarity. There is no primitive truth in its inward parts; even when its words are sincere its thought is double. This people, which was once great, took its place at the mill like a blinded giant, turning out meanness and cheapness for any Philistine. It lost all sense of beauty. Music died in the orchestration of Wagner and the heathen shouting from the stage; literature perished in a contemplation of their national hero who sacrificed his soul for the lusts of the flesh—an elderly professor with the powers of Hell at his command, whose ultimate good was science and the violation of women.

Even yet I see no signs of repentance. Evil is yet their good. But I think I do witness a sign that the just and righteous judgments of God are about to fall upon hardened and unrepentant sinners, and that this Caliban which yet, alas! squats athwart the pleasant land shall soon quit the earth and depart to his own place in the cold void of history. His habits are not new. Two hundred years ago we saw the work of the Hun in Scotland. You know him as the Duke of Cumberland. By common consent we still describe him as the "Butcher." But we, for our good, are reviving amongst us certain primitive truths: that a nation cannot exist which is detached from the soil, and that the perpetuation of the Race depends upon the primitive in Woman.

Mistrust, then, your lesser intellectual breeds: your young Byrons who cursed when Waterloo was won, your young Wordsworths who cast up the red caps of Revolution, as many in these days are casting up their caps too soon. Mistrust your "intelligentsia," mere bores and busybodies, who seize the moment to put into effect their vagaries. A nation governed entirely by the paid leaders of men who work with their hands may prove to be no more desirable than a nation governed by men who trust in their sword arm alone. To exchange a military union for a trade union is to exchange thongs for scorpions. Depend upon the safe, solid sense which you have inherited from your fathers. These are no times for experiments. We have been saved in former times, and we shall be saved again if we put our trust in the old, unaltered blood, in the passion, the piety, and the prowess of the line.

You have heard it said that all great wars in the past were religious wars. This, too, is a religious war—against the calculated atheism which would make of religion a speculative department within the bounds of the scientific spirit. This is the spirit against which the mediæval church continually strove by persuasion, remonstrance, and cursing, and finally called to its aid the secular fire and sword. The church with profound instinct discovered the tendency which would inevitably produce a race of logical German ultra-Protestants of which the Fathers prophesied. It may, indeed, be that the German has lost his soul; for races, nations, and men do arrive at a point where they have no soul to save.

I think that this class of intelligentisia has been worse infected, and has done more than any other to spread the Germanic virus. Even in the universities the "German-trained" scholar was the thing, and in those doubtful, early August days their influence was against the instincts of the people. Quite recently I heard one of them say that he considered the German method for disposal of their dead "extremely sensible."

When I came overseas, I called upon one of these "scientists," and he could not restrain his astonishment over the queer garb I wore. He asked me the meaning of it. I did not tell him. He would not understand. In a place so remote that many of you have never heard its name the alarm of war reached us 24 hours after it had sounded. A boy was sitting beside me reading a book. He laid down the book and walked a little way. I picked it up and read:—

> "It is not to be thought of that the flood
> Of British freedom which to the open sea
> Of the world's praise from dark antiquity
> Hath flowed with pomp of waters understood—
> That this most famous stream in bogs and sands
> Should perish, and to evil and to good
> Be lost forever."

The boy came back and said, "I think I will go to the war." "To-night or in the morning?" I asked. "In the morning," he said. He went away in the morning. I saw him next in Plug Street Woods. A little child does sometimes lead safely.

In the absence of your soldiers keep the national emblems bright. Keep the fountain of honour undefiled. The majesty of the King appeals with peculiar intimacy to all who can claim the northern kingdom for their home, or the home which their fathers left to adventure over other seas. By nature we are Royalists, and upon this matter we are not likely to suffer from false illusion. The Crown has become the seal and bond of Empire. We from over-seas are not especially enamoured of your Houses of Parliament or of our

own either; and, if we can believe what we hear, you yourselves have no great pride in them. These Houses would do well to remember that there is always an appeal to the King, and when such an appeal is made by men accustomed to arms it is likely to be irresistible.

What love we have lost for Parliament we have reserved for our King. A soldier's love for his King is a passion in itself as profound in nature as the love of man for woman. It is only measured by the degree to which the soldier himself is kingly. No soldier will ever forget the day when the King rode athwart our closed columns and looked into one's eyes with his lovely Stuart eyes. He is the final human being to whom the humblest soldier may make appeal. This instinct of the soldier of our race, that even in this world in the person of the King lies an abode of justice and mercy, is as ineradicable as the instinct which impels men of every age and race to lift beseeching hands to Our Father which art in Heaven.

Reflections
ON THE
LIMITATIONS OF VACCINE TREATMENT.[1]

BY ROBERT J. ROWLETTE, M.D.DUB., F.R.C.P.IREL.,
SENIOR PHYSICIAN TO JERVIS STREET HOSPITAL, DUBLIN.

IT is my aim this evening to sketch very briefly the place that vaccines should take in therapeutics, and to consider what may fairly be expected of vaccine treatment and what are its limits. I am aware that the observations I have to make are obvious and even commonplace, but I have often heard them overlooked both in public discussion and in private conversation.

THE DIFFICULTY IN ESTIMATING THERAPEUTIC RESULTS.

It is notorious that no judgment in medical practice is more difficult than the estimation of the value of a particular method of treatment. A new method is introduced, it wins a certain amount of favour, it may become the fashion, and unless it is accompanied by some obtrusive disadvantages or dangers, many of us are convinced that the treatment is, if not "the last word," at least "a distinct advance," and we go on with it until a new fashion takes the place of the old. Our reasoning on these matters is never logical, and rarely individual. We are governed by laws—if they be laws—of herd psychology. Our conclusions are instinctive, not conscious.

This is, in part, due to the difficulty of forming a judgment of cause and effect in a highly complex set of phenomena. It is difficult or impossible to arrange a therapeutic experiment in such a way that the conclusion is irresistible. The problem is not so complicated in surgical as in medical treatment, as the conditions more closely approach those of scientific experiment. Nevertheless, surgeons are not free from the influence of fashion—that is to say, from the sway of inaccurate judgment. Gastro-enterostomy, appendicectomy, colectomy, Jackson's membrane, have all had their vogue, and the nuciform sac is not the exclusive specialty of an imaginative surgeon.

In every branch of medicine we meet this difficulty of estimating therapeutic results, but in the case of vaccines the difficulty has been increased by certain more or less accidental circumstances. Vaccine treatment came to us as a gift from the laboratory. It came, therefore, with a certain scientific pedigree which demands for it our consideration, but it is often presented by men trained in laboratory methods, without clinical experience, and without the knowledge necessary for the comparison of therapeutic results. On their side, clinical workers, being unfamiliar with the technique of vaccines, have been content to leave their administration to those who were. It has come about, therefore, that for years, and, indeed, to a certain extent to the present day, vaccine treatment has remained in the hands of men of laboratory training. It is, however, clinical experience, and that only, that can seal its value.

[1] An address delivered before the Section of Medicine, Royal Academy of Medicine in Ireland.

The enthusiasm of the introducers of vaccine treatment—an enthusiasm often untempered by clinical experience—has put forward somewhat extravagant claims. These claims, misunderstood and misrepresented, led the optimistic to expect miracles. But miracles do not happen, and those who were disappointed, on the one hand, and, on the other, those who had their prophesyings of evil accomplished, agreed to declare that they had been hoaxed. The number of successes, however, was sufficient to keep up some belief in the miracles, and between the faithful and the sceptic there seemed to be no common ground. Certain trading firms saw their opportunity, and by making impossible claims for inferior products caused both disappointment and disgust. In short, an abnormal state of mind was produced which has prevented the profession exercising a normal judgment.

We have, however, passed through both elation and depression, and we are, I hope, now in a position to judge coolly of the rightful place of vaccines in treatment.

PREVENTIVE INOCULATION.

First, as regards their place in preventive medicine. The experience of the present war puts beyond all question the value of preventive inoculation against the enteric diseases. Our troops have been inoculated against typhoid, but not at first against paratyphoid. We know how rare has been typhoid, although paratyphoid, hitherto regarded as a rare disease, has been in some areas by no means uncommon. Yet medical officers from most of the fronts have made us familiar with the insanitary conditions under which the men have to live and of the gross contamination to which much of the drinking water is subject. If our troops had to rely merely on sanitary precautions in the ordinary sense and were not protected by inoculation there does not seem to be any reason why they should not suffer from disease as troops suffered in South Africa and in most other campaigns in history.

In our ordinary home-medicine we have also experience of the efficacy of preventive vaccination, particularly in the results of inoculation against recurrent catarrhs of the respiratory organs. The problem is more complicated than in the case of typhoid in that we are dealing with infections by organisms with which we are not so familiar and, moreover, we are dealing not with a single organism, but with several, out of which it is a matter of difficulty to select the main infective agent. We have not, therefore, as good a record of success as in inoculation against enteric, but, nevertheless, successes are sufficiently numerous to justify us in the hope that with a more intimate knowledge of the bacteriology of the respiratory tract, and more particularly with the development of knowledge of a correlation between the different forms of respiratory catarrh and different species of bacteria, we may soon be in a position to judge what class of cases may be satisfactorily treated and what class we cannot expect to influence. It must not be forgotten that the attacks of some diseases, of which the best example is perhaps influenza, do not appear ordinarily to confer immunity, or at any rate an immunity which persists for any length of time. In the case of such diseases we are not likely to produce any persistent effect by preventive inoculation.

VACCINE TREATMENT: ACTION AND LIMITATIONS.

I have dealt with the question of preventive inoculation first for two reasons. In the first place, the claims made for vaccines are admitted. But, in the second, the consideration of the prevention of disease by immunisation helps us to understand what we have a right to expect from vaccines in curative treatment. Active immunisation is the training and marshalling of the protective forces of the body against a particular kind of attack. That is to say, it is an attempt to stimulate a natural process—the process by which the body naturally defends itself against bacterial invasion.

A vaccine is not a new ally in the fight between the parasite and the host, assisting the latter to destroy the former. It is only a stimulus to the body to exert to the full its natural powers of resistance and protection. Of itself it can do nothing. Although, then, one rightly speaks of vaccine treatment as specific, it is specific in quite a different way from the so-called specific action of drugs. We suppose quinine to be specific for malaria, and arsenic or mercury for syphilis, because we believe the drug in each case to exert a

special destructive action on the infecting parasite. But vaccines are only active against bacteria mediately in that they stimulate the production of bodies which possess special destructive powers toward particular organisms. Vaccines are, therefore, in a sense only specific at second-hand.

As the action of vaccines is merely stimulative of certain natural powers of the body, it is clear that if the body is already exhausted, if it is no longer able to produce the substances, the vaccine fails. Moreover, in cases where it does not fail, its success is proportional to the power of the tissues to respond to its call. To expect uniform success from vaccines is therefore as unreasonable as to suppose that the body can never fail in its defence against attack.

It follows that the cases in which we may expect the best results of vaccine treatment are those in which (1) the body has not yet lost its natural power of resisting infection, and (2) in which there has not been great tissue change. If the body has no power of resisting infection the vaccine is quite inert. It is as useless as a trumpet-call in a deserted barrack-square. It is not possible to tell whether such cases really occur, nor how to recognise them if they do. We must, however, be prepared to meet them and not to be disappointed if the inevitable happens.

The second qualification is of more practical interest. When grave tissue changes have taken place we cannot hope by any method of treatment either to restore lost tissue or to cause the absorption of masses of new tissue of a degenerate order. Vaccines can only produce a resistance to an infective process—they have no effect in dealing with the results of that process after the process has ceased. I do not suggest that there are not other agencies in the body at work to restore damaged tissue to the normal, but these agencies are neither helped nor hindered by vaccines. Let me take one example:—

A Fallopian tube becomes infected by, let us say, the gonococcus and suppuration follows. While the infection lasts, its progress may be hampered or prevented by vaccine treatment. But once the gonococcus loses its vitality, vaccines give no help to the tissues in their struggle to return to the normal. Neither will vaccines cure a stricture of the urethra consequent on gonorrhœa. This is so obvious as to appear commonplace. But let us supply the same reasoning to the effects of rheumatic infection, whether on the joints or on the valves of the heart. We may reasonably hope to hamper the progress of rheumatic injury or to arrest it altogether. But if gross tissue changes have occurred, they cannot be repaired by vaccines. It would be as reasonable to suppose that, if the invaders were to-morrow driven from the fields of Flanders, those fields would be restored forthwith to the condition in which they were three years ago. The battle may be over, and the invaders destroyed, but many of the traces of battle are ineradicable, while others will persist for years. Louvain and Ypres will never be again what they were three years ago. Neither will the heart valves that have been eroded and fibrosed in the battle between the infecting cocci and the protective agencies of the body be the same again.

Scope of Vaccine Treatment.

The question is not infrequently asked, What class of diseases should vaccines be employed in? The answer, bearing in mind the limitations I have already suggested, is, Every infective disease due to bacterial origin in which the bacterial cause can be discovered. The acuteness or chronicity of the condition is beside the point, though it may have much to do with the method of administration. A similar remark applies to the question whether the disease is general or local. In every case where a fight is going on between the body and an invading bacterium there is reasonable hope that the defensive forces will be strengthened by the administration of a vaccine. But, as vaccines are specific, a correct bacteriological diagnosis is necessary. In this vaccines are at a distinct disadvantage if contrasted with other methods of treatment. By rest, suitable food, good nursing, and relief of unpleasant symptoms we cure, or rather assist nature to cure, many of our patients. If before treating them an accurate diagnosis were necessary how many successes would we have? But if vaccines are to have any effect at all their use must be preceded by correct diagnosis. We must be sure that we are treating with the infecting organism. Of course, if the infection be mixed, as is so often the case, we must often be content to treat with a group of organisms—i.e., with a mixed vaccine—being assured that at least one element in our vaccine is specific for the infection, and that the others, if not helpful, are at least harmless.

No greater misconception can exist than the notion that vaccine treatment is incompatible with the use of other methods of treatment. On the contrary, one rarely gets the best results from vaccine treatment unless one makes full use of whatever concomitant measures his own experience or the accumulated experience of others may suggest. Few drugs are in any way inimical to the action of vaccines, and those that are, are depressant to the natural resistive powers of the body, and are therefore contra-indicated in the class of diseases in which vaccines are employed. Of these the only drug in common use is alcohol, the employment of which in septic diseases should by now be obsolete except under rare conditions. Vaccine treatment, therefore, goes side by side with treatment by drugs.

In surgical conditions, operative measures, or anything else that surgical knowledge suggests should, of course, be practised when required. The only precaution to be observed is to withhold inoculations in immediate proximity to any manipulative proceeding which may gives rise to auto-inoculation. Otherwise vaccines, of course, act in their normal manner of increasing the protective power of the body.

I said at the beginning that much misjudgment of vaccine treatment by the profession has been due to the treatment being so largely committed to men unaccustomed to clinical work. It cannot, however, remain in the hands of a special class. As an important branch of therapeutics it must become familiar to every practitioner. No student can be considered to have gained a sufficient knowledge of therapeutics who has not become familiar with both the doctrine of immunity and the practice of immunisation. In this way vaccine treatment will come to take its proper place—not as something peculiar and special, but as an essential part of the treatment of infective disorders of bacterial origin.

Dublin.

A VARIETY OF

WAR HEART

WHICH CALLS FOR TREATMENT BY COMPLETE REST.

By ARCHIBALD E. GARROD, C.M.G., M.D. Oxon., F.R.S.,

COLONEL, A.M.S.; CONSULTING PHYSICIAN, BRITISH MEDITERRANEAN FORCES.

Two chief factors are concerned in bringing about the heart troubles of soldiers. One of these, the physical and emotional strain of military life, has attracted much attention since the war began, and the group of symptoms named by Dr. T. Lewis and his fellow-workers the "effort syndrome" has been treated of by many medical writers. The second factor, the temporary weakening of the heart muscle by campaign diseases, has received much less notice.

Among soldiers of the Mediterranean Forces the effort syndrome has been as much in evidence as on the Western front, but we have also seen very many cases in which malaria and some in which other epidemic diseases, such as dysentery and trench fever, have left the myocardium damaged for a time.

It is the aim of this note to call attention to these cases and to emphasise the fact that treatment by graduated exercises, which has proved so useful in the differentiation and cure of the functional cases, is unsuitable and *does actual harm* in the organic cases, so long as the physical signs of damage to the heart muscle persist.

The symptoms described by the patients are shortness of breath on exertion, inability to walk any distance, and, in some cases, præcordial pain. The physical sign is an extension of the cardiac dullness towards the right, often to 1½ or 2 inches beyond the mid-sternal line. Only in extreme cases is there any conspicuous extension towards the left. The dull area has a clearly defined outline, and yields a sense of resistance on percussion. The resistance can also be appreciated by dipping, with the pads of the fingers, along the course of the ribs or intercostal spaces. This method of palpation was taught me, years ago, at the Hospital

for Sick Children, by an American friend and pupil, Dr. T. Wood Clark, and I am convinced that, as a means of marking out the cardiac area, it supplies a valuable control to percussion. It is better to mark out the area by palpation first, and to check the findings by percussion.

I am well aware that some physicians, whose opinions are entitled to all respect, deny the possibility of determining the right border of the cardiac area by percussion, let alone by palpation, but this is wholly at variance with my experience. Many of us working in association here (as previously in England) have examined cases and have checked each other's findings, with open eyes and blindfold. We have agreed in our markings, have watched the drawing-in of the area of dullness under treatment, and its re-expansion after renewed strain or relapses of malaria, and are confident of the correctness of our observations. My colleague, Colonel H. H. Tooth, allows me to quote him as endorsing this statement. Murmurs are not often heard in the cases under discussion, and when present are of the functional kinds, so common in soldiers. The patients are many of them anæmic, but there is no obvious relation between the degree of anæmia and the increase of the cardiac area. Their blood pressure is often above the normal for their ages, as is usual in soldiers who have recently been on active service, and often fluctuates widely with position, emotion, or exercise. The great majority are of the younger military ages.

The signs described are such as my late colleague, Dr. D. B. Lees, taught us to look out for in rheumatic children, in whom the enlargement of the cardiac area, ascribed to myocarditis, often precedes any indication of endocardial lesion.

The X ray shadow of a normal heart extends some way beyond the right border of the sternum, and the right auricle, to which this shadow is mainly due, is covered by the edge of the lung. Extension of the cardiac dullness to the right must indicate a pushing aside of the lung and the bringing of a larger area of the heart's surface into direct contact with the chest wall. My assistant, Major G. Graham, has pointed out that the abnormal dullness is abolished when the patient draws and holds a deep breath. Presumably the dullness results from dilatation of the auricles, especially of the right auricle, and it does not necessarily follow that such dilatation will cause a conspicuous extension of the cardiac shadow. Major Graham is making a series of accurate measurements of the shadows of such hearts and of normal controls. His results, which are as yet incomplete, will be recorded by him in due course.

We have had opportunities of watching the effects of various treatments in these cases of post-malarial dilatation, and in one of our military hospitals wards have been set apart for them under the care of Dr. Prudence Gaffikin. It is to be hoped that she will publish an account of her results later on, and it is only necessary to give a few general conclusions in this note.

Our experience has convinced us that the fitting treatment for such patients is complete rest until the cardiac dullness has returned to its normal limits and for at least a week afterwards. The hearts of many patients which have not responded to modified rest have come in after complete rest has been imposed. The patient is not allowed to rise from his bed for any purpose, nor even to sit up in bed for his meals, nor is he permitted to smoke. We have seen patients who have been treated by exercises *ab initio*, and others who have been allowed up after a short period of rest, although their hearts were still dilated. Neither plan has anything to recommend it, and the results have been wholly unsatisfactory. When the dilatation is recent the cardiac area may return to its normal limits within as short a period as a week. In cases of longer standing, in which rest has not been imposed at the outset, longer periods, up to six or eight weeks, have been required. In no case has the heart failed to come in sooner or later.

In Dr. Gaffikin's wards the patients have begun gentle resistance exercises in bed 10 days after the cardiac dullness has come in. Then follow graduated exercises in the erect posture, and, if all goes well, they are sent to a convalescent camp, where the exercises are continued, under careful medical supervision, in an organised heart clinic.

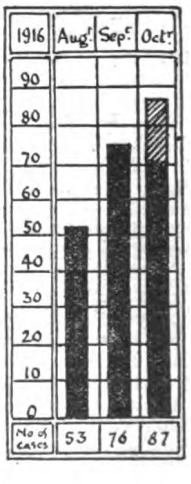
As a rule, under such treatment, the heart does not re-dilate. If the area of dullness should again spread to the right a further period of rest is imposed. In some cases a relapse of malaria has caused a return of the signs, even during the period of complete rest. A few patients show a great liability to repeated re-dilatations under very slight provocations—a condition for which the apt nickname of "concertina heart" has been coined. Drugs play a comparatively small part in the treatment. Some of us advocate digitalis, and others nux vomica, but I am not convinced of the efficacy of either. Major Graham believes that digitalis lessens the chance of re-dilatation.

To sum up, the "soldier's heart" is not a clinical entity, but includes a variety of morbid states. Even amongst those patients who exhibit what is called the "effort syndrome," some respond well to exercises and others do not, and it is one of the chief claims of the exercises that by their means we are able to sort out the fit from the unfit. Again, as I have tried to show, we meet, in the course of our military work, with cardiac troubles in the treatment of which the most important factor is rest.

Malta.

AN ANALYSIS OF CASES OF TETANUS TREATED IN HOME MILITARY HOSPITALS

DURING AUGUST, SEPTEMBER, AND PART OF OCTOBER, 1916.



BY SIR DAVID BRUCE, C.B., F.R.S., F.R.C.P.,
SURGEON-GENERAL, ARMY MEDICAL SERVICE.

TWO analyses of cases of tetanus treated in home hospitals have been published in THE LANCET—one on Oct. 23rd, 1915, the other on Dec. 2nd, 1916. This paper continues the subject, and gives an analysis of the cases which occurred in August, September, and part of October, 1916. During this time reports on 200 cases have been received; of these, 127 recovered and 73 died—a mortality of 36 5 per cent.

In the first analysis there were 231 cases, with a mortality of 57·7 per cent.; and in the second 195 cases, with a mortality of 49·2 per cent. This shows a regular and satisfactory fall in the rate of mortality, which it is hoped will continue until the 20 per cent. aimed at is attained. This fall is probably due to the introduction of the primary prophylactic injection of antitoxin, and also to the earlier diagnosis and earlier specific treatment of the disease. If the fall continues it will depend on the introduction of multiple prophylactic doses, the vigilance of nursing sisters in detecting early symptoms, and the prompt and thorough treatment by medical officers by means of antitoxin.

It had been intended to give an analysis of cases of tetanus treated in home hospitals at the end of each year of the war. Now it is thought better to give one at more frequent intervals. This is due to the great interest taken in the subject by medical officers in charge of wounded at home. It ought to conduce to the keeping up of this interest if the results of new recommendations made by the Tetanus Committee be reported on at more frequent intervals than one year. In fact, the intention at present is that in future each series of 100 cases as they are completed will be shortly reported on.

DIAGRAM 1.

During the same time two analyses have been published by Colonel Sir William Leishman on the cases of tetanus occurring among the British troops in France. In the first, 179 cases were dealt with, with a case mortality of 78·2 per cent. In the second, in collaboration with Major A. B. Smallman, 160 cases were analysed and gave a case mortality of 72·7 per cent. The cases dealt with in France are naturally more acute and severe than the cases which arise in England.

THE DISTRIBUTION OF CASES OF TETANUS DURING AUGUST, SEPTEMBER, AND OCTOBER, 1916.

Diagram 1 represents the number of cases which occurred in each month. Sixteen of the cases which occurred at the end of October do not come into this analysis. The diagram

merely gives the number of cases which were treated in home hospitals during each month and has no relation to the number of wounded.

RELATION OF THE NUMBER OF DAYS WHICH ELAPSED BETWEEN THE DATE OF WOUND AND THE ONSET OF SYMPTOMS AND THE RATE OF MORTALITY.

Diagram 2 shows that in the cases dealt with if the symptoms of tetanus appeared within ten days of receiving the wound the mortality was 42 3 per cent. ; if between the eleventh and twenty-fifth day, 36 9 per cent.; the remaining 67 cases, with an incubation period of from 26 to 365 days, 25·3 per cent. This shows an all-round improvement.

THE INCUBATION PERIOD, OR NUMBER OF DAYS WHICH ELAPSE BEWEEN THE DATE OF WOUND AND THE ONSET OF TETANUS SYMPTOMS.

Curve A shows the number of cases which occurred on each day after the date of the wound. The shortest period of incubation was three days and the longest 365. More cases occurred on the ninth, eleventh, and fourteenth days than on any other. There were only 26 cases with a short incubation period—that is, up to 10 days, and 78 cases with an incubation period of more than 22 days. This is very much the same as in the preceding year—27 and 62—which is to be expected since the regulations concerning prophylactic injections were the same in both years. It is the prophylactic injection which governs the incubation period.

It will be interesting to see what effect a second, third, or more prophylactic injections will have on this incubation period. This new recommendation was made by the Tetanus Committee at the beginning of November, 1916. It is sincerely to be hoped that medical officers in charge of wounded will give this new recommendation a fair trial.

THE POSITION OF THE WOUNDS IN REFERENCE TO THE MORTALITY.

It was noted by Sir William Leishman and Major Smallman that a fatal issue is more common when the body, as distinguished from the limbs, has been wounded. Table I. gives the position of the wounds in the 200 cases under consideration. One case had no perceptible wound.

TABLE I.

—	Body.	Limbs.
Fatal, 72 cases	23 (31·9 °/₀)	49 (68·1 °/₀)
Recovered, 127 cases	48 (37·8 °/₀)	79 (62·2 °/₀)

Note.—When wounds occurred both on the body and the limbs the case is counted only under the heading "Body."

From the above table it would appear that wounds involving the limbs are more dangerous than those involving the trunk.

THE EFFECT OF FRACTURES ON THE RATE OF MORTALITY IN CASES OF TETANUS.

Among the 200 cases under consideration there were 73 fractures—36 per cent. of the whole. Of these, 51 recovered and 22 died ; mortality, 30·1 per cent.

Among the 200 cases there were 127 cases without fracture. 77 recovered, 50 died ; mortality, 39·3 per cent.

TETANUS OCCURRING AFTER OPERATIVE INTERFERENCE WITH THE WOUND.

Table II. gives the cases, 17 in all, in which tetanus is reported to have followed on an operation. There were 14 recoveries and 3 deaths, a mortality of 17·6 per cent. In not one of these cases was a prophylactic dose of antitoxin reported to have been given at the time of the operation—in spite of the recommendation of the Tetanus Committee in their memorandum of August, 1916.

CURVE A.

ON OPERATIVE INTERFERENCE AFTER TETANUS SYMPTOMS HAVE APPEARED.

Table III. gives the cases, 15 in all, in which an operation was carried out on the wound after the appearance of symptoms of tetanus. There were 11 recoveries and 4 deaths, a mortality of 26·6 per cent. Last year the mortality in such cases was 47·6 per cent. From this year's figures there would appear to be no marked danger in operating after the appearance of tetanic symptoms. Until more evidence has accumulated the advice still holds of waiting until the tetanus has been got under control, and the blood and tissues flooded with antitoxin before undertaking any drastic interference with the wound.

TREATMENT OF TETANUS BY ANTITETANIC SERUM.

A. Prophylactic or Preventive Treatment.

Among the 200 cases, 102 are noted as having received a prophylactic injection of antitoxin in France immediately after being wounded. Only 3 cases are reported to have received prophylactic injections in home hospitals.

Of these 102, 74 recovered and 28 died, giving a mortality of 27·4 per cent. Of the remaining cases, there is no record of prophylactic treatment in 87, although in all probability most of them received it. Of these 87, 48 recovered and 39 died, a mortality of 44·8 per cent. The remaining 11 cases are stated to have had no prophylactic injection of any kind. Of these, 5 recovered and 6 died, a mortality of 54·5 per cent.

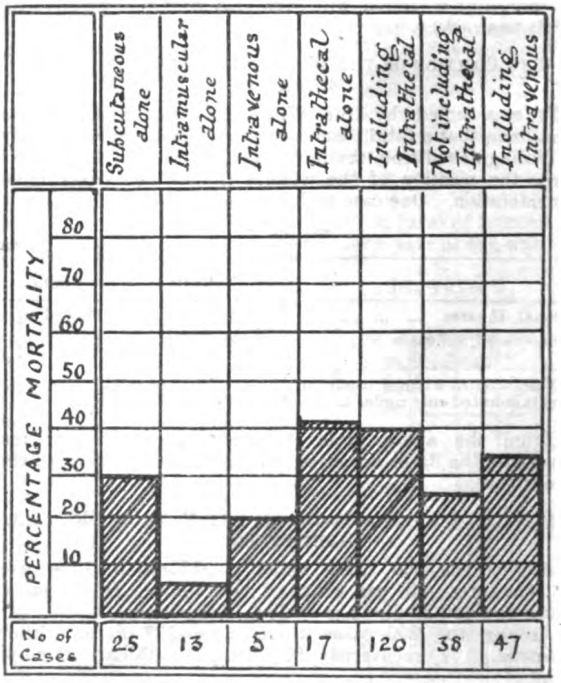
In regard to the question as to what influence time has in these primary prophylactic injections, the following table gives all the information available:—

TABLE IV.

—	Recovered.	Died.	Per cent.
72 cases inoculated on day of wound	50	22	30·5
18 ,, ,, one day after wound	15	3	16·6
6 ,, ,, two days after wound	6	0	—
1 case ,, three ,, ,,	0	1	—
2 cases ,, four ,, ,,	1	1	—
1 case ,, five ,, ,,	1	0	—
1 ,, ,, six ,, ,,	1	0	—
1 ,, ,, seven ,, ,,	0	1	—

Of the 72 cases inoculated on day of wound the average incubation period was 29·5 days. Of the 11 cases which received no prophylactic inoculation the average incubation was 15 7 days.

B. Therapeutic or Curative Treatment.



Out of the total of 200 cases the number treated with antitetanic serum after the onset of symptoms was 198 (99 per cent.). Two cases did not receive therapeutic treatment with antitetanic serum in England; both died. There is no record that either of these men received a prophylactic injection in France. One of them, Private W. H., showed symptoms of tetanus at 1 P.M. on Sept. 17th, 1916, and died at 8.40 A.M. on Sept. 19th. The other, Private L. K., showed symptoms on Sept. 25th, 1916, and died four days later. No reason is given in either case why specific treatment was not used. Of the 198 cases which received serum treatment 127 recovered and 71 died. Mortality, 35·8 per cent.

ON THE INFLUENCE OF ROUTE IN THE INJECTION OF ANTITETANIC SERUM.

Of the 198 cases—	Per cent.
25 were treated by subcutaneous injections alone: recovered, 8 died. Mortality	32·0
13 were treated by intramuscular injections alone: 5 recovered, 1 died. Mortality	7·7
were treated by intravenous injections alone: 4 recovered, 1 died. Mortality	20·0
17 were treated by intrathecal injections alone: 10 recovered, 7 died. Mortality	41·2
There were 120 cases which included intrathecal injections: recovered, 48 died. Mortality	72 40·0
There were 38 cases which did not receive intrathecal injections: 28 recovered, 10 died. Mortality	26·3
There were 47 cases which included intravenous injection: recovered, 16 died. Mortality	31 34·0

It would appear from Diagram 3, which represents this graphically, that no advantage in favour of intrathecal injections emerges from these figures, as seemed to be the case in 1915.

DIAGRAM 3.

IS THERE ANY OTHER EVIDENCE TO BE FOUND IN THESE REPORTS THAT THE INTRATHECAL ROUTE HAS ANY ADVANTAGE OVER THE OTHER METHODS OF INJECTION?

Treatment Beginning on Day of Onset of the Disease.

	Per cent.
During the period August-October, 1916, 96 cases were treated with antitetanic serum on the day the symptoms declared themselves. 54 recovered, 42 died. Mortality	43·7
Out of the 96 cases the following received antitoxin, but not intrathecally, on the day of the disease: 43 cases; 26 recovered. 17 died. Mortality	39·5

Out of the 96 cases the following received antitoxin intrathecally on the day of onset of the disease: 53 cases; 28 recovered, 25 died. Mortality ... ... 47·1

Treatment Beginning on the Day following the Onset of Disease.

During this period 38 cases were treated with antitetanic serum beginning one day after the symptoms had declared themselves. 27 recovered, 11 died. Mortality ... ... 28·9

Out of the 38 cases the following received antitoxin, but not intrathecally, one day after the onset of the disease: 23 cases; 17 recovered, 6 died. Mortality... ... ... 26·0

Out of the 38 cases the following received antitoxin intrathecally one day after the onset of the disease: 15 cases; 10 recovered, 5 died. Mortality ... ... 33·3

Treatment Beginning Two Days after the Onset of the Disease.

During this period 27 cases were treated with antitetanic serum beginning two days after the symptoms had declared themselves; 18 recovered, 9 died. Mortality... ... ... 33·3

Out of the 27 cases the following received antitoxin, but not intrathecally, two days after the onset of the disease: 10 cases; 7 recovered, 3 died. Mortality ... ... 30·0

Out of the 27 cases the following received antitoxin intrathecally two days after the onset of the disease: 17 cases; 11 recovered, 6 died. Mortality... ... ... 35·3

Treatment Beginning Three to Twelve Days after the Onset of the Disease.

During the same period 36 cases were treated with antitetanic serum beginning three to twelve days after the symptoms had declared themselves. 25 recovered, 11 died. Mortality 30·5

Out of the 36 cases the following received antitoxin, but not intrathecally, three to twelve days after the onset of the disease: 10 cases; 6 recovered, 4 died. Mortality 40 0

Out of the 36 cases the following received antitoxin intrathecally three to twelve days after the onset of the disease: 26 cases; 19 recovered, 7 died. Mortality ... ... 26·9

Last year (1915–16) the difference was in favour of the intrathecal route. Now the opposite is true. From these figures it would appear that it is better to defer treatment until the symptoms have been manifest for one or more days. *Quod est absurdum.*

THE INFLUENCE OF DOSAGE ON THE CURATIVE ACTION OF ANTITETANIC SERUM.

From these figures relating to dosage no useful deduction can be made. The only excuse for including them is to enable a comparison to be made, with the amount of serum given in the period August, September, and October, 1916, with that given in 1914–15 and 1915–16.

Remarks on the Therapeutic Value of Tetanus Antitoxin.

This section on the prophylactic and therapeutic action of antitoxin may be concluded with the following criticism. To begin with it is quite evident that no advance in our knowledge of the curative value of tetanus antitoxin can be made from these new figures.

In the two previous analyses it was stated "the main conclusion to be drawn from a study of these cases of tetanus treated therapeutically by antitetanic serum is that it seems highly probable that the serum has little or no effect on the course of the disease." This, of course, must be understood to be merely an opinion formed from the study of these particular figures. It is not the expression of an opinion as to the usefulness or not of antitetanic serum as a therapeutic agent. It merely means that no evidence can be gained from these reports in favour of the curative power of this antitoxin. This is not to be wondered at. The number of cases analysed is small. There are only two controls. The greatest variety in mode of treatment exists. The men are suffering from wounds, septic poisoning, and other diseases in addition to tetanus. The cause of death is credited to tetanus, but in many cases wrongly so. For example, among the 73 deaths in the 200 cases under consideration, 14 at least were primarily due to gas gangrene, septicæmia, heart failure, or pneumonia. Under these circumstances it is not surprising that no conclusive evidence can be gained. The difficulty of arriving at truth in human therapeutics is notorious. It would certainly be very satisfactory, and ample reward for work expended, if the real value of antitetanic serum in the treatment of tetanus could be definitely laid down.

Millions of cubic centimetres of antitetanic serum have been used since the war began. If it could be proved to be of no use it would mean a great lessening of pain and inconvenience to the men suffering from tetanus, and economy to the State.

If it were possible and legitimate to stop all treatment of tetanus in the army by antitetanic serum for six months or a year some valuable information might doubtless be obtained. But this is not practicable since the consensus of opinion of medical officers in this country is decidedly in favour of this specific treatment. The only thing to do, then, is to redouble the efforts to make the therapeutic application of the serum as thorough as possible. This can best be done, according to the Tetanus Committee, by the recognition of early symptoms and the thorough application of the antitoxin without any loss of time by the intrathecal route.

It must be clearly understood that these remarks only refer to the therapeutic or curative use of antitoxin. The enormous value of antitetanic serum as a prophylactic is firmly established beyond any shadow of doubt. It is to be sincerely hoped that there will be no slackening in its use as a prophylactic, and that medical officers in charge of wounded in home hospitals will give the recommendations of the Tetanus Committee in regard to the repetition of these prophylactic doses a thorough trial.

OTHER THERAPEUTIC REMEDIES.

1. *Carbolic acid injections.*—During August, September, and October, 1916, there were only 2 cases treated with this drug, 1 recovered, 1 died. Case 410 is reported to have had ℥10 of a 2 per cent. solution, but how often or how long is not stated. Recovered. Case 444, 2 c.c. of a 4 per cent. solution every two hours for three days. Died.

2. *Magnesium sulphate.*—Only one case was treated. Case 486. Intrathecal injections of ℥40 of 25 per cent. solution daily under nitrous oxide anæsthesia. Died.

CONCLUSIONS.

1. In the 200 cases of tetanus under review the mortality was 36·5 per cent.

2. The greatest number of cases occurred between the ninth and the fourteenth days.

3. Only 3 cases are reported to have received secondary prophylactic injections of antitetanic serum in home hospitals.

4. In regard to the therapeutic effect of the serum the evidence as collected from the August, September, and October, 1916, reports is not conclusive.

5. The summary given in the last analysis in regard to treatment may be repeated.

(*a*) Place in a quiet, darkened room under the care of a sympathetic and capable nurse. "Rest, sleep, and food" are looked upon as the first essentials of treatment.

(*b*) If thorough surgical treatment is carried out on wounds from the beginning so as not to allow the presence of necrotic tissues or foreign bodies, the number of cases of tetanus should sensibly diminish, if not altogether disappear. But if a case does occur then the wound should not be actively interfered with until the tetanic symptoms have subsided.

(*c*) The intrathecal injection of large doses of antitoxin, of high potency if available, should be begun at once and supplemented by intramuscular and subcutaneous injections.

(*d*) In addition, if necessary, the patient should receive sedatives, of which morphia in ¼-grain doses and administered every four hours is perhaps the most suitable. Chloral, chloretone, and other sedatives may also be given by the mouth or rectum.

THE DETECTION OF *ENTAMŒBA HISTOLYTICA* AND ITS CYSTS:

NOTES ON THE TECHNIQUE FOR CONDUCTING EXAMINATIONS OF HUMAN FÆCES.

BY A. C. INMAN, M.A., M.B., B.CH. OXON.,

SUPERINTENDENT OF LABORATORIES, BROMPTON HOSPITAL, LONDON; TEMPORARY HONORARY CAPTAIN, ROYAL ARMY MEDICAL CORPS.

(A Report to the Medical Research Committee from the Laboratory, Mont Dore Military Hospital, Bournemouth.)

IT cannot be denied that attention to detail is the secret of success in laboratory technique. Of no examination is this more true than of the examination of fæces for the detection of *Entamœba histolytica* and its cysts.

Many laboratory workers, bacteriologists and biologists, have of late had to conduct such examinations, though previously they may have had little or even no experience of searching for cysts in fæces. The remarks which follow are not made with the object of instructing such workers how to recognise the *Entamœba histolytica* and its cysts, or in the differential diagnosis between this amœba and other protozoa and yeasts. Such instructions should come, and are urgently required, from expert protozoologists. Rather do they aim at drawing the attention of inexperienced workers to certain details in technique which, in my opinion, will go far towards facilitating their work, and the neglect of which will not only render their work more difficult, but so difficult that even an expert working under similar conditions would be unable to express a confident opinion.

The Microscope: Illumination and Magnification.

1. *The lighting of the microscope.*—The examinations may be made by sunlight or by artificial light. It may be said, however, that one or other of these sources of light should be selected and adhered to; for it is advisable to make all examinations under as nearly similar conditions as possible. For this reason it is best to use artificial light under all circumstances. When available electricity should be preferred to incandescent gas, and the latter to oil. A film should never be examined until the lighting system is satisfactory. Even an expert cannot express an opinion on a cyst if the field of a microscope is faultily illuminated. The source of light should be so arranged that light only enters the eye through the microscope. With this object in view a piece of black paper may be spread under the microscope and the source of light may with advantage be enclosed in a light-tight cardboard or metal shade with a round hole two inches in diameter for the exit of the beam of light on to the mirror of the microscope. My fellow-worker, Mr. D. G. Lillie, places a Crookes's glass over the hole and finds that it softens the light and saves the eye from light fatigue, even after many hours of microscope work.

When electricity is available any powerful electric lamp will do so long as the glass is "frosted." A very serviceable light is the Royal Ediswan Downlite of 50 candle-power, fitted with small opal shades to throw the light well forward. Another lamp to which attention may be drawn is the American Lyhne reading-lamp. It is the most useful laboratory lamp I know of. Not only does it make a very good microscope lamp, but it is eminently suitable for illuminating the laboratory bench when daylight fades, and it forms an ideal light for "reading" agglutination tubes, &c. I obtained mine without difficulty through the General Electric Company, London.

2. *The microscope.*—Any of the good makes of microscopes such as are commonly in use in bacteriological and biological laboratories will serve. There are, however, in addition to good lenses two essentials. Firstly, an Abbe condenser is indispensable for obtaining satisfactory definition when the light is shut off by closing the diaphragm. The latter must be closed sufficiently to render every particle in the preparation clearly visible. Secondly, a mechanical stage is necessary, for the whole preparation must be examined systematically from beginning to end. With this precaution small infections are less likely to be missed, whilst they are sure to be overlooked if the preparation is examined at random.

3. *The magnification.*—Three magnifications—that is, three combinations of objective and ocular lenses—are advisable.

(*a*) The search for amœbæ or cysts should be made in the first instance with a low power. For the little experienced I consider the combination of a ⅔ inch objective with a ×12 compensated ocular, giving a magnification ×192, to be the best. In this way a large field is obtained—an advantage when working slowly—and the cysts are sufficiently magnified to make their recognition a certainty.

(*b*) When an amœba or a cyst is detected a ⅔ inch objective and ×6 ocular should be used. With this magnification (×390) a decision as to the nature of the amœba or cyst can be made in most cases. With a little practice the ×12 compensated eye-piece can be used advantageously with the ⅔ inch objective. A high magnification is thus obtained; the lighting can be adjusted by means of the diaphragm.

(*c*) In doubtful cases, when scrutiny of the nucleus can alone decide on the nature of a cyst, an oil-immersion 1/12 inch objective and a ×6 ocular (magnification ×750) should be employed.

A micrometer scale is essential for the accurate measurement of the size of cells or cysts.

The Preparation of Fæces.

The preparation consists of a suspension of fæcal matter in a conveniently sized drop of liquid on a slide covered with a cover-slip. The suspension should be made with care so as to avoid the retention of all coarse particles. This and the regulation of the thickness of the preparation are facilitated by the use of a dark background. The suspension should be of such thickness that, when covered with a cover-slip, no difficulty is experienced in focussing each individual particle with a magnification of × 390. When investigating a case of dysentery with active symptoms—that is, when blood and mucus are being passed—it is advisable to select carefully small pieces of mucus for examination. Further, such specimens should be examined first in any given batch of fæces, for the diagnosis is facilitated if the movements of the free amœbæ can be studied. As a rule such movements persist when the amœbæ are kept at room temperature, even during the winter months, for at least three to four hours. After this interval they gradually become less and less evident. In the investigation of carriers the cysts are distributed more or less evenly through the fæces, and the portion for examination may be selected at random.

The following fluids may be used for the preparation of the suspension of fæces.

(*a*) Examination in physiological salt solution. This is the accepted fluid medium for the examination for *Entamœba histolytica* and its cysts, and everyone should familiarise himself with the appearance of the various amœbæ and cysts in this solution.

(*b*) Examination in a coloured preparation. (Author's method.) This is an attempt to obtain a coloured preparation in which distinctive colouration is given to those elements demanding special scrutiny, whilst food débris, &c., are coloured with a contrast stain. At the same time, the amœbæ and their cysts retain their characteristic appearance as seen in salt solution. So far it has not been found possible to stain cysts satisfactorily in wet preparations, although, as will be seen later, iodine brings certain features of the cysts into prominence. The method here described depends on the fact that colour can be imparted to the highly refractile cysts by passing the illuminating rays of light through a coloured fluid. The food débris, &c., are actually stained with a contrast stain.

The beam of light from the microscope lamp is passed through a flask of 500 c.c. capacity filled with distilled water to which is added one drop (0·05 c.c.) of a 1 per cent. aqueous solution of methylene blue. The food débris, bacteria, &c., are stained by making the suspension of fæces in a drop of Czaplewski's fuchsin.

Fuchsin 1 gm. carefully dissolved in 5 c.c. of liquid carbolic acid. To this are added 50 c.c. glycerine and 100 c.c. distilled water. For use, take 1 part of the stain to 12 parts distilled water.

On examining such a preparation magnified 192 times the cysts are readily seen as circular highly refractile bluish-white bodies lying among the red-stain débris. Under the ⅔ inch objective the *Entamœba histolytica* cysts appear pale blue and, when present, the chromatoid bodies stand out as bright Cambridge-blue bands. The blue cysts are in marked contrast to the red particles of food débris, &c. A further advantage of the method consists in the fact that degenerate cysts become coloured by the stain, due, no doubt, to their being less resistant to the penetration of the stain. It is not claimed that the method facilitates the differential diagnosis between the pathogenic and non-pathogenic cysts, for such depends on many factors not connected with colour. The *Entamœba coli* cysts, however, assume a greyish tint and are very rarely so blue as those of *Entamœba histolytica*. Unquestionably the finding of cysts is rendered more easy in a coloured preparation, and it is for this fact and for the reason that it has been favourably received by my fellow-workers, who are eminently qualified to judge, that I venture to give publicity to the method.

(*c*) Examination in iodine-glycerine solution. (Author's modification.) The suspension is made in a drop of the following solution: Iodine 1 gm., pot. iod. 2 gm., aq. dest. 200 c.c. Add glycerine in the proportion of 1 drop to every 10 c.c. of the solution. Examination in iodine should only be used as a confirmatory test. The glycerine is added to overcome the difficulty that the iodine solution alone

agglutinates the fæces and renders the finding of cysts more difficult, and the number of cysts in any given sample of fæces appears to be actually reduced. By the addition of the glycerine this disadvantage is largely overcome. The advantage of this method as a confirmatory test is two-fold. Firstly, the nuclei of the cysts are rendered more plainly visible and the outline of the vacuoles is defined. Secondly, certain bodies which otherwise might be confused with pathogenic cysts are clearly differentiated by the stain. Yeasts, for instance, are untouched by the solution, whilst the so-called iodine bodies are stained in so characteristic a manner that they are easily recognised.

In my opinion the examination of stools for pathogenic cysts in all its phases is work for specially trained experts, and can hardly be mastered without a period of practical study under tuition. The experience of the past six months, however, has clearly demonstrated that cases of amœbic carriers are being missed because many of the laboratory workers, engaged in investigating such cases, are unable to recognise the cysts even in their most typical form. It is with the hope that it may prove useful to these workers that this article has been written.

If doubtful cysts are found in the salt solution or coloured preparation another sample of the fæces should be examined in iodine as a routine measure. Many mistakes will thus be avoided. Finally, all who undertake this very important work will do well to bear in mind this golden rule. Never express an opinion on a cyst unless you are satisfied that you have diagnosed it correctly. There will be other cysts about which you will be certain in other parts of the same preparation or in other parts of the same sample of fæces or in other samples of fæces from the same patient. It is worth while waiting for an accurate diagnosis. A hurried, faulty diagnosis can only mislead and may lead to disaster.

THE TREATMENT OF "TRENCH RHEUMATISM" AND ALLIED CONDITIONS BY COLLOIDAL SULPHUR.

BY JOHN D. COMRIE, M.A., B.Sc., M.D., F.R.C.P. EDIN.,
MAJOR, R.A.M.C. (T.); OFFICER IN CHARGE MEDICAL WARDS, SECOND SCOTTISH GENERAL HOSPITAL; LECTURER ON HISTORY OF MEDICINE AND ON CLINICAL MEDICINE, UNIVERSITY OF EDINBURGH.

As a result of prolonged exposure to adverse weather conditions, and especially the extremely unfavourable state of cold and dampness which prevails during the winter months in the trenches, many men suffer from a painful and disabling condition of the muscles. This affects especially the parts which are chiefly exposed to damp—viz., the back and legs, and for want of a better name is popularly designated "trench rheumatism." As a rule the pathological process in these cases appears to be a myositis, which, if aggravated and prolonged, results in a fibrositis with permanent stiffness and deformity. Occasionally the condition is one of arthritis, especially of the knees and ankles; or both conditions are combined. A similar condition occurs among the men, usually of an elderly type, engaged on guard duties in exposed localities at home, but in these men the condition, having as a rule been recurrent for a considerable time, is apt to be more intractable.

Salicylates have had in my experience little effect in relieving the pain and stiffness, which are often considerable, and an attempt was made to introduce into the system sulphur in an easily assimilable form. The remedial action of many well-known anti-rheumatic waters depends upon the presence of this substance, its benefit in painful muscular conditions having long been widely known. Thus, Pliny recommends its application in ointment for lumbago,[1] and also extols the benefit of hot sulphur baths.[2] Paracelsus at the Renaissance appears to have rediscovered its merits, and eulogises it in high terms as "a preservative in all fevers." Since his time sulphur has maintained its high place in popular estimation as a cure for rheumatism, though the only method of introducing it into the body has been to administer the flowers of sulphur by the mouth. One of the most celebrated preparations for this purpose was the "Chelsea Pensioner," a name which indicates the prevalence of myalgia among the discharged soldiers of bygone wars.

Colloidal Sulphur: Mode of Preparation and Dosage.

I was induced by the success which had attended the treatment of acute articular rheumatism by a form of colloidal sulphur in the hands of French observers[3] to try the intramuscular injection of colloidal sulphur in the severer cases of trench rheumatism which came into the wards under my charge. This preparation of colloidal sulphur has the double advantage that it is introduced into the affected muscles in a nascent state and in a form of extremely minute subdivision which offers a large surface for the action of the body fluids. The fineness of the particles may be judged from the fact that whereas the grains of the almost impalpable precipitated sulphur (milk of sulphur) have a diameter of 0·005 mm. or more, the granules of the colloidal sulphur vary from 0·0001 mm. or smaller up to 0·001 at most. The surface presented for absorption by the colloidal sulphur is therefore about 50 times that offered by an equal weight of the precipitated sulphur. The preparation used was made up for me by Mr. George Lunan, Queensferry-street, Edinburgh, who has kindly supplied the following note as to its production:—

"The process used in the manufacture of colloidal sulphur, 1 in 1000, is as follows: Hydrochloric acid (10 per cent. HCl), 22 mils.; sodium sulphide (Na_2S, 9 H_2O), 5 gm.: sodium sulphite (Na_2SO_3, 7 H_2O), 2·6 gm.; white of two eggs; sterilised water to 1 litre. Dissolve the sodium sulphide and sulphite each separately in 250 mils. of the water, mix together; add the white of egg and thoroughly mix. To this solution add the hydrochloric acid, diluted with 250 mils. of the water. The solution is then to be thoroughly mixed, warmed slightly, and sufficient sterile water added to make the volume 1 litre. The solution, after being carefully dialysed to remove crystalloids, is then ready for use. Theoretically, the product should contain 1 in 1000 of colloidal sulphur. The chemical action is explained as follows:—

$$2\,Na_2S + 4\,HCl = 2\,H_2S + 4\,NaCl, \text{ and}$$
$$Na_2SO_3 + 2\,H_2S + 2\,HCl = 2\,NaCl + 3\,S + 3\,H_2O.$$

Thus the sodium sulphite is reduced by the hydrogen sulphide produced from the sodium sulphide and hydrochloric acid. The presence of the albumin appears to prevent the aggregation of the sulphur into masses. In use the dose of 1 mil. is rendered isotonic by the addition of 2 decimils of 5·5 per cent. saline solution mixed immediately before injecting."

The dose with which I have been in the habit of commencing is 1 mil. (i.e., about 17 minims of the colloidal sulphur solution made up to 20 minims with the saline solution) injected into the painful area of muscle. If no reaction results, the dose may subsequently be doubled, the point of injection being slightly varied each time. In a course of 10 injections the affected muscle receives into its substance approximately 1/50 gm., or 1/3 gr., of nascent sulphur which is gradually absorbed.

Results of Treatment.

The following two tables show the effects of treatment in 60 cases. Severe cases only or cases of prolonged duration were chosen for these initial trials, but a large number of other severe and also slighter cases among soldiers and civilians have since been treated with equally satisfactory results.

The 60 cases here recorded include 24 expeditionary and 36 non-expeditionary men. In the majority of these the pain evidently originated in the muscles of the back or legs, there being 18 cases of myalgia among the expeditionary and 21 among the non-expeditionary cases. In 4 and 8 of the cases respectively the condition was of arthritic nature; and in the remaining 2 and 7 cases respectively the pain was quite definitely referable to the sciatic nerve, commonly the right nerve.

As regards duration, the pains were referred in almost every expeditionary case to repeated wettings in flooded trenches and had lasted several months, usually six to seven months, before admission to hospital. In the non-expeditionary cases the cause and duration were more varied, but some form of exposure was usually blamed. Some cases among the latter were chronic or recurrent for several years, and naturally these proved highly refractory to any form of treatment.

[3] Le Progrès Médical, August, 1915.

From the standpoint of result the 24 expeditionary cases showed in 14 complete cure, this result being attained after an average treatment of five weeks' duration; 7 of the cases were much improved; while 3 were ultimately discharged as medically unfit (d.m.u.) for further service, 2 of these for conditions other than the myalgia. Of the 36 non-expeditionary cases 17 were completely cured after an average treatment lasting three weeks; 12 cases were much improved; and 7 were discharged (5 of these for valvular disease of the heart). One-half of all the cases were thus completely cured, and

TABLE I.—*Expeditionary Cases.*

Case.	Disease.	Length of illness.	Treatment.	Result.
1	General myalgia.	6 months.	8 injns. 16-3-16 to 30-3-16.	Completely cured in July, 1916.
3	Subacute arthritis.	Several months. Treated without improvement at Bath. On crutches. Also malaria.	28 injns. 23-9-15 to 4-11-15; massage.	Walking well without crutches 26-10-15.
4	Arthritis of knee and myalgia with much bending of back.	5 months.	20 injns. 25-10-15 to 13-12-15; soda baths and massage.	Walking smartly and no pain 3-12-15.
6	Sciatica and previous lead poisoning.	Recurrent for 3 years.	6 injns. 22-10-15 to 4-11-15.	Quite well 11-11-15 (blue line on gums).
7	Myalgia of back.	10 months.	6 injns. 22-10-15 to 4-11-15.	Quite free from pains, though legs still weak 8-11-15.
11	,,	5 ,,	2 injns. 29-10-15 to 2-11-15.	Pains gone, though still debilitated 23-11-15.
12	,,	5 ,,	2 injns. 4-11-15 to 7-11-15.	Quite well and returned to duty 15-11-15.
14	,,	2 ,,	2 injns. 31-10-15 to 3-11-15.	Very much better 9-11-15.
15	Mild arthritis in knees and feet.	7 ,,	2 injns. 31-10-15 to 2 11-15.	Pains and swelling completely gone 9-11-15.
18	Myalgia in legs.	6 ,,	4 injns. 9-11-15 to 16-11-15.	Quite cured 23-11-15.
22	Myalgia in back.	4 ,,	4 injns. 29-11-15 to 5-12-15. 14 injns. 14-1-16 to 29-2-16.	Almost well and sent to convalescent home 15-12-15. Readmitted worse 14-1-16 and quite cured 11-3-16.
29	Myalgia in back and legs.	Over 3 months.	14 injns. 17-1-16 to 27-2-16.	Very greatly improved. Later d.m.u. for neurasthenia.
34	Myalgia.	Several weeks.	7 injns. 18-2-16 to 1-3-16. Sod. salicyl. brought down temp. but did not relieve pain.	Returned to duty cured 10-3-16.
36	Myalgia in legs.	Several months.	12 injns. 17-1-16 to 24-2-16; massage.	Returned to duty cured 11-3-16.
40	Subacute rheumatism.	8 months.	Sod. salicyl. 14 days without any effect; then 6 injns. 14-2-16 to 29-2-16; massage.	Pains relieved. Later d.m.u. for neurasthenia.
41	Myalgia.	4 ,,	5 injns. 4-3-16 to 12-3-16.	Returned to duty cured 16-3-16.
43	,,	2 ,,	5 injns. 12-3-16 to 20-3-16.	Cured 25-3-16.
47	Sciatica and subacute rheumatism.	Recurrent for 9 months. Admitted helpless on stretcher.	10 injns. 15-4-16 to 20-5-16; button cautery.	Pains gone; walking with very slight limp 1-6-16.
52	Myalgia in back.	Several months.	10 injns. 8-5-16 to 26 5-16. Soda baths; faradism.	Pains gone and only slight stiffness left 21-6-16.
56	Myalgia in legs.	2 ,,	10 injns. 16-7-16 to 3-8-16; massage.	Returned to duty cured 24-8-16.
59	Myalgia in back and legs.	Several ,,	10 injns. 15-8-16 to 4-9-16; massage.	Very greatly improved 4-9-16.
62	Myalgia, back, legs, and shoulders.	8 ,,	10 injns. 13-8-16 to 31-8-16.	Cured 30-9-16.
63	Myalgia of back.	9 ,,	9 injns. 15-8-16 to 31-8-16.	Very much improved 4-9-16.
65	,,	7 ,,	5 injns. 23-8-16 to 31-8-16. 10 injns. 20-11-16 to 8-12-16.	Previously treated at Buxton 7 weeks without improvement. Free from pain and much less stiff 28-12-16.

D.m.u. = Discharged medically unfit.
V.d.h. = Valvular disease of heart.

TABLE II.—*Non-Expeditionary Cases.*

Case.	Disease.	Duration before treatment.	Treatment.	Result.
2	Myalgia in back and legs.	Recent.	9 injns. 6-2-16 to 22 2-16.	Quite cured by 3-3-16.
5	Recurrent myalgia of back.	20 years. Present attack 3 weeks.	8 injns. 21-10-15 to 4-11-15.	Pain quite gone and returned to duty 10-11-15.
8	Subacute arthritis.	Over 1 year.	5 injns. 2-10-15 to 2-11-15.	Pain relieved, but ultimately d.m.u. for myocarditis.
9	Acute sciatica.	5 days.	2 injns. 28-10-15 to 30-10-15.	Greatly relieved, later quite well.
10	Subacute arthritis.	2 weeks.	3 injns. 29-10-15 to 2-11-15*	Almost quite well 28-12-15.
13	Sciatica r. and myalgia.	Recurrent for 10 months.	5 injns. 7-11-15 to 16-11-15.	Pain gone 23-11-15. Seen again and quite cured 8-4-16.
16	Myalgia in legs and back.	2 months.	3 injns. 11-11-15 to 16-11-15.	Pains almost gone 16-11-15.
17	Sciatica r., severe.	2 ,,	6 injns. 13-11-15 to 9-12-15; massage.	Almost cured. Seen again 5-2-16 and has been quite well.
20	Acute rheumatism.	1 week.	5 injns. 3-12-15 to 11-12-15. Also salicylate of soda.	Joints free by 12-1-16. Later d.m.u. for endocarditis.
21	Myalgia of back.	10 weeks,	2 injns. 3-12-15 to 5-12 15. Also soda baths.	Cured 27-12-15.
23	Subacute arthritis in hips and knee.	Recurrent, 6 months.	4 injns. 29-11-15 to 5-12-15.	Almost quite well.
24	Acute arthritis in wrists and foot.	1 week.	9 injns. 19-11-15 to 5-12-15.	Almost quite well, 5-1-16.
25	Myalgia.	6 months.	10 injns. 29-11-15 to 17-12-15.	Very much improved.
26	Myalgia of back and legs.	6 weeks.	7 injns. 17-1-16 to 29-1-16.	Transferred, somewhat improved, and later fit for duty.
27	Sciatica.	3 months (previously treated for gonorrhœal arthritis).	12 injns. 2-1-16 to 25-1-16; massage.	Very much better.
28	Myalgia, back and legs.	3 months.	9 injns. 14-1-16 to 29-1-16; massage.	Pains relieved. Later d.m.u. for myocarditis from 2 attacks of rheumatic fever.
30	Myalgia in back and legs.	3 weeks.	5 injns. 20-2-16 to 28-2-16.	Cured 2-3-16.
31	Myalgia in back.	Recent.	7 injns. 14-2-16 to 26-2-16.	,, ,,
32	Myalgia.	Several years.	5 injns. 1-12-16 to 9-12-16.	Pains relieved. Later d.m.u. for v.d.h.
33	Myalgia in back.	Treated for gonorrhœa 4 weeks previously.	3 injns. 25-2-16 to 29-2-16.	Cured 4-3-16.
35	Myalgia.	Some weeks.	9 injns. 27-1-16 to 25-2-16; massage.	Almost quite well.
37	Subacute rheumatism.	Some months.	11 injns. 14-2-16 to 10-3-16.	Pains relieved 10-3-16. Later d.m.u. for v.d.h.
38	Sciatica r.	Several weeks.	4 injns. 12-3-16 to 18-3-16. 10 injns. 7-6-16 to 27-6-16.	Very much improved 5-4-16. Recurred and again greatly improved. Finally d.m.u. for gastritis.
42	Pleurodynia.	Recurrent 7 months.	4 injns. 14-3-16 to 20-3-16.	Cured 22-3-16.
44	Sciatica.	7 weeks alcoholic gastritis	8 injns. 10-3-16 to 26 3-16.	Pain gone, still slightly stiff 26-3-16.
45	Myalgia in legs.	3 weeks.	3 injns. 22-3-16 to 26-3-16.	Cured 8-4-16.
46	Myalgia in thighs.	5 ,,	8 injns. 22-3-16 to 23-4-16.	Cured 29-4-16.
48	Myalgia in legs.	3 ,,	4 injns. 23-4-16 to 4-5-16.	Cured 5-5-16.
49	Sciatic r. severe.	Foll. 6 months after acute rheumatism.	10 injns. 4-5-16 to 22-5-16; button cautery.	Cured 24-5-16.
50	Myalgia in back.	Several weeks.	10 injns. 20-5 16 to 7-6-16; button cautery.	Greatly improved 21-6-16.
51	Myalgia in back and legs.	Since childhood.	10 injns. 30-5-16 to 17-6-16.	Not much improved. Later d.m.u.
53	Myalgia in thigh.	Several weeks.	10 injns. 13-6-16 to 1-7-16.	Returned to duty cured 1-8-16.
54	Acute rheumatism.	Third attack.	10 injns. 23-6-16 to 11-7-16.	Pains quite gone 4-8-16. Later d.m.u. for v.d.h.
55	Subacute arthritis.	Recurrent 27 months.	10 injns. 18-7-16 to 5-8-16.	Cured 4-8-16.
61	Myalgia in back and legs.	Recurrent 3 years.	10 injns. 13-8-16 to 31-8-16.	Quite cured 20-9-16.
67	Myalgia in legs.	Recurrent several years.	5 injns. 7-10-16 to 15-10-16; massage; faradism.	Very much improved 23-10-16.

* Injections stopped because of reaction with eruption.

one-third were very much benefited, but passed out of observation before it could be determined whether they would become quite free of their trouble.

The method of treatment finally adopted was to keep the patient in bed for the first fortnight, and to give the colloidal sulphur (beginning with 1 mil. dose and rising to 2 mils. if no reaction took place) every second day for three weeks. With this were combined massage on the alternate days, and occasional hot alkaline baths. Commonly there was no general or local reaction, but in some cases the temperature rose about 2° on the day after an injection; and now and then a painful swelling developed at the site of the injection, which was, however, readily dissipated by massage.

Conclusions.—1. Intramuscular injections of colloidal sulphur are of the very greatest value in the treatment of subacute painful conditions in the muscles and joints. 2. The most satisfactory course of treatment consists of an injection administered every second day for three weeks (10 injections), combined with rest and with massage on the intervening days. 3. In the greater number of subacute cases, lasting several months, complete recovery may be expected after three to five weeks from the commencement of the treatment. 4. This method is also very helpful in lingering cases of gonorrhœal rheumatism. 5. It does not, however, take the place of salicylate of soda in relieving the pains of acute articular rheumatism.

Edinburgh.

THE EFFECT OF VACCINIA ON THE WELL-BEING OF CHILDREN

AS JUDGED BY THEIR REACTION TO SUBSEQUENT INFECTIONS.

BY J. PARLANE KINLOCH, M.D. GLASG.,
LECTURER IN PUBLIC HEALTH, UNIVERSITY OF ABERDEEN.

THE immediate injuries and complications resulting from vaccination have been very fully discussed in the literature of the subject. It would appear that while the infectious disease vaccinia is mild, danger lies in the possible infection of the open wound, and that improved quality of vaccine virus and use of aseptic methods have greatly diminished this risk.

It has been alleged, however, that the constitutional disturbance produced by vaccination in the first year of life cannot be regarded as other than serious, since the effect of any mild infection at that tender age can gravely prejudice the child's future growth and diminish its resistance to disease. So far as I am aware, no information on this point has been published, and it has seemed that some evidence might be obtained by observing the effects of other infectious diseases in vaccinated as compared with unvaccinated children.

Accordingly a record has been kept of the presence or absence of vaccination scars on all children under 5 years admitted to the City of Glasgow Fever Hospital, Ruchill, during the years 1910 to 1913, and the accompanying tables show the incidence of death and of complications among the vaccinated and unvaccinated suffering from scarlet fever, diphtheria, measles, and whooping-cough. Tables for erysipelas, broncho-pneumonia, and enteric fever have also been prepared, but in these diseases the number of cases is so small that only total numbers are submitted. It may be stated that when doubt existed as to the presence or absence of vaccination scars friction was applied to the skin, and only those cases were regarded as vaccinated in which scar-tissue stood out pale against the hyperæmic skin.

In Table II. are given: (1) the number of children under 5 years of age admitted to hospital during the three years' period; (2) the death-rates among the vaccinated as compared with the unvaccinated in each of the diseases; and (3) a comparison is made to differentiate male and female children.

Age.—The number of cases is too small to allow of any useful information being derived from the figures relating to the different age periods. The mortality in the following age periods may be mentioned:—

Of scarlet fever cases in third year 9·4 p.c. of v. died, unv., 8·6 p.c.
,, diphtheria ,, fourth ,, 11·8 ,, ,, ,, 15·6 ,,
,, measles ,, second ,, 17·0 ,, ,, ,, 23·2 ,,
,, whooping-cough cases in first ,, 41·9 ,, ,, ,, 41·3 ,,

Convulsions provided a terminal symptom in the whooping-cough cases in which death was not accounted for by any of the tabulated complications.

V, vaccinated. Un., unvaccinated.

Complications.—Again, if the prevalence of complications in the several diseases be considered, the following figures are obtained:—

Of scarlet fever cases	32·6	per cent.	of v.	developed	complications.	
,, ,,	37·6	,,	,,	of unv.	,,	,,
Of diphtheria ,,	11·2	,,	,,	of v.	,,	,,
,, ,,	17·5	,,	,,	of unv.	,,	,,
Of measles ,,	22·2	,,	,,	of v.	,,	,,
,, ,,	28·4	,,	,,	of unv.	,,	,,
Of whooping-cough	23·5	,,	,,	of v.	,,	,,
,, ,,	29·4	,,	,,	of unv.	,,	,,

And this constant predominance of complications among the unvaccinated is similarly distributed if the cases are subdivided into males and females.

Finally, if the most frequent complication in each disease is separately examined it is found that there developed—

Septic complications in scarlet fever in	26·9	p.c. of v.,	in	30·4	p.c. of unv.	
Diphtheritic paralysis in	6·5	,,	,,	7·3	,,	,,
Lung complications in measles in ...	14·5	,,	,,	18·6	,,	,,
,, ,, in whooping-cough ...	19·6	,,	,,	22·5	,,	,,

Discussion and Conclusion.

The figures deal with 3804 cases of infectious diseases, of which 3058 were vaccinated and 746 unvaccinated, and they show repeatedly an increase in the incidence of disease complications and death among the unvaccinated. A larger number of cases will have to be examined before this point can be regarded as generally proved.

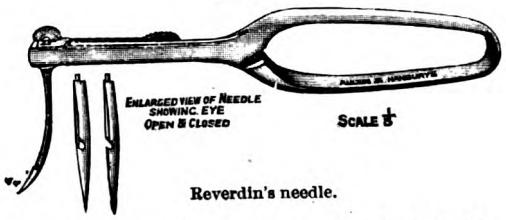
It is not contended that vaccinia increases the resistance of the body to disease in general. The results obtained in this inquiry must depend in part on the inclusion among the unvaccinated of weakly children exempted from vaccination on purely medical grounds, and this inclusion may be sufficient to explain the increased vulnerability of the unvaccinated group. On the other hand, the healthy children of conscientious objectors to vaccination appear in the unvaccinated group, and the increase in the number of these children during recent years is shown in Table III., for which I am indebted to Dr. A. K. Chalmers, medical officer of health of Glasgow.

TABLE III.—*Glasgow: Statement of Number of Declarations of Conscientious Objection to Vaccination in Relation to the Births Registered.*

Year.	Births.	C.O.*	Per-centage.	Year.	Births.	C.O.*	Per-centage.
1907	23,926	474	2·0	1911	21,584	3791	17 6
1908	23,743	2183	9·2	1912	21,812	4371	20·0
1909	23,002	2653	11·5	1913	28,688	6804†	23·7
1910	22,014	3231	14·7	1914	29,455	7580	25·7

* Conscientious objectors. † Extended city.

Whatever be the explanation of the figures submitted, the fact remains that they afford no evidence that vaccinia has a prejudicial effect on a child's future well-being as judged by its response to subsequent infection. I have pleasure in acknowledging my indebtedness to Dr. John Brownlee, statistician to the Medical Research Committee, for suggesting this investigation and placing the information at my disposal.



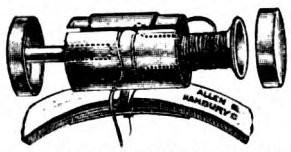
COUNTY OF ABERDEEN: REPORT OF TUBERCULOSIS MEDICAL OFFICER FOR 1916.—The report for 1916 of the tuberculosis medical officer for the county of Aberdeen states that during the year 393 cases were notified, the death-rate running almost parallel with that for the whole of Scotland. The doubts once entertained as to the advisability of the compulsory notification of tuberculosis have proved groundless. Notification has not led, as was feared, to sufferers from the disease being regarded as lepers. Occupation did not form an important factor in the incidence of the disease; heredity, defective housing, and malnutrition were found to be much more important factors. The report strongly condemns box-beds, and regards the housing problem as perhaps the most outstanding of the many difficulties associated with the eradication of tuberculosis. Among school children tuberculosis was found to be fairly prevalent, the usual site of the disease being at the root of the lungs, where the bronchial glands became affected. The report emphasises the need of after-care committees, and states that, on the whole, the expenditure under the county council scheme has been justified and has borne good fruit.

ON THE SOLE USE OF REVERDIN'S NEEDLE.

BY VICTOR BONNEY, M.S., M.D., B.SC. LOND., F.R.C.S.,
SURGEON TO THE CHELSEA HOSPITAL FOR WOMEN AND TO THE MILITARY BRANCH OF THE MIDDLESEX HOSPITAL AT CLACTON; ASSISTANT GYNÆCOLOGICAL SURGEON TO THE MIDDLESEX HOSPITAL, ETC.

THE subject of how to save time in surgical operations is always important, and I am therefore venturing to describe a method of general operative technique which I have employed to that end for nearly four years. It turns upon the sole use of Reverdin's needle. (Fig. 1.) The needle in question, which, it may be recalled, has an eye that can be opened and closed by means of a slide, is employed in this country, but to nothing like the same extent as in France, where it is the only needle in common use. Its great advantage is that it renders a second assistant to thread the needles unnecessary, for they are threaded by the first assistant, and he and his chief are therefore in this particular self-contained.

FIG. 1.



Reverdin's needle.

The Use of Reverdin's Needle.

For those who are not accustomed to this needle it may be remarked that its use requires a little practice. There is a tendency at first to open the eye whilst passing it through the tissues, especially if these are resistant, or to forget to close it before drawing it back, either of which mistakes causes the needle to catch in and lacerate the tissues, while the needle itself is very likely to be damaged.

Another and very important point concerns the assistant who threads it. Unlike a *notched* needle, in which a degree of tension must be kept upon the suture during the withdrawal of the needle, the assistant, once he has placed the suture in the eye and the slide is closed, *must let the suture go loose.* If he pulls upon it, the withdrawal of the needle is rendered jerky, and the slide that closes the eye is liable to be injured.

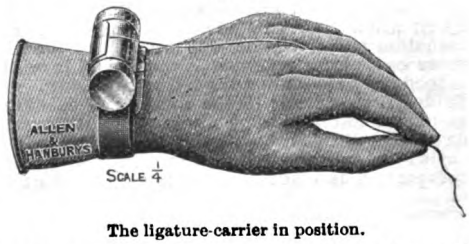


FIG. 2.

The author's wrist-ligature carrier.

The whole instrument is a delicate one; this is its drawback. The needles, which are detachable from the holder, require to be carefully looked after. They must be taken to pieces immediately after use, cleaned, boiled, and then stored in absolute alcohol, in which they will not rust.

FIG. 3.

The ligature-carrier in position.

The surgeon should have two sizes of needles, each in its separate holder, one being very fine for delicate suturing such as is required in intestinal anastomosis, and the other a coarser one for ordinary use.

Carriage of the Suture and Ligature Material.

In Paris I saw the suture material provided for in several ways. Thus, the surgeon carried in his left hand a sheaf of

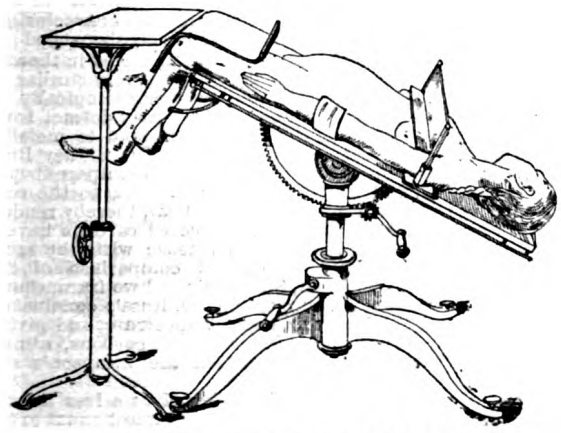
ready-cut lengths; or the assistant cut off the lengths as he required them, from a reel placed near him. None of these methods seemed to me to be ideal, and I therefore devised the wrist ligature-carrier shown in Fig. 2. It consists of a little cylindrical metal box, opening at either end, in which is contained a glass reel on which the ligature material

FIG. 4.

Catgut on a reel.

is wound. The cylindrical box is attached to the wrist by means of a broad red rubber band in a similar manner to a wrist-watch. (Fig. 3.) This carrier is not only useful as a means of providing suture material with which to thread the Reverdin needle, but is a great time-saver when the surgeon has to ligature a number of vessels one after the other, as, for instance, in amputation of the breast. To use it most advantageously he should be able to tie the single-handed knot with equal facility with either hand. When operating I wear one of these carriers on either wrist, and my assistant does likewise. We are thus absolutely self-contained, having all the suture and ligature material we require in front of us.

FIG. 5.



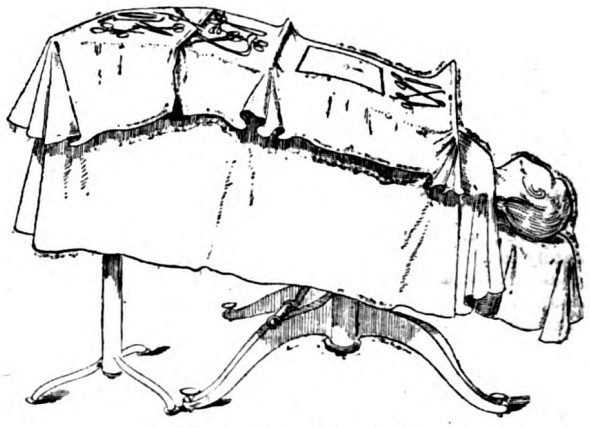
The author's "single-hand" scissors.

Any material the surgeon fancies may be wound upon the glass reel inside the carrier. Messrs. Allen and Hanburys put up at my suggestion a "tanned" catgut, wound on reels that fit the carrier. (Fig. 4.) Each reel, immersed in iodine solution, is contained within a glass tube, in which it is sterilised by superheating. The reel carries double the length of catgut that is contained in the similarly sterilised hank. For all purposes catgut is better wound on a reel, for hanks are troublesome to unravel, and in the process the catgut is often brought dangerously near to unsterilised areas.

Threading, Tying, and Cutting the Sutures.

The assistant threads the needle from one of the four carriers, according to the kind of suture material required.

FIG. 6.

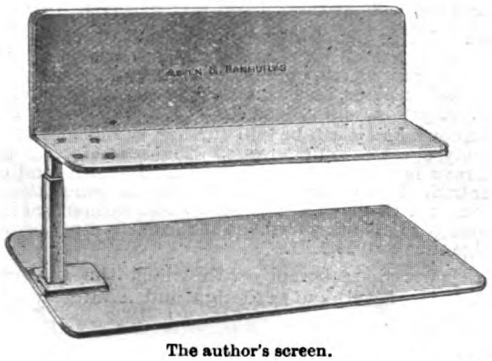


The knee table, screen, and elbow table in position.

The tying of the suture should be done either by the surgeon or the assistant, according to the side of the table from which the tying may be most satisfactorily and expeditiously accomplished. A large number of operative manipulations are best carried out from the assistant's side, and should be so effected. This, of course, postulates an able assistant. One great advantage of the technique I am now describing is that it makes for "team work."

Whilst the assistant is tying the suture the surgeon is passing the needle for the next one; and as he can do this quicker than the knot can be tied, he should cut the suture short himself, for otherwise an interval will elapse during which he is doing nothing. To avoid having to drop the Reverdin needle which he holds in his right hand or the dissecting forceps which he holds in his left, I have devised the scissors shown in Fig. 5. These scissors can be held in either hand in such a way as to leave the index finger and thumb completely free. The handles are gripped between the thenar and hypothenar eminences, and the shanks pass pass out *through the cleft between the index and second fingers.* They save much time otherwise consumed in picking up and laying down.

FIG. 7.



The complete arrangement.

Arrangement of the Tables and Disposition of the Instruments.

In order to complete the technique it is necessary to have the instruments and swabs so placed that neither the surgeon nor his assistant need turn away from the operating table to get them. To achieve this I employ the following arrangements in all cases of abdominal section for pelvic or lower abdominal disease. The patient is in the tilted position. On her knees is hung my "knee-table," shown in Fig. 6, which consists of a plate of thin metal bent across its middle to nearly a right angle and having a flange at one end. This device, when covered by the sterilised body-sheet, forms an excellent table on which instruments may be placed without slipping down between the thighs or into the abdomen. (Fig. 7.) Towards the head of the patient is placed the screen which I devised, shown in Fig. 8. It has projecting from it a ledge, which also forms a little table on which instruments can be placed. The screen and the knee-table having been placed in position, a sterilised body-sheet is laid over all, and an elbow-table on which are the instruments and swabs ready laid out is now brought up to the knee-table so as to extend its area. (Figs. 6 and 7.) A continuous sterile surface is thereby formed, the only break in

FIG. 8.

The author's screen.

which is the aperture left in the sheet for access to the site of the wound.

This aperture is the weak spot in an otherwise aseptic "operating bench," for the skin cannot be absolutely sterilised. To meet this difficulty, sterilised gauze, linen, or rubber sheets are attached to the edges of the wound in the usual way. The ideal would be to cover the skin with an absolutely impermeable sterile varnish which would remain perfectly adherent throughout the operation. I have tried to make such a varnish, but hitherto without success, although I have used a large number of substances; they all tend to peel off at the wound edges. The use of "crystal violet" as a means of providing a permanently sterile surface to the skin during an operation promises a solution of this difficult problem.

Conclusion.

The technique I have described requires a little practice, and an assistant trained in it; but these attained, it markedly facilitates and expedites operating. The mere fact of not having to turn round lightens and quickens the work; while the having of all one's appliances immediately to hand, and not being obliged to give orders or make requests to an assistant standing behind one's back, removes a potential source of irritability and impatience.

Devonshire-place, W.

ULTRA-VIOLET RADIATION:

A SPECTROSCOPIC INVESTIGATION OF SOME SOURCES OF ULTRA-VIOLET RADIATION IN RELATION TO TREATMENT BY ULTRA-VIOLET RAYS.[1]

BY CHARLES A. SCHUNCK, F.C.S.

As ultra-violet radiation is extensively used therapeutically I thought that a spectroscopic comparison of some of its sources, showing their constituent radiations, wave-lengths, and relative intensities, and the attempt to ascertain the most efficient for the purpose, would be of interest and value.

After describing the regions of the spectrum the following table was given:—

The Spectrum Regions.

Visible region ...	7594–3934 A.U.	† Lyman region ...	1230–600 A.U.
Ultra-violet region	3934–1850 ,,	Unexplored ,, ...	600–8 ,,
* Schumann ,,	1850–1230 ,,	X and Gamma ray...	8–0·07 ,,

* Schumann substituted fluorite for quartz and adopted a vacuum spectroscope to avoid absorption of the rays.

† Lyman in 1914, using a concave grating (dispensing with necessity of lenses) enclosed in a brass tube 11 cm. in diameter and over a metre long containing hydrogen at a pressure of 2 to 3 mm. and using a strong disruptive discharge through a discharge tube, was able to extend the spectrum to λ 900; and in 1915, by substituting He free from N for H and giving an exposure of about 10 minutes, repeatedly observed a number of new lines, the most refrangible of which was λ 600.

From λ 600 to about λ 8, where the softest characteristic X rays of Al have been recorded, is an unexplored region, the region where that profound change from light radiation to X ray takes place, and which, when means are devised for its investigation, may lead to most important results. Lyman considers it can be still further extended below λ 600 by purely spectroscopic means.[2] The wave-length of the soft X rays is of the order of 1 Angström unit and of the harder 0·25. The value 0·07 is for the most penetrating rays from radium C, given me by Sir Ernest Rutherford in 1915, who also gave his measurement of the hardest rays from the Coolidge tube as 0·14 A.U.

The Quartz Spectrograph, with which the spectra were recorded, is of well-known design and admirably adapted for the purpose.

The one completed for me last year by Messrs. Bellingham and Stanley, of 71, Hornsey Rise, has various improvements upon the original model of A. Hilger and Co., from whom I had one of the first in 1908. The salient features are its compactness, the complete enclosement of the prism, and lenses able to take the entire spectrum from the extreme red to the ultra-violet at λ 2100 on one plate 10 inches long in excellent focus throughout; when once set no further adjustment is required. [A description of the instrument was here given.]

For the arc spectra the voltage was 100, and the amperage was varied from 5 to 10. For each plate the amperage and exposures for each spectrum thereon were kept constant so as to get comparable results. The exposures in the arc spectra varied from 5 to 15 seconds, whereas the corresponding spark spectra took 2½ to 5 minutes. The plates used were Wratten and Wainwright pan-chromatic and the sources were compared on the same plate. The various sources were examined both in the arc and spark discharge, though the latter is hardly applicable therapeutically in general, the spark only being a point of light compared to the arc, and to be at all practicable would have to be condensed and then but a very small area would be covered. This might be useful in some cases, however.

The Sources of Radiation.

The sources of radiation examined consisted of—

Metallic electrodes of pure[3] W, Mo and Fe; ¼ inch carbon rods impregnated by boiling in solutions of sodium tungstate, uranium nitrate, ammonium molybdate, and titanous chloride; and ¼ inch cored carbons filled with U_3O_8, Fe_2O_3, wolfram (75 per cent. WO_3, 20 per cent. FeO, 5 per cent. MnO), the ore of tungsten, and pure W and Mo (99 per cent.) in the form of powder, together with the Simpson electrodes which are said to consist of wolfram. These are very unsteady in the arc, splutter badly, and a glassy deposit forms on the electrodes that has to be removed before the current will pass again, whereas the above carbons are quite steady, which is a great advantage.

The reason for trying the impregnated and cored carbons was the readiness one can assimilate any substance for the arc discharge and the endeavour to get, if possible, a more intense and cheaper source in this manner than the Simpson's or metallic tungsten. From the spark spectra experiments I had high hopes that the carbons impregnated with uranium nitrate and ammonium molybdate[4] would prove an excellent source, and rival that of W, whose spectrum is of a similar character. But though it has a more intense spectrum than W in the spark and of greater extent, it falls off considerably after λ 2500 and ends at λ 2300, compared to W in the arc, which extends to λ 2200 on this plate. W also appears to be more intense in the arc than the spark.

The Spectroscopic Results.

The following are the spectroscopic results obtained:—

The most intense and richest source of ultra-violet radiations is that of the W metallic electrodes in the arc. The spectrum[5] consists of very many lines of nearly equal intensity throughout the ultra-violet spectrum, so close together as to form an almost continuous spectrum extending with but slight loss of intensity to λ 2130 (the limit of the instrument). The W spectrum and the Simpson electrodes extend further with the same amperage and exposure than any of the sources examined.

The Mo arc spectrum is of a similar character but not so intense throughout, extending to λ 2190 but losing in intensity at λ 2300. The Fe arc spectrum is very rich in ultra-violet radiations, and though containing some very intense groups of lines is not so uniform throughout as that of W and extending only to λ 2250. Its spark spectrum is characterised by a maximum of intensity in the neighbourhood of λ 2400, which maximum λ2500 is not so pronounced in the arc.

The spectrum of the Simpson electrodes is very similar in character and of the same intensity spectroscopically as that of the W arc, but their unsteadiness may detract from their effectiveness therapeutically as compared to metallic W electrodes with treatment exposures. Dr. Sidney Russ was the first to examine the spectrum and to compare it with that of pure W, and he pointed out and came to the conclusion that they were apparently identical, thereby rendering a signal service. The wolfram cored carbons have a similar spectrum, but it is not so intense with the same ampèrage and exposure. A careful comparison of the spectra of metallic tungsten, Simpson's and wolfram, shows that though very similar, supporting Dr. Russ's conclusion, yet there are differences from the W spectrum, and giving an increased amperage to the wolfram carbons, almost an exact match is obtained between the Simpson's and them.

Of the cored carbons the W powder gives a less intense spectrum than the W electrodes. Fe_2O_3 almost equal to the

[3] W = Tungsten, Mo = Molybdenum, Fe = Iron, Ti = Titanium, U = Uranium, Mn = Manganese, C = Carbon.

[4] Known as the "Jones electrodes," and used as a source of light for recording absorption spectra in the ultra-violet, as the lines are so numerous and close together as to form almost a continuous spectrum.

[5] Shown at a meeting of the society last year by Messrs. Morphy and Mullard in their paper on "The Enclosed Tungsten Arc," and also by Major Wilson, C.A.M.C., when describing "a new tungsten arc lamp" he has devised.

Fe electrodes with advantage of steadiness which the latter lack, as they scintillate considerably. Mo powder like the Mo electrodes consisting of many lines extending to λ 2300, but not nearly so intense. The U_3O_8 was disappointing, and better results were to be expected. The oxide, however, was not reduced to the metallic state by the arc discharge which may be the cause, and shortly I hope to be able to examine the arc spectrum of metallic uranium electrodes. The spectrum loses intensity at λ 2600, but, so far, the lines are much closer together than W, and the spectrum more intense. The numberless lines and their closeness, both in the arc and spark spectrum of U, is its great characteristic.

The impregnated carbons in the spark are much more intense than in the arc. The uranium nitrate and ammonium molybdate impregnation gives a magnificent intense, almost continuous spectrum extending to λ 2300 without much loss of intensity, and is the most intense and richest in ultra-violet radiations of any spark source. The carbons impregnated with sodium tungstate were not nearly so continuous or intense. In the arc as far as λ 2500 the carbons impregnated with uranium nitrate and ammonium molybdate are more intense and continuous than the W arc, but their spectra do not extend as far, λ 2300 being about the limit. The sodium tungstate and titanous chloride impregnation are particularly poor. The same impregnated carbons were used both for the spark and arc.

Radiations of the sources used in treatment.—By comparing the arc spectra of carbon, the iron spark and arc, the mercury vapour arc, the Simpson electrodes and metallic tungsten in the arc, the nature of the radiations, and the intensity of the various sources that have been and are used in ultra-violet radiation treatment are seen.

Carbon is the source used in the Finsen lamp, the spectrum being very poor in ultra-violet rays and the exposure as long as 70 minutes at a time. After the Finsen lamp, I believe both the iron arc and spark were used, the latter with a quartz condenser with exposures of 3 minutes. Then the mercury vapour arc as in the Kronmeyer lamp, with a quartz condenser as a compressor on the skin, with exposures of 3 minutes or thereabouts. The spectrum consists of intense isolated bands and lines, the most intense and broad of all being just inside the Schumann region at λ 1849·6. A year ago the Simpson electrodes were the vogue until Major Turrell adopted metallic tungsten, with which the maximum exposure is 5 minutes without a condenser.

In regard to filament lamps, like the spectrum of all incandescent solids, the spectrum which is a continuous one falls short of λ 3000, so they are hardly suitable for ultra-violet radiation treatment where radiations of shorter wave-length are the effective ones therapeutically, as I believe I have been able to prove.

Therapeutical Experiments.

Through the valuable advice and assistance of Major W. J. Turrell, R.A.M.C., electro-therapeutic physician to the Radcliffe Infirmary, Oxford, to whom I am much indebted for the therapeutical aspect of ultra-violet radiation, I have been able to make some simple therapeutical experiments of the more intense sources.

Major Turrell [6] finds that the W arc (he was the first to apply this source) is the most efficient source clinically of ultra-violet radiation and superior in results obtained from the Simpson electrodes, which is supported by the spectroscopic examination. Within certain limits, he states, the intensity of the erythema produced on the skin in a given time may be taken as measuring the clinical efficiency of the radiation of the source. The open W arc he places 1 foot from the part to be treated, giving an exposure of 5 minutes with an ampèrage of 5 to 10, voltage 100, as the maximum dose.

The following experiments were undertaken :—

In conjunction with him my forearm was exposed for 5 minutes at a distance of 12 inches with a current strength of 5 ampères over different areas of the skin to the action of the electrodes in the arc, of metallic W, Simpson's and half inch cored-carbons filled with U_3O_8, W powder, wolfram and Fe_2O_3. The cored-carbons, which burned very steadily, gave no erythema. The W a fair reaction and the Simpson's slight in 12 hours; the former gave a slight redness in 2 hours, the latter very slight in the same time.

To get an increased effect I used the quartz cylindrical condenser under the same conditions as the spectra were taken, which forms an image of the arc 16 inches from the condenser in the form of a band about ½ inch wide on the skin of the forearm, the arc source being 3½ inches from the condenser. The current strength, voltage 100, was 9 to 10 ampères and the exposures about 2 minutes. An intense erythema was produced in a few hours with metallic W (indication in half an hour), not quite as much with the Simpson's (indication in 1 hour), and fairly intense with metallic Fe electrodes and the carbons cored with wolfram (indication in 2 hours). The exposure in this case was 2½ minutes, ampères 10. Using W as one electrode and a soft-cored carbon the other, alternately as "positive and negative," compared to W as both electrodes, there appeared but little difference in the erythema produced. With W as the positive electrode the arc is much the steadiest, and very steady indeed. The three spectra at 9 ampères and 10 seconds' exposures showed very little difference in intensity, W the best, then W as the positive electrode. Carbons impregnated with uranium nitrate and ammonium molybdate, 9 ampères and 4 minutes' exposures, gave a faintish erythema in 24 hours, but no reaction with an exposure of 2 minutes.

One mm. thickness of glass in front of the condenser with an exposure of 4 minutes at 9 ampères gave no reaction to the W arc, neither was there a reaction with a piece of microscopic cover-glass in front, whereas the W arc with 2 minutes' exposure gave a good redness on the skin in 12 hours. These cover-glass experiments were repeated several times, and there was no difference if the glass was placed on the skin. Only in one experiment was there a slight reaction with 2½ minutes' exposure and 10 ampères, and in this experiment I am not certain whether the glass was covering the lens completely. The 1 mm. glass and the cover-glass tested spectroscopically under the same conditions as the erythema experiments were made, cut off the spectrum at λ 2950 and λ 2750 approximately.

This shows, I think, fairly conclusively that radiations of λ 2750 approximately and upwards have no therapeutical value as judged by the erythema effect, whereas if the one experiment is correct there is an effect between λ 2750 and λ 2950. It must be remembered these experiments were only made upon my own skin ; still, an exposure of 4 minutes to the W arc with the condensing lens is a very severe test, seeing that in the arc experiment of 2½ minutes at 10 ampères the erythema was so intense that it persisted for three weeks, the skin desquamating and causing a fair amount of irritation.

Dr. Sidney Russ [7] last year stated that the skin is very absorbent to A.U. radiations.

A piece of skin from the human abdomen 1/10 mm. thick placed in front of the slit of the spectrograph with the Simpson arc 20 cm. distant and giving an exposure of 2 minutes, cuts off the spectrum approximately at λ 3000, showing that ultra-violet radiations between λ 3000 and λ 2100 are very easily absorbed by the human skin, and this is the *same* region I find of therapeutical value. "With thickness of ¼ mm. and 1½ mm. of skin and an increased exposure of 8 minutes the radiations between λ 3000 and λ 3800 were transmitted, but he considers it is doubtful whether more than 1 per cent. of the radiation penetrates as deep as 1 mm."

These two sets of experiments tend to show that the therapeutical effect is limited to the superficial tissues, and this is also the opinion of Major Turrell from the clinical aspect, who states in the paper above mentioned that "the therapeutical value of ultra-violet radiation appears to be due to its destructive action on micro-organisms and to the active hyperæmia which it induces in the superficial tissues."

I have also proved while constantly working with the W arc in this research, that a sheet of 1½ mm. glass placed between the arc and the face is a perfect protection from the effects of the radiations, especially to the eyes, which are particularly sensitive, which is supported by my own experience, my eyes being much affected before adopting this means of protection. During one day's experiments I calculated I was subjected for half an hour to the W arc 1 foot away, and with this simple protection there was no effect on the eyes or skin.

I think one can safely assert that the radiations of therapeutic value lie between λ 3000 and λ 1850, and I am now endeavouring by spectroscopic means to ascertain which part of this region has the greatest therapeutic efficiency. The W arc is no doubt the most intense source of radiation there is at present for the purpose. The open arc can be increased in intensity by using a quartz condensing lens, the absorption of which for these radiations is but slight. Pflüger for a piece 1 cm. thickness gives the values of

[6] Ultra-violet Radiation from the Tungsten Arc, Section of Electro-Therapeutics of Royal Society of Medicine, Oct. 20th, 1916 ; THE LANCET, 1916, ii., 790.

[7] From the Visible to the Gamma Ray Spectrum, Brit. Med. Jour., Jan. 22nd, 1916.

5·8 per cent. at λ 2200, 8 per cent. at λ 2140, 16·4 per cent. as λ 2030, but as much as 32·8 per cent. as λ 1860; while Collentz finds that throughout the spectrum to λ 2500 it is almost perfectly transparent in thicknesses up to 3 cm. If a reflecting mirror is used,[8] then platinum and nickel will be found superior to silver, and silicon the best of all reflecting surfaces. Silver reflects on an average 30 per cent. of the radiations between λ 3000 and λ 2000, platinum and nickel about 45 per cent., but silicon as much as 76 per cent. Mirrors of these substances can be readily prepared by cathode spluttering or electro-plating.

I have to thank Dr. Oberlander, Ph.D., Mr. J. C. Gardiner, F.C.S., and Mr. Arthur Schiff for the pure substances experimented with, and I am much indebted to Professor W. H. Perkin, F.R.S., for so kindly giving me the facilities of carrying on part of this investigation at the New Chemical Laboratories at Oxford.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF
ACUTE INTESTINAL OBSTRUCTION BY MECKEL'S DIVERTICULUM
SUCCESSFULLY TREATED BY LAPAROTOMY.

BY E. MANSEL SYMPSON, M.D. CANTAB., M.R.C.S.,
HONORARY SURGEON, LINCOLN COUNTY HOSPITAL; LIEUTENANT-COLONEL, R.A.M.C. (T.F.), 4TH NORTHERN GENERAL HOSPITAL.

As cases of Meckel's diverticulum are not common, and those of intestinal obstruction thereby still less so, the following notes may be of interest.

The patient, a thin lad of 21, was admitted to the Lincoln County Hospital on May 1st last with acute intestinal obstruction. Two years previously he had an attack of acute peritonitis. An operation was performed at a naval hospital, where the abdomen was opened in the middle line, and drained. Two days before admission to the County Hospital he was suddenly seized with acute pain over the whole abdomen, of a spasmodic type, followed by persistent vomiting, which in 12 hours' time became definitely stercoraceous. Constipation had been absolute from the start. On admission he had well-marked "facies hippocratica," furred tongue, with foul breath smelling strongly fæcal. Temperature 97° F.; pulse-rate 130, of poor volume and feeble. Over the abdomen respiratory movements almost universally absent, distension and tympanites were evenly distributed all over, well-marked "ladder" pattern, and peristalsis visible synchronous with exacerbations of pain. The abdomen was universally rigid and tense, with no specially tender spot or any localising sign. A provisional diagnosis of "strangulation by bands" was made. A middle-line incision about 5 inches long was made partly in the line of the old scar. At first sight of the contents of the abdomen the condition appeared hopeless, as the much-distended ileum and jejunum were bound up by very numerous adhesions, some well organised and of old standing, but the majority of only recent date. A thorough and systematic division of adhesions was made and the freed gut, after examination, was returned into the peritoneal cavity, but the bowel was still distended. It was noticed that although by far the greater part of the small intestine was obviously obstructed, yet the portion of it just above the ileo-cæcal junction was flaccid and of ordinary size and appearance. This part of the bowel was traced upwards for about 2 feet, where a Meckel's diverticulum was found, about 4 inches long, which was adherent at its tip to the posterior abdominal wall and to the root of the mesentery opposite the body of the second lumbar vertebra, thus forming an open small window, through which about 2 feet of ileum had become prolapsed and strangulated. The implicated bowel was in fairly good condition, so the diverticulum was removed on similar lines to an appendicectomy, and the abdomen was closed. The after-treatment consisted in administration of 1 c.c. of pituitrin 8-hourly, calomel (gr. 1) every hour for 10 hours, and frequent injections of brandy and saline fluid. On the second day the bowels were well opened, and the patient was back on a full diet on the fifth day. Convalescence was uninterrupted and he was discharged cured and entirely relieved on May 29th, four weeks after admission to hospital.

I am much obliged to Mr. W. F. Stiell, our resident medical officer, for these notes and for help at the operation.

A CASE OF SUPRAPUBIC HERNIA.

BY WILLIAM H. FORSHAW, F.R.C.S. ENG.

CASES such as the one here described are of exceptional rarity. The only one I know of was described by Voeckler[1] in 1912.

A married woman, aged 41, with one child, aged 15 years, was recently admitted into the London Hospital. On the day before admission she, whilst in the act of micturition, suddenly felt a sharp pain just above the symphysis pubis. On examination of the region she discovered a lump which had never been noticed before. The pain of the swelling was intense and caused her to vomit every half hour, until she was admitted into hospital some 24 hours later. Her condition on admission was as follows: There was a hard, rounded swelling about the size of a doubled forefinger situated immediately above the symphysis pubis in front of the right rectus muscle, which was painful to the touch and gave no impulse on coughing. It was thought to be an interstitial inguinal hernia, but at the operation was found to be a strangulated hernia emerging from the abdominal cavity between the two recti muscles very near to their insertions. The sac was firmly nipped at the neck, and only with great difficulty could the director and knife be inserted. The constriction was divided in an upward direction—towards the umbilicus—to avoid danger of damage to the bladder. The gut was returned and the sac cut away. The stump was transfixed and sutured to the deep surface of the right rectus muscle. The patient made an uninterrupted recovery.

It is interesting to note that the patient also has a reducible left femoral hernia of three years' standing.

I am indebted to Mr. H. M. Rigby for allowing me to publish this case.

London Hospital.

A CASE OF ANTRAL ABSCESS TREATED WITH SALICYLIC ACID.

BY PERCY R. WILDE, M.D. ABERD.,
PHYSICIAN, LANSDOWN HOSPITAL, BATH.

ANTRAL abscess is often a very troublesome condition, and the following long-standing case in which the treatment adopted proved efficacious in stopping the discharge may prove suggestive.

The patient was an elderly lady with an abscess of the antrum which had existed for fourteen years. During this time the tube had been removed every night and morning and the cavity syringed with an antiseptic solution. Guided by the principle that all chronic discharging surfaces should be kept dry, and knowing that salicylic acid is one of the most powerful bactericides we possess, I treated her by plugging the antrum with a piece of gauze into which I had rubbed a powder consisting of salicylic acid one part and saccb. alb. four parts. This was passed loosely into the cavity and renewed daily. On the fourth day the discharge had ceased. Treatment was then suspended, a piece of cotton wool being placed over the opening of the sinus, which was kept in position by the denture the patient was wearing.

The treatment was effective. Three months later the patient reported that she had had no further trouble from the day of the last plugging.

Bath.

SECTION OF ANATOMY AND PHYSIOLOGY.

Perfusion of the Frog's Heart with Nicotine.—Modification of Fatty Compounds in Intestinal Epithelium.

A MEETING of this section was held on May 25th, Professor D. T. BARRY, the President, being in the chair.

The PRESIDENT read a paper on Perfusion of the Frog's Heart with Nicotine. He said that hitherto nicotine effects on the heart were chiefly investigated by dropping on the drug diluted without neutralisation. The results of perfusion after neutralisation were much more reliable; and this was the method employed in these experiments. Nicotine acted on nerve and on muscle, at first exciting and then depressing. The pure accelerator fibres were first stimulated, and in the fresh heart this acceleration was generally accompanied by increased tonus. Later the accelerators were depressed as shown by negative response to stimulation of the sympathetic, which prior to nicotine caused acceleration. The inhibitor mechanism was next excited, causing a slowing of the rate and cessation of beat with 0·2 per cent. solution, the heart remaining quiescent during one to three or four minutes. The purely augmentor fibres were excited early by nicotine, but this effect was best revealed after the stimulation of inhibitors had passed off. If the tone of the augmentors was increased by artificial stimulation before the drug, then the increase in force of the beat caused by this was very great. It had been shown by a simple device that the heart could perform more work in this phase, taking an augmented inflow comfortably and expelling it against increased resistance. Atropine did not counteract nicotine slowing. Atropine was said to paralyse the vagus endings in doses of 0·001 mg. or over. Amounts much greater than this were perfused for some minutes prior to nicotine perfusion, but without affecting the inhibiting action of the latter; therefore, it was probable that nicotine excited the post-ganglionic fibres of the vagus, just as it excited post-ganglionic accelerator fibres. A phenomenon of much interest observed frequently in the experiments was reversal of the heart beat by nicotine. The ordinarily subordinate mechanism of the ventricle was stimulated by the drug to predominance, so that the ventricle led the cycle. This might occur with or without cessation of the auricle beat as a preliminary, but the auricle-ventricle interval had been seen frequently to become shorter before reversal set in. It was also shown that a block could be temporarily broken down by nicotine, a 2–1 rhythm being converted to 1–1. Its action on the muscle connecting auricle to ventricle pointed rather to Englemann's view of a dromotropic delay in the impulse from above (lowered conductivity) than to the De Boer view of a prolonged refractory phase in the ventricle. Numerous graphic records illustrating the above points were shown.

Dr. F. W. LAMB gave an account of the various histological methods used in the study of fat globules in cells and discussed the modification of fatty compounds in their passage through the intestinal epithelium. He believed that all fatty bodies, with the exception of triolein, underwent an alteration or partial specialisation in the epithelium.

LONDON DERMATOLOGICAL SOCIETY.—The annual meeting of the above society was held at St. John's Hospital for Diseases of the Skin on June 19th, the President, Dr. W. Knowsley Sibley, being in the chair. The honorary secretary presented the annual report and said that the council were happy to record a successful year. The numbers had increased considerably; three new life fellows, 30 fellows, four members, and two associates had been elected during the present session. The officers elected for the ensuing year were Captain W. Griffith, R.A.M.C., President; Dr. Morgan Dockrell, honorary secretary; Dr. Knowsley Sibley, honorary treasurer. A clinical meeting followed.

Reviews and Notices of Books.

Obstetrics: Normal and Operative. By GEORGE PEARLA SHEARS, B.S., M.D., Professor of Obstetrics and Attending Obstetrician at the New York Polyclinic Medical School and Hospital. With 419 illustrations. London and Philadelphia: J. B. Lippincott Company. 1916. Pp. 745. Price 25*s.* net.

THE author has added this work to the already large number of text-books on the subject of Obstetrics, because he considers that most obstetric works contain too much irrelevant matter and too little about the practice of obstetrics. The book is based upon his experience in, and teaching at, the Cornell University Medical College and at the New York Polyclinic. With much of the author's teaching we are in complete agreement, but on some matters we hold different opinions in common with many British obstetricians, we feel sure. With the great importance of avoiding vaginal examinations and performing more frequent abdominal palpation we cordially agree. At the same time we think that in carrying out the latter manœuvre the advice to use the tips of the fingers and not the palms of the hands is quite wrong. The formation of the ring of Bandl, quite rightly according to English teaching, is attributed to excessive retraction of the uterus, but when the student is further told that the ring of Bandl is not present in tonic contraction of the uterus we entirely disagree. Dr. Shears appears to us to confuse the retraction ring and a contraction ring—two different conditions. The important clinical difference between secondary inertia of the uterus and tetanic contraction is not pointed out clearly. The teaching that the best method of treating an unreduced occipito-posterior presentation of the head may be to practise version, even when the head has passed the brim but is arrested in the pelvic cavity, or, failing this, the suggestion to rotate the head with the forceps rather than to carry out manual rotation, is contrary to the accepted practice in this country. The author, however, says that he has found rotation with the forceps easy and successful.

Dr. Shears maintains that clear and correct descriptions of the treatment of fœtal asphyxia are rare, and that some writers seem to have no positive opinions at all upon the subject. The description furnished in this book is not, however, by any means perfect; the fact that asphyxia pallida is really due mainly to shock, and that the chief danger is the heart failure which is present, is not stated—an important matter which in any description of this condition requires particular emphasis, since it forms the key to all successful methods of treating asphyxia pallida. In this section some very interesting details are given of the effect on the fœtus of oxygen inhalations by the mother, and the benefit to be derived from them is pointed out.

The book is in many ways a good one and should prove useful to the student. It is, however, somewhat spoilt by the slighting manner in which the author constantly refers to the writings of others. Many of his strictures are not deserved, and we can only conclude that he has not a very wide acquaintance with the best text-books of obstetrics in the English language, many of which are extremely practical as well as quite well written.

Commentaires de la Faculté de Médecine de l'Université de Paris (1395–1516). Publiés avec une Introduction et des Notes par le Dr. ERNEST WICKERSHEIMER, Bibliothécaire de l'Académie de Médecine. 4to. Paris: Imprimerie Nationale.

IN a large quarto volume of some 561 pages the librarian of the Académie de Médecine of Paris, Dr. Ernest Wickersheimer, has edited the "Commentaires de la Faculté de Médecine de l'Université de Paris" from the year 1395 to 1516. The Commentaires comprise 24 volumes in all and date from Nov. 6th, 1395, to November, 1786. Described in a few words, they constitute the administrative history of the Faculté de Médecine as recorded by successive deans. The origin of the faculty is not easy to trace, for though, according to the chronicler Guillaume le Breton, the art of healing and the care of the body were taught in Paris as early as the year 1210, *physici* or physicians are not

mentioned in documents until 1213, when, in an episcopal charge concerning the *licence* of the University of Paris, theologians, *décretistes*, artists, and *physici* are separately enumerated. In 1251 the University of Paris begins to employ the word *Medicina*.

In the fifteenth century, which is the period mainly covered by M. Wickersheimer's learned labours, medical education in the University is already being pursued with the help of certain books and by disputations. Every Bachelor is required to go through four courses, the first of which must be begun a fortnight after he has been received. A course is taken up with the study of a given book, such as the Aphorisms of Hippocrates, the Viaticum or Book VII. of Isaac Judæus, who died in the tenth century, Gilles de Corbeille on the Urine, the works of Rhases, Avicenna, Galen. It is curious to note that though the study and criticism of books were thus insisted on, there were only some 38 works on medicine and surgery in the library of the Faculty in the years between 1395 and 1516. These were manuscripts on parchment, some of them illuminated, and probably of value, for one was in pawn in 1395 *chez Guillaume Boucher*. Thirty-eight volumes could only necessarily go round among a very small circle of readers. Disputations were carried on by the Masters in Medicine and respectfully and quietly listened to by the Bachelors. One of the subjects was "Utrum rerum naturalium, non naturalium et preter naturalium, cognitio medico sit necessaria?" These disputations were called *Quolibets*, not because they were on any subject, but because the answer was Yes or No. Theses were written then as now, and a candidate for the licence might choose his examiner, who was probably his own teacher, but he had two assessors, and the transaction or bargain had to be above board—"sine fraude et deceptione."

The Medical Faculty comprised four grades—students, Bachelors, Licentiates, and Masters or Doctors. Students were not as young as most of the University men of that age, for they were required to pass four years in the study of medicine before obtaining the baccalaureatship unless they had previously graduated in arts, when the course was three years. In 1426 Pope Martin V. decreed that the medical licence could only be obtained by graduates in arts. A high standard of literary culture was thus ensured, though the science of the time had little value.

M. Wickersheimer's monumental work has been published under the auspices of the Ministry of Public Instruction and Fine Arts. It is one of the "Collection de Documents Inédits sur l'Histoire de France." The librarian of the Académie de Médecine is to be congratulated on his erudition. He is probably—to judge by his name—one of that long line of brilliant Alsatians who have adorned French science since the days of Adolphe Wurtz and Gerhardt. We understand that he is now at the front helping to win back those lost provinces that have contributed so greatly to the civilisation of France.

Reports of Inquiries and Appeals under the National Health Insurance (Medical Benefit) Regulations (England), 1915. Vol. I. London: H.M. Stationery Office. 1917. Pp. 163. Price 9*d*.

THE Insurance Commissioners have initiated a series of reports of the inquiries instituted by them under the medical benefit regulations, and these reports should prove very useful in connexion with the various questions which, in the first instance, are the subject of investigation by Insurance Committees and their subcommittees. The decisions which the Commissioners are called upon to give affect a wider and more varied range of subjects than might at first be supposed. The development and enunciation of the principles to be applied in cases where medical men, druggists, insured persons, and Insurance Committees find themselves at variance should tend to diminish the number of disputes arising as well as to the speedy and satisfactory disposal of them.

A considerable proportion of the cases referred to the Commissioners naturally bring under their notice comparatively simple questions with regard to which, when the facts have been established, there can be little doubt as to the course to be pursued. Among cases of this kind may be placed many of those in which a medical practitioner's removal from the panel is sought for upon the representation of an Insurance Committee. Such cases are quite rare when the large number of practitioners upon the panels, and the varying circumstances in which their lives have been spent, are taken into consideration. When a medical man is proved upon more than one occasion to have been in a state of intoxication when visiting his patients (Part I., Case VII., p. 13; Case XIII., p. 24), to have habitually left patients to be treated by an unqualified assistant (Part I., Case XVI., p. 34), or to have been the putative father of the children of a patient (Part I., Case X., p. 19), little remains to be said. His retention upon the panel would neither be desirable in the interests of his profession nor of his patients, and his case is as simple as those affecting druggists, in which fraudulent overcharges are proved to have been made, supported by proof of alterations deliberately made by the druggist in the doctor's prescriptions (Part II., Case V., p. 64; Case VI., p. 67; Case VII., p. 69). Other subjects are of greater complexity. Among these may be placed questions of proposed surcharge on the ground of alleged extravagant prescribing. Twelve appeals relating to this very important matter are included, and the fact that the decisions in this class of case involve questions of principle, and should serve as precedents, is emphasised by the use of headnotes summarising the conclusions arrived at. Thus we read (Part III., Case IV., p. 80) that—

> Statistical evidence does not suffice, standing alone, to justify the inference of extravagance, but in conjunction with evidence derived from the character of the prescriptions themselves, and in the absence of satisfactory explanation by the doctor, it may assist both in establishing the fact of extravagance and in enabling a reasonable estimate to be made of the additional cost thereby caused to the Drug Fund.

Naturally it is in cases where principles have to be sought for, and by which precedents of importance may be established, that differences of opinion may arise as to the correctness of the decision arrived at. In one such instance (Part IV., Case II., p. 123) a panel doctor was requested by a patient's mother to obtain a second opinion, a step which he considered unnecessary, and which in the end only served to confirm his diagnosis and treatment. On the ground that the consultation was unnecessary, and that in attending it he was acting on behalf of the patient's mother, the panel practitioner charged a fee. The Insurance Committee decided that the charge was a breach of the doctor's agreement, and the Commissioners rejected his appeal, holding "that as the appellant had, in fact, attended the consultation his action was for the general benefit of the patient, and in view of the mother's anxiety the consultation was not unnecessary." The question of fees for attending consultations in the circumstances indicated is likely to be raised more frequently when the provision of the opportunity for consultations arouses more frequent demand for them among insured persons, and no doubt the difficulty will then be more fully provided against. There is certainly an element of hardship in a case which compels a medical man to attend gratis a consultation considered by him unnecessary, with the alternative of absenting himself when another medical man seeks information as to the patient's condition and treatment.

The general impression conveyed by a perusal of the Commissioners' decisions, and of the principles upon which they are based, is one of an industrious endeavour to sift the cases before them with thoroughness and to arrive at just conclusions. This cannot always have been easy, for the questions raised have had many and varied aspects. The difficulties have arisen out of the administration of a complicated system of a novel character, necessitating the breaking of fresh ground and the creating rather than the following of precedents. Whatever view, however, may be held as to the merits of a particular decision or decisions, there can be no question as to the desirability of assembling and publishing such decisions in the convenient form adopted.

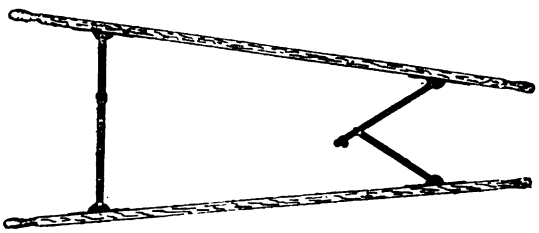
JOURNALS.

La Chirurgia degli Organi di Movimento.—All concerned in its production are to be congratulated on the first number of this new Italian surgical periodical. It is published by L. Capelli, Bologna, and the agents for this country are Messrs. Williams and Norgate. The first article, "La Mobilizzazione Chirurgica delle Anchilosi del Ginocchio," is from the pen of the editor, Dr. V. Putti, professor of orthopædics in the University of Bologna. Dr. Putti discusses very fully the operative treatment of bony ankylosis of the

knee by the latest methods, describes in detail those adopted by himself, and gives histories of cases in illustration. One of the cases cited is of extraordinary interest. The patient, a field labourer, was operated on for bony ankylosis of the knee in 1911. The method of operation adopted was that described by Dr. Putti in the *Archivio di Ortopedia* in 1913.[1] The ankylosis was broken down and the joint resected. The condyles of the femur were covered with pads of the fascia lata dissected from the patient's thigh, in the hope that a fresh synostosis would thereby be prevented, and that the aponeurotic tissue might take a useful part in the formation of a new joint. The result as regards mobility was not satisfactory, and three years after the first operation the patient requested further surgical intervention. Dr. Putti performed a second resection and found a condition of the joint which showed that the imperfect result of the first operation was due to its too conservative character and in particular to the non-removal of the crucial ligaments and the cartilage covering the articular surface of the tibia. The point of chief interest, however, is the condition of the covering of fascia lata which had been applied to the condyles of the femur three years before. This was found living and firmly adherent to the bone. It was removed in the course of the fresh resection and submitted to a histologist for examination. Under the microscope, while its original character, of an aponeurosis, was plain, it was seen to have undergone a considerable metamorphosis towards cartilage. The very full and interesting report of the histologist concludes as follows: "In conclusion, the fascia interposed in this patient between two osseous articular surfaces is living and is undergoing a cartilaginous metamorphosis which tends to reproduce the normal morphological conditions of the joint even in detail." Dr. Putti gives a very full and clear account of the technique he follows in his resections, and accompanies it with a series of admirable illustrations. Clinical histories are given of six cases of resection after his method. In the fully successful cases the mobility, strength, and general usefulness of the new joint are quite extraordinarily good.—The three remaining articles in the present number contain much that is of interest to orthopædists. Dr. Vaughetti writes on the present condition of prosthetic surgery ("Progressi Actuali della Plastica Cinematica"), while Dr. Delitala discusses the normal and pathological anatomy of the skeleton of the foot, with special reference to wounds, and Dr. Serra contributes a histological study of transplantation of bone in the human subject. A word of praise must finally be given to the typography of this number and to the excellence of the numerous illustrations.

The Military Surgeon. Washington, D.C. May, 1917.—The number opens with an appreciation of the Carrel-Dakin method of wound sterilisation, "the most valuable advance in the treatment of infected wounds" learned in this war, by Colonel William H. Arthur, Medical Corps, U.S. Army, Commandant of the Army Medical School. He notes the essentials to be, first, thorough opening and drainage, cleaning of the wound from foreign bodies and dead tissue, the complete arrest of hæmorrhage; then the continuous bathing of the wound, every nook and cranny of it, with an efficient, non-irritating bactericide. He concludes that the chemical skill of Dakin assisted the mechanical dexterity of Carrel.—Colonel Louis La Garde, Medical Corps, U.S. Army, retired, tells the civil profession they should join the Army now to help, and not delay till they can get the particular sort of work they prefer. He tells how Dr. Nicholas Senn, of Chicago, designated in 1898 as the chief operating surgeon of all the armies in the field, came to Cuba after the fighting was over and the wounded had been sent home, but, having no operations to do, was content to take 70 Cuban refugees and clean up a burned town to make a site for a hospital. That was the work his country needed done. That was the work Senn was ready to do.—Surgeon (Fleet-Surgeon that is) W. M. Garton, U.S. Navy, describes how the food of the men of the fleet is inspected in a United States dockyard. The Fleet-Surgeon (Principal Medical Officer of the Fleet) is responsible for the quality of the food, assisted by the Fleet pharmacist. He lays great stress on regular hours for supply to give time and light for inspection. Bread, milk, and apparently meat are inspected daily, clams, oysters, and yeast on Fridays, fowl and cake on Saturdays or the day before holidays, and ice-cream on Sundays. We hope the fowl, cake, and ice-cream, which appear to furnish forth the Sunday dinner of the U.S. Navy, may be found on this side not to fall below the Transatlantic standard.—First Lieutenant W. E. Fitch, Medical Reserve Corps, U.S. Army, discusses rations for boys in military training camps. He takes 4000 as the number of calories required by a man at active work, and, on the authority of Du Bois (Russell Sage Foundation), demands for boys 25 per cent. more, 5000 calories, to satisfy the ravenous appetites which result from the energy expended in exercise and growth. This food he supplies particularly in whole-wheat bread, eggs, meat, fresh vegetables and fruits, observing that long-cooked food, tinned meat, condensed milk, &c., have lost their vitamines, while he puts white patent roller process flour on the same level as polished rice. He gives his boys in camp meat at every meal, yet only about half a pound a day, but the calories he gets mainly out of cereals, potatoes, beans, and, of course, in America, pie.

Archives de Médecine et de Pharmacie Militaires. Tome LXVII., No. 1. January, 1917. Paris: L. Fournier.—In an article on Fractures of Bones, and especially Displacements of the Fragments, caused by Firearms, by Ed. Delorme, Médecin Inspecteur Général, Membre de l'Académie de Médecine, profusely illustrated by sketches taken from radiographic plates, the author states that the experiments concerning the result of gunshot wounds made on the cadaver by himself and Captain Jaricot in 1881 had enabled him to classify the principal types of fractures of the diaphyses and epiphyses of the bones. It appears that such a study gives often more precise results as to the lines of fissure than radiography owing to the super-position on the plate of both surfaces of the bone. These anatomical studies, supplemented by the examination of thousands of wounded men and of radiographic plates, show that: 1. The German S bullet acts similarly to its predecessors in causing the various lesions of the bones. 2. That shrapnel bullets give simpler types owing to their lower velocity. 3. That splinters from shells, grenades, &c., give types similar to those of shrapnel bullets with a few differences, such as (*a*) fractures without solution of continuity of the bone, which may or may not be comminuted; (*b*) fractures of simple types, with solution of continuity; (*c*) fractures of a complex type, more or less comminuted, with solution of continuity. He enunciates the two following laws: (1) A fracture of the diaphysis is less extensive longitudinally as the velocity of the bullet increases; but (2) as a rule, the fracture is more extensively comminuted as the velocity of the projectile is augmented. Inspector-General Delorme points out that trench warfare, with its shorter range, provides examples of the latter type of fracture more frequently than did fighting in the open during the earlier days of the war, and then deals in detail with all the fractures of the bones of the upper extremity, commencing with those of the fingers and finishing with the bones of the shoulder-joint. All these lesions conform to the following category: (1) abrasions or contusions with or without fracture by the contact of the bullet or splinter; (2) deep pitting of the bone; (3) grooving or guttering of the bone; (4) perforation, with the formation of large splinters, sometimes wedge-shaped, or the bone may be extensively comminuted and reduced to small fragments held together by the periosteum. The various types of callus are mentioned, and especially callus formed after gunshot wounds of the shoulder, where it is often extensive owing to the many centres from which ossification may proceed. Displacements of the bones are described, such as those of the forearm, arm, and shoulder, and M. Delorme insists upon the necessity of great care being taken to correct any vicious position. He has seen marvellous recoveries of joints when these have been implicated in serious lesions owing to the great care taken in rectifying faulty positions and the use of suitable appliances until healing has taken place. The author is not favourably inclined to primary excisions of joints unless the lesion is limited to the immediate neighbourhood of the joint and below the epiphyseal line, for if the diaphysis be implicated the surgeon may remove too much bone in his endeavour to go beyond all damaged portions of bones. Pseudo-arthrosis is found to occur most frequently after fracture of the radius alone, or ulna alone.



[1] L'interposizione di lembi aponeurotici liberi nella mobilizzazione chirurgica delle anchilosi e delle rigidita articolari.

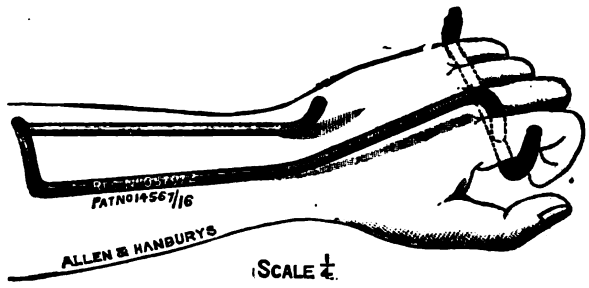
Journal of the East Africa and Uganda Natural History Society. March, 1917. Longmans, Green, and Co. Price 5*s*. 4*d*.—The relation of climate to health gives particular interest to the several articles which have appeared from time to time in this journal on desiccation or the gradual drying up of rivers and lakes in Africa. In the current issue Mr. R. L. Harger gives a summary of observations on the subject made by older travellers—namely, Mr. G. W. Stow (*circa* 1843) and Livingstone—and records his own observations made between the years 1894 and 1906. A review of the facts stated show that the inland plateau of Africa up to the Equator can be divided roughly into three lateral zones: (1) From about the latitude of the Orange River to the Zambesi, where vast rivers and lakes have disappeared, leaving mere remnants, such as Lake Ngami; (2) from the Zambesi to the latitude of Lake Mweru, where large river systems and huge lake areas are in process of being drained; and (3) the equatorial belt, excluding Tanganyika, where the climate, rainfall, and vegetation are such, together with abundance of water, as to warrant the supposition that drainage and desiccation have not yet commenced.—A short note on Albinism in East Africa, by Mr. S. L. Hinde, expresses the opinion that possibly a larger percentage of albinos are born to negro parents in tropical Africa than is born to European parents in Europe. These children are seldom seen by Europeans, as many tribes destroy them at, or soon after, birth, and those that are allowed to survive are difficult to rear. Under the title of "A Rare Forest Francolin," Dr. V. G. L. van Someren, the honorary secretary of the society, describes the *Francolinus lathami schubotzi*, and a beautiful coloured plate shows the male and female of these birds.

New Inventions.

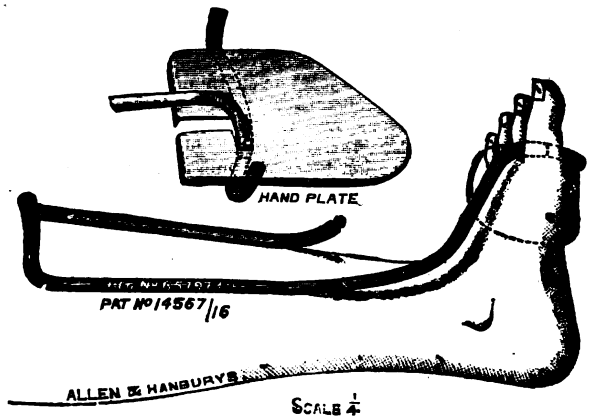
A BED-CARRIER.

AT this hospital last summer on fine days patients were carried out of doors in their beds. This necessitated carrying the bed and patient 100 yards and up and down a broad flight of ten steps. Four strong men were required to carry a single bed, and for four men it was a considerable exertion. From unequal lifting it was a strain on the bedstead. The bedsteads are light, of the ordinary hospital pattern, measuring 6 ft. 4 in. by 3 ft. 3 in.

The hospital carpenter made a bed-carrier by the use of which two men could do the work of four with less exertion. It is a simple contrivance. No claim is made for originality, but in view of its convenience its description is made known.



It consists of two stretcher poles, each measuring 104 × 1¼ × 2¼ inches, their ends fashioned to form handles (see figure). The poles are joined at a distance from either end, corresponding with the head and foot of the bed, by a jointed flat iron bar, one-half of which overlaps the other at the central join. The longer half is turned over at its end to grip its fellow, thus preventing over-extension. Each half has a hinged attachment to the pole to allow of the two poles being collapsed together. The carrier in use, when the jointed bars are extended, lies under the bed frame. Four buttresses on the poles rest hard up against each leg of the bedstead to prevent the bed slipping when carried up an incline. The two jointed bars when fully extended form a rigid iron bar which prevents collapse of the poles when a man at each end lifts the pole handles to carry.



A. GEOFFREY EVANS,
R.N. Hospital, Mount Stuart. Temporary Surgeon, R.N.

WRIST- AND FOOT-DROP SPLINTS.

THE following is a description of two splints which have been found very useful in the prevention and treatment of "wrist-drop" and "foot-drop" in cases of injury to muscle and nerve. They have been designed by Miss Wharton, one of the dressers in the Hôpital Temporaire d'Arc-en-Barrois (Haute-Marne).

The splint is made of iron wire, strong enough to support the limb but capable of forcible bending to fit it to the peculiarities of individual cases. It consists, as will be seen in the illustrations, of a support on the palmar or plantar aspect of the limb, attached to a wire, which, passing between the index and middle fingers or great and second toe, crosses the dorsal surface of the hand or foot without

actually touching it, and continuing up the forearm or leg is fixed in the manner shown in the drawing, by a few turns of bandage. In the foot-splint the support is made in sheet metal, while in the hand it consists only of a single wire with a detachable sheet-metal finger support. In "*foot-drop*" the advantages of the splint as compared with the ordinary back splint, for example, are: Its simplicity, lightness (the patient is perfectly free to adopt any change of position he cares to without suffering the restraining influence of the heavy posterior splint), ease of appliance—e.g., a few turns of a bandage on the leg only, which renders it capable of appliance in spite of wounds, adaptability to cases, absence of any risk of pressure sore in the heel region and possibility of walking on crutches while wearing the splint. In "*wrist-drop*" its light weight is again the most commendable attribute, and the fact that the splint is fixed by a bandage on the forearm only, leaving the hand free and enabling the fingers to be used while the wrist is supported in a position of dorsiflexion to the amount desired for the case. If it is thought desirable to keep the fingers in an extended position the detachable finger support is used. If it were objected that there were pressure on the affected muscles, which is almost inconceivable in such a light apparatus, a modified form in which the arm-piece is applied to the anterior surface of the forearm is made. These splints are in constant use in the Arc-en-Barrois Hospital and have been found very effective in the prevention and treatment of foot- and wrist-drop and after nerve sutures. They have also been commended and adopted by certain French surgeons of other hospitals.

The splints are made and supplied by Messrs. Allen and Hanburys, Limited, 48, Wigmore-street, London, W., and catalogued by them as the "Wharton's Splint."

A. F. SINCLAIR,
Surgeon, Hôpital Temporaire, Arc-en-Barrois.

THE LANCET.

LONDON: SATURDAY, JUNE 30, 1917.

Mesopotamia: Then and Now.

THE Report of the Commission appointed to inquire into the Operations of War in Mesopotamia was presented to Parliament on Tuesday last, and constitutes one of the most tragic confessions of official muddle known to our history. The Report strikes us as moderate although so outspoken, for indeed the political and military miscalculations which led to the first advance on Bagdad, the siege of Kut, and the surrender of more than a division of first-class troops, with over 20,000 casualties, are now seen to have been gross. Coming to the breakdown in the medical arrangements; there is published with the Report a complete endorsement of the findings of the Vincent-Bingley Commission which went out to Mesopotamia early last year to review the medical arrangements; and from these findings, which form Appendix I., as well as from the whole Report it becomes clear that at the beginning of the campaign the provision for the sick and wounded was inadequate. After the battle of Ctesiphon and during the Kut relief operations the medical arrangements entirely broke down, and Surgeon-General HATHAWAY, the Principal Medical Officer in Mesopotamia, Surgeon-General BABTIE, the Director of Medical Services in India up to June, 1915, and his successor, Surgeon-General MACNEECE, are all found to blame in varying measure, despite the splendid work, acknowledged by the Commission, of the executive and regimental medical officers. No doubt each of the high officials desired to do his best, and no doubt each of them can show that he advanced claims for attention to the needs of his department which were not attended to by military or civil authorities, but it emerges from the Report that they did not recognise the seriousness of the situation. Lieutenant-Colonel R. M. CARTER, I.M.S., the first man to report truthfully to his superiors on what was really happening, was snubbed and even threatened. This makes a sorry tale.

An officer in the Royal Army Medical Corps who uses the pseudonym "MARTIN SWAYNE," has just published a book which deserves to be widely read as a sequel to the Report. The book is entitled "In Mesopotamia," and in it he tells us of a white doorway in a yellow wall which local tradition regards as the gate of the Garden of Eden. No garden is there now, but the gate is at the junction of the Euphrates and the Tigris. The two gigantic rivers rush through stretches of land so barren that no green thing was available for our troops on the march up from the Gulf. Tinned fruits and vegetables, which should have come, failed, and the men marched day after day drawing on the mineral salts stored in their bodies, and finally upon their own lecithin, until beri-beri set in and they were invalided back again to India whence they had come. Instead of a succession of fruits in the garden for the use of man, man became himself the soil on which flourished one after another a virulent series of bacterial crops. Plague followed cholera, and malaria found a seed-bed prepared by the enteric fevers and dysentery. The water of the rivers which once flowed through the garden, making possible the leafy shade in which the LORD GOD walked in the cool of the evening, was but the vehicle of deadly germs. Under such conditions it is no surprise that the sick and wounded were "lean, gaunt, haggard skeletons, hollow-eyed, with rivulets of perspiration furrowing the dirt of their faces." The vessels in which they came down stream from the fighting above consisted of ordinary river-boats with a big barge lashed on each side, on the deck of which the men lay closely packed under a single thickness of canvas awning. With the rising humidity of evening heat-stroke was often added to the other terrors. Such were the conditions for the sick and wounded in Mesopotamia in the first half of the war, which is now completing its third year, and such they would have remained if it had not been for the tardy but strenuous application of the principles of hygiene, principles sufficiently well known before but not applied.

Whether the insanitation was due to the parsimony or the ignorance of authorities, hard to convince of the certainty of disaster entailed by the lack of hygiene, is an idle speculation. The Garden of Eden is being restored. Irrigation on a small scale is already producing more than enough vegetables to supply the needs of troops and cattle. Up and down the whole length of the river water-purifying installations have been erected, each complete in itself and providing an abundant supply of pure water for so many units. Traffic on the river for the sick and wounded is no longer a protracted torture. A fleet of hospital ships, some of shallow enough draught to ply right up into the Armenian mountains, provide all the conditions for safe and rapid convalescence. One of these river boats, which we were able to describe last week from a personal inspection, is a model of applied medicine, each several requirement having received its appropriate attention. The enormous expenditure of thought and money in the directions which we have indicated has had already obvious justification, but to the clear-sighted medical administrator the prospect of their permanence adds vastly to the interest of his work. Not only for attack and defence are these conditions essential; they are also the conditions of peaceful development. The same irrigation, multiplied a thousand times, can turn Mesopotamia once more into a fertile plain, with an annual output of cotton and of corn worth hundreds of millions of pounds. Hospital ships, no longer required for maimed and broken men, can remain as the beginning of regular means of healthy river transit. The installations of pure water will be required as the nucleus of a vast permanent source. If the new Garden of Eden is better than the old, it may be because the medical profession has eaten to some purpose of the fruit of the tree, and turned to advantage its knowledge of good and evil, untrammeled by prejudice and vested interest.

The Day's Work and the Cost.

THE Cavendish lecture delivered before the West London Medico-Chirurgical Society by Captain ANDREW MACPHAIL, of the Canadian Army Medical Corps, Professor of the History of Medicine in McGill University, Montreal, will be found printed in full on other pages. Captain MACPHAIL has drawn a vivid picture with a sincere and accomplished pen of the work of the medical men at the front, choosing, as his example of "A Day's Work," the advance of the Canadian Corps at Vimy Ridge on Easter Monday, an advance which was carried out with brilliant success, the result of organised work by day and night through weeks and months of methodical preparation. On that day the Canadian Army Medical Corps played a part carefully rehearsed beforehand with the other actors in the great drama, and showed how ably men trained thoroughly and methodically in the hospitals of their home country in time of peace can adapt themselves, organise their methods, and apply their acquired knowledge and skill as integral parts of a vast army face to face with every death-dealing device employed by a resourceful enemy.

This is the principal lesson taught by Captain MACPHAIL in his address, but learned and eloquent man that he is, he has seized upon an unrivalled opportunity to suggest for our consideration many other matters of the first importance. We realise from his story that the work of a day to be effective, whether for a soldier or a surgeon, must be the result of training and preparation, and that even the initiative and resource which superficial observers may ascribe to natural ingenuity, stimulated by emergency in at least an equal degree, should owe origin to education and cultivated habits of forethought—habits which seem to have been considerably wanting in those responsible for the initiation of the Mesopotamia campaign. Captain MACPHAIL describes how on one occasion at the Western front an apparently ample supply of blankets for an expected flow of wounded into a dressing station was suddenly rendered insufficient by bitter wind and driving snow. Within an hour, however, 600 additional blankets were assembled and transported to where they were needed. Captain MACPHAIL adds that how this was done "does not matter," but we are free to conjecture that someone knew that something of the kind might occur, and had kept ready at the back of his mind details of how and where fresh blankets might be got, if the necessity for them should become urgent. Resource and readiness for emergency, as rendered possible by the medical man's early training, are not, however, only called for by such emergencies as a snowstorm. One of the side lessons taught in the lecture referred to is the fact that, whatever red tape may necessarily associate itself with all military organisation, no unalterable routine can regulate the arrangements to be made before a battle for the reception of the wounded, any more than the treatment of individual cases when they arrive can be laid down beforehand. Captain MACPHAIL says, speaking of the preparations made from early in February onwards for the battle of Easter Monday, "No one system will suit all engagements, and the system must be devised in case of defeat as well as in victory"; and he adds later, "I cannot insist too strongly that medical arrangements must be devised anew for each action; they vary with the plan of battle and must be modified as the battle proceeds." Throughout the war, in the exhibition of resource based upon training and knowledge, Captain MACPHAIL shows us, the Royal Army Medical Corps, with its ranks filled and refilled by men of varying degrees of scientific attainment, torn from the various branches of civil practice, has won high distinction. "It has yielded an army without sickness." The words are those of Captain MACPHAIL, who has never seen a case of typhoid at the front; and he speaks of London as "a place where men contract venereal disease," whereas our army, fighting and resting alternately in France under medical supervision, is free from it—the first army that ever could be so described in such circumstances. It is with little wonder, then, that we learn from the utterance of Captain MACPHAIL that "by the miracle it has performed of keeping the Army fit the consideration accorded to the service is unbounded."

But if the medical profession has gained distinction for itself by the manner in which it has accomplished its work in the war, most assuredly the cost of its success has been heavy. A recent Ministerial answer in the House of Commons told us that, excluding the figures which are not obtainable as to medical officers from oversea, the losses of the medical profession in Regular and Territorial officers have amounted to 137 killed in action, 58 dead from wounds, and 62 from disease, 707 having been wounded. How many may yet be added to the total of those who have lost their lives it would be rash to estimate even roughly, and none can reckon how many of those described as wounded have been permanently incapacitated from the pursuit of their professional careers. Those who have fallen have paid in full the price which war exacts from the patriot. They include among their number young men of high capacity whom a future generation might have seen taking their places as eminent figures in the world of surgery and medicine. They include many who would have served their fellow-men usefully and honourably, if without fame, and some others for whom the future might only have had in store worldly disappointment. All these, however, are now equal in the fact that they have died upholding on the battle-front the traditions of the profession of medicine which never before in its history has had so great an opportunity for showing its zeal in the cause of country and fellow citizen, and which has so manfully seized the chance. Let us see that in death they are not forgotten either by their colleagues or their country. When honourable mention is made of the achievements of medical and surgical science in the great war—and the records of that work will surely constitute a monument more enduring than brass—let the names of those be recalled who fell while tending the wounded and

the dying within range of the guns. The debt to them is one which in some measure can be repaid, for in not a few instances they will have left dependants whose mourning for their loss will be rendered more bitter by straitened circumstances. These will need our aid for many years to come, and a generation not yet grown to manhood and womanhood will have to extend a helping hand to some of them, and assist them to win independence for themselves. Meanwhile, as Captain MACPHAIL says, the end is not yet, nor is it even in sight, and the medical profession will continue to face the day's work from day to day, not reckoning too closely the cost in toil and money loss, but remembering those who have paid their share in the sacrifice of their lives.

Man Power and Medical Re-examination.

IN the House of Commons sitting as a Committee on the Army Estimates, Mr. PRINGLE, the Liberal Member for North-West Lanarkshire, moved last week a reduction in the vote for the War Office of £100 in order to call attention to what he termed "the scandal in connexion with the medical re-examination of discharged and rejected men." Mr. PRINGLE spoke at length and gave numerous examples which he considered formed a proof that, to quote his picturesque language, "the halt, the lame, the blind, the mute, the mad, and even the dead" had been summoned before the examining boards set up under the Military Service (Review of Exceptions) Act. Mr. PRINGLE was supported by Sir GODFREY BARING, the Member for Barnstaple especially bringing to the attention of the House examples of what he described as the insolent attitude of the military medical boards towards those submitting themselves for re-examination. The Under Secretary for War made a carefully considered reply, in which he admitted that under the Act whose working was being criticised some 950,000 men might be called upon for medical examination in the hope only of obtaining 120,000 recruits, half of whom, it was anticipated, would be placed in Class A. These official figures make it perfectly certain that the working of the Act was bound to be intensely unpopular, and that it would necessarily be attended with many cases of disappointment and hardship; but Mr. MACPHERSON was able to show that much of the criticism of his department was based upon an inability to comprehend the composition of the Army of to-day, and to appreciate the fact that it required one and a half men behind the lines to keep one man in the trenches, so that the majority of men who were called up would be required rather in work similar to civil employ than actually for fighting. If the India Office and the Government of India had had sufficient imagination to see this much in 1915, the disasters of the Mesopotamia campaign might have been avoided. Mr. MACPHERSON also made it clear that men who had served abroad and had been discharged from the Army for sickness or wounds, and who now come in under the working of the new Act, will be finally discharged.

Mr. ASQUITH adduced from the result of the appeals made to the County of London Tribunal during nine months that the work of medical boards displayed too large a margin of error, and thus gave authority to that aspect of the debate which reflected more upon the medical profession as recruiting officers than upon the administration of the War Office. In fact, the medical profession were placed by the debate in the unpleasant position, and not for the first time, of being, on the one hand, the objects of criticism, and, on the other, the bulwark behind which those criticised were sheltering themselves. We do not for a moment suggest that no errors in diagnosis have been made by military medical boards, but in spite of the evidence of the post-bags of Members of Parliament, we make bold to say that the margin of error has not been great, while it has grown steadily less. And has there been no reason entirely outside the discretion of the medical profession why certain of these errors have occurred? From all over the country, from all sorts of speakers, and in journals of every political and social complexion we have learnt that a large number of men, who would have been adjudged first-class fighting material, secured early exemption from service in the Army, leaving the medical boards to exercise their judgment upon a population which was thus lowered in its physical standard. Any percentage of error which has occurred must certainly have been increased by this factor. Again, certain of the cases which have given rise to the most distinct feelings of injury among those who have undergone re-examination have been due to the raising of their class as a recruit. But the system of classification had no medical origin. It was devised for military convenience, and recruiting medical officers have to exercise their judgment as best they can in conforming with its pattern. This is a point which the critics of the medical profession might once and for all be asked to remember.

The debate in the House of Commons on the Military Service (Review of Exceptions) Act was obviously political in its bearing. We are only concerned to place before our readers the medical aspects of the situation. The Act was considered necessary by the Government because there was an undoubted leakage which, in the interests of the country, ought to be stopped. It was bound to be an intensely unpopular measure, and every medical man knew that it would lead to many hard cases and much difficult and delicate exercise of judgment and diagnosis. In these circumstances the military medical boards appear to us to have discharged their painful and difficult duties with care and conscientiousness. We are perfectly aware that there must have been errors, but the errors, like the many cruelly hard cases, were produced by the provisions of the Act and not by the slackness or ignorance of the medical profession. Those who have criticised the medical profession most strictly are the least likely to possess accurate statistical information as to the percentage of mistakes which have been detected. A Parliamentary Committee has been appointed to examine the working of the Act.

Annotations.

"Ne quid nimis."

PERTUSSIS VACCINE.

THE employment of a vaccine in the treatment of whooping-cough is still on its trial and a large amount of work on the subject has recently been done at the whooping-cough clinic of the New York Department of Health. The vaccine has been freely supplied by the Department to practitioners in New York, and in a recent number of the *Journal of the American Medical Association* Dr. Paul Luttinger analyses the reports of 250 physicians who had used the vaccine. The clinical material was the average dispensary child on the East Side of the city. 952 cases treated with vaccine were compared with 149 similar cases treated with drugs; in the former the average duration of the paroxysmal stage was 37 days, in the latter over 50 days. The second week of the paroxysmal stage seemed to be the most favourable for vaccine treatment; earlier than this the vaccine sometimes did harm, while in the later weeks it was simply inert. Used as a prophylactic in patients exposed to infection, 94 per cent. escaped. Luttinger concludes that when the proper vaccine is given according to the method of the Health Department the disease is materially reduced in duration and severity, and that the results obtained warrant the routine administration of pertussis vaccine for both curative and prophylactic purposes. In the same number of the *Journal of the American Medical Association*, however, von Sholly, Blum, and Smith report a series of cases treated for whooping-cough by means of vaccines prepared from the influenza bacillus and from the whooping-cough bacillus and by a sham vaccine consisting of milk and water. They found that the results obtained by the non-specific influenza vaccine differed little from those which followed the use of the specific whooping-cough vaccine, and that the shortest cases were the non-vaccinated controls. None of the individuals inoculated with either vaccine for prophylactic purposes contracted the disease. These observers justly emphasise the great difficulty of estimating the value of any method of treatment in an illness as uncertain in its duration and irregular in its course as whooping-cough, especially when the patients are merely attending a clinic and living in their own homes, as was the case both with the series reported by Luttinger and their own. Their care in elaborating controls suggests that they feared the mothers of the patients might be, as it were, hypnotised by the new method of treatment into giving unduly favourable reports as to the severity and duration of the paroxysms. It is very much to be hoped that experiments with vaccine will be carried out on an even larger scale, and especially that its prophylactic effects will be very thoroughly tested. Infantile vaccination against whooping-cough, if effective, would save a very large number of lives even if the immunity conferred was of comparatively short duration. It is unfortunate that so little has been published on the subject in this country, and that the trials of vaccine which have certainly been made have not been reported. On the whole, results appear to have been negative, and it is possible that this may be explained by the extraordinary difference in the dosage of the vaccines supplied by firms in this country from that recommended by Luttinger. The vaccines here are sent out in doses of 5 and 10 million organisms, whereas 500 million to 10 billion were employed in New York. Admitting the great differences of opinion regarding vaccine dosage, there still seems remarkable discrepancy. The most striking observation made by Luttinger is that the presence of subconjunctival hæmorrhages in prophylactic cases which were protected by the vaccine seems to point to a specific immunising action against the paroxysms, and to the fallacy of the hitherto accepted theory that these hæmorrhages are due to the violence of the cough.

PARALYSIS OF THE RECURRENT LARYNGEAL NERVE BY BULLET WOUND.

A UNIQUE case of traumatic lesion limited to the left recurrent laryngeal nerve, without any injury to vessels, other nerves, or vital organs, has been published recently by Dr. U. Samaja, one of the military staff of the De Amicis Hospital at Bologna (*Gazzetta degli Ospedali e delle Cliniche*, No. 8). During an attack the patient received a shrapnel bullet wound in the left clavicular region; there was but little hæmorrhage and no hæmoptysis, although he was suffering from cough at the time. The wound of entrance was behind the clavicle in the supraclavicular fossa, 2 centimetres from the sterno-clavicular articulation. The bullet could be felt immediately below the second left rib about 1½ cm. from the sternal margin. The distance between the wound and the bullet was 10 cm. and its direction from behind forwards and from left to right. The skin between these two points was absolutely normal. A radiogram showed the existence of a fracture at the sternal end of the left clavicle and swelling of the sterno-clavicular joint. The apex of the left lung was more opaque than that of the right, pointing in all probability to a peri-pulmonary lesion. Persistent vocal alteration, which supervened immediately after the patient was wounded, was shown by laryngoscopy to be due to paralysis of the left recurrent laryngeal nerve, the left vocal cord being in a position intermediate between that of phonation and respiration, and remaining stationary during phonation. Thus the projectile, either directly or from hæmorrhage, of which the peri-pulmonary opacity was the residuum, had injured the left recurrent nerve and caused the vocal paralysis without damaging the lung itself, the subclavian vessels, or the phrenic and sympathetic nerves.

THE METROPOLITAN HOSPITAL SUNDAY FUND AND PAROCHIAL ORGANISATION.

THE claims of the Metropolitan Hospital Sunday Fund are brought forward with emphasis in the last issue of the *Hospital*. The editor lays stress upon the advantage which has already been derived in some instances from the organisation of hospital committees in individual parishes, which charge themselves with the duty of increasing the contributions of those who give to the Fund, and particularly of insuring that those who do not usually go to church on Sundays shall not forget it. It has frequently been urged in THE LANCET that those who do not attend Divine worship should contribute no less than those who do so, and that the latter should charge themselves with the duty of keeping the claims of Hospital Sunday before the former. No

doubt, however, this can be better done where the work is organised, and where families in which all are likely to be absentees are methodically canvassed and the claims of the hospitals laid before them. It is suggested in the article referred to that each parish adopting this plan should have a chairman, honorary secretary, and treasurer as permanent officers of its hospital committee responsible for the organisation of a body of workers in the cause. Perhaps it will not be too late in some places to initiate such a scheme in time to obtain a few contributions to the Fund before this year's subscriptions are sent in. At any rate the idea should not be allowed to drop, and we would add the suggestion that where there is any unreadiness on the part of those not members of the Church of England to be canvassed by neighbours representing the parish church, and associated with it, the members of other congregations should be able to organise collecting committees of their own, and thus to insure that no possible subscriber may be overlooked.

"SILENT PERITONITIS" AND SUDDEN DEATH.

AT a recent meeting of the Société Médicale des Hôpitaux de Paris M. Jean Minet called attention to acute peritonitis as a cause of sudden death which might go unrecognised. As a rule acute peritonitis—whatever its cause—produces such disturbance that it cannot pass unperceived, and the term latent peritonitis is applied only to the early stages of chronic peritonitis. It is difficult to believe that acute peritonitis can cause sudden death, in the strictest sense of the word, without betraying its existence in the slightest manner. But this occurred in the three following cases.

A soldier, aged 46 years, who performed clerical work, was found dead in his bed at 2 A.M. On the previous day, on the visit of the medical officer, he complained of pains on micturition. "Pyuria with albuminuria" was found and rest was ordered while awaiting a complete examination of the urine. According to his comrades he did not appear ill and he worked a little though exempt. He dined as usual and went to bed at the same time as the others. It was by accident that he was found dead. At the necropsy, performed on the following day, a large green patch extended over the distended abdominal wall. The peritoneum contained about a litre of reddish fluid and was covered with false membrane of recent formation, which bound together the coils of intestine. The true pelvis was walled off by a mass of old, thick, hard adhesions which enclosed the appendix. These adhesions limited an oval orifice 6 cm. in diameter, through which coils of small intestine passed into the pelvis. On being drawn out there was found 2½ metres of intestine of the colour of wine lees covered with hæmorrhages and showing a deep groove of strangulation at each end. The other abdominal organs were congested, especially the liver and kidneys. The right kidney contained a tuberculous mass of the size of a hazel nut. The bladder was full of purulent urine.

In the second case the patient was a soldier, aged 45 years, who worked in a munition factory. He came to hospital complaining of dyspnœa and cough. Râles were heard in the chest, especially at the bases of the lungs. He was put to bed. Cupping and cardiac tonics were prescribed and towards evening he slept. He was found dead in bed next morning. This sudden death of a man who manipulated dinitrophenol aroused suspicion of pulmonary œdema due to poisoning. At the necropsy œdema of the whole of the lower limbs and hands was observed. The skin was of a deep yellow colour. The lungs were congested at the bases but not œdematous. The abdomen contained about a litre and a half of purulent fluid and a recently formed false membrane uniting the intestinal coils to one another. A large mass surrounded the cæcum and adjacent intestinal coils and united them to the abdominal wall. In the centre was the appendix divided into two parts by a sort of strangulating groove. The proximal part was dilated and contained thick pus in which floated a stercoral concretion. There were "large white kidneys."

In the third case a man was knocked down by a kick in the abdomen. He fainted, but after a little time was able to go home. After resting he felt quite well, and went to the police-station to complain. On the following day he went to work and did not, according to his wife, complain of any pain. On the fourth day, after some vague malaise, he vomited greenish fluid, lay down, and died in a few minutes. The necropsy showed the peritoneal cavity full of fæcal matter and puriform fluid, and two perforations of the small intestine which had all the characters of a burst; the mucous membrane was everted, the orifice was irregular, and there was slight surrounding ecchymotic infiltration. There were no pathological changes in the intestinal coats. The abdominal wall showed no signs of injury. The assailant was prosecuted but acquitted, as M. Minet could not swear positively that the kick was the cause of the peritonitis.

In these three cases the peritonitis was completely "silent" during life, and the sudden death may be described as monosymptomatic of the condition. The point does not seem to have been noticed by medical jurists.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Total Laryngectomy.

IN a communication recently addressed to the Academy of Medicine M. Moure reports on 15 cases of complete laryngectomy performed during the last 27 months, recalling how serious an operation it has been considered for many years, the mortality having reached 95 per cent. In contrast to this high mortality all M Moure's patients, operated on for malignant tumours of the vocal organ, recovered from the operation, though not all derived permanent benefit inasmuch as in several cases the tumours recurred. A large proportion of the operations were done on very grave cases in which the new growth had already extended beyond the larynx and invaded the neighbouring tissues—œsophagus and pharynx. As regards the technique of the operation, M. Moure does not consider it necessary to "exteriorise" the trachea to ensure free breathing and prevent entrance of blood into the respiratory passages. In his opinion this course prolongs unduly an operation already long. His own procedure includes the following stages. Gauze is packed between a cannula placed in the trachea and the wall of the trachea. After removal of the larynx the wound is flattened out so as to diminish as far as possible the slough following the operation. Afterwards the wound is dressed two or even three times a day. In order to avoid the chief danger—viz., the risk of relapse—the operation should be done early while the malign tumour is still encapsuled in the thyroid sheath.

Heliotherapy in the Treatment of Gunshot Wounds.

M. Cazin, in demonstrating before the Academy of Sciences the results of the sun cure of war wounds obtained during the summers of 1915 and 1916, gave his opinion that the method of Rollier should be widely introduced in the hospitals, as it could be carried out everywhere with no special installation. In a certain number of cases of fractures complicated with suppurative arthritis, in which amputation appeared to M. Cazin inevitable, a fairly rapid and complete recovery was obtained by the sun treatment. An extension of its judicious employment should tend to shorten the treatment in a great number of gunshot wounds, and diminish the proportion of the infirm and unfit.

Radio-stereoscopy.

War surgery is likely to benefit materially by a new discovery, brought to the notice of the Academy of Sciences by Professor d'Arsonval—viz., the radio-stereoscopic apparatus of Dr. Lièvre, by which a direct stereoscopic view is obtained of images projected on the screen. The surgeon is thus enabled to see projectiles in their actual perspective, to ascertain their relation to each other, and appreciate the distance separating his instruments from the projectiles. The action of a simple reverser also permits him without moving the patient to obtain a stereoscopic view from in front or from behind. The apparatus is eagerly awaited by the field ambulances.

Resection of the Hip for Arthritis following Gunshot Wounds.

M. Potherat communicated to the Society of Surgery a note from M. Guénard, in which the latter affirms his belief in the safety of resection of the hip, even when in a septic

condition, since his results on a series of eight cases showed 100 per cent. of recoveries. All the cases operated on arrived in a condition of acute osteo-arthritis, one of them three days, another five days, up to 40 days after infliction of the wound, in several cases symptoms of gangrene being already present. His chief concern was always the gravity of the infection. The head and neck of the femur, including the great trochanter, are removed, retaining, whenever possible, the small trochanter. Posterior access appears the more convenient. A vertical segment of the capsule is removed from its posterior aspect, avoiding in this way too rapid a closing of the incision. The limb is immobilised in a plaster case, including both hip and knee. It is wise to control carefully the duration of immobilisation and remove the case as soon as possible, for such highly infected cases easily acquire pressure sores. The immediate result of resection is to abolish threatening infectious complications.

Severe Wounds of the Foot.

M. Quénu reported to the Society of Surgery 30 observations on wounds of the foot treated in field ambulances by M. Chalier. In one of these cases the soft tissues alone were concerned; the 29 others were osteo-articular wounds. M. Quénu divides these wounds into total and segmentary; the latter again into transverse (the commonest), longitudinal and wounds of the arch (fairly infrequent). Transverse partial wounds are again subdivided into wounds of the forepart of the foot, in front of, or on the interline of, the mediotarsal; wounds of the posterior part of the foot; and wounds of the ankle. The total of 30 foot or ankle wounds showed 3 deaths, 1 from tetanus and 2 from gas gangrene; there were 10 total mutilations (amputation of the leg), 4 partial mutilations (partial amputation of the foot), while 13 recovered without mutilation. Wounds of the forepart of the foot were the most favourable, although they accounted for 1 death by gangrene. Wounds of the posterior part of the foot accounted for 1 amputation for septicæmia. The cases of ankle wounds resulted in 1 death and 5 amputations, those complicated by lesion of the calcaneum being especially grave. For wounds of the arch there was one amputation, and the "total" injuries were responsible for 1 death and 2 amputations of the leg. M. Delbet, from experience at a base hospital, declared himself in entire agreement with M. Quénu, especially on the distinction to be made between wounds of the anterior and of the posterior tarsus. Posterior fractures with shattering of the calcaneum were specially grave. In these cases attention must not be concentrated exclusively on preservation of the foot; it was sometimes better to amputate than to run grave risks for the patient in order to preserve a foot which might in any case be of little use to him. M. Sébileau stated that by avoiding immediate systematic operation and allowing the wound free discharge in large warm baths of saline or carbolated water, he had achieved the remarkable result of saving the foot and its functions in every case. In cases where total ablation of the foot was indicated and the wound rendered this course practicable, M. Potherat recommended Syme's disarticulation. It was an easy and rapid operation for the surgeon, could be performed even in a septic area, was easy to fit later with any kind of apparatus, and resulted in but slight shortening of the lower limb. This operation is therefore far superior to amputation of the leg. M. J.-L. Faure regarded wounds of the posterior tarsus as always grave and most serious when the astragalus was involved and its articulations laid open. Astragalectomy was, in his experience, not infrequently followed by amputation of the leg after months of suffering and fruitless attempts to preserve the foot.

Foreign Body in the Intestine.

M. Tesson showed to the Society of Surgery a kind of chaplet of 136 porcelain buttons (similar to those worn on hospital blouses). The man from whom it was taken was not mentally deranged but suffered from gastric trouble, and used the chaplet as a gastro-œsophageal mop, claiming to obtain relief from it. One day the thread broke and the chaplet disappeared into his stomach. M. Tesson saw the patient ten days later at the height of an attack of general peritonitis due to perforation. The foreign body, lodged in the small intestine near the cæcum, was extracted by enterotomy. Death occurred next day.

June 25th.

ZINC WATERS—THEIR POTABILITY AND GERMICIDAL EFFECT.

BY H. H. SCOTT, M.D., M.R.C.P., D.P.H. LOND.;
AND
W. W. JAMESON, M.D. ABERD., M.R.C.P., D.P.H. LOND.,
CAPTAINS, R.A.M.C.

IN September, 1915, analysis of the drinking water of a small depôt in the Aldershot Command revealed the presence of 3·44 parts of metallic zinc per 100,000. The question naturally arose whether or not this water should be passed for human consumption. In November, Dr. J. C. Thresh contributed an article to THE LANCET[1] in which he recorded an instance where 2·3 parts of zinc per 100,000 had apparently caused no disturbance of health in a mixed community during a period of 10 years. An editorial note in the same issue referred to another case where some 4·6 parts of zinc were discovered in a public supply in Wales.

Source and Zinc Content of the Water.

In view of these experiences it was decided to pass the depôt supply for the time being, to notify the medical officer of the existing state of affairs, and to keep the water itself under fairly close supervision. This water has been the sole drinking supply for some 200 men for two years. During that time the health of the troops has been excellent, with the exception of one small outbreak of colic and diarrhœa involving only nine men in all. It proved impossible to connect this outbreak in any way with the water-supply. Furthermore, the commandant's house, prior to the introduction of the present system, obtained its water from a very contaminated well in the neighbourhood, and the children of the household frequently suffered, among other things, from various forms of "sore-throat." Since the new supply has been laid on all such minor ailments have disappeared, and the household drinks with impunity a water which has a definite metallic taste, and which has on one occasion been proved to contain no less than 4·72 parts of metallic zinc per 100,000. The source of supply is a shallow well situated on a knoll in the midst of cultivated clay soil about 1000 yards from the depôt. The well is some 30 feet in depth and contains from 4 to 6 feet of water. A windmill pumps the water through 1000 yards of galvanised-iron piping to a reinforced concrete tower capable of holding two days' supply. Thence it passes by more galvanised-iron service pipes to various points within the depôt. In the case of the commandant's house—a distance of some 400 yards from the tower—water is stored prior to use in a large galvanised-iron cistern.

The following table shows the varying amounts of zinc as estimated gravimetrically from time to time:—

TABLE I.

Date.	Galvanised iron.	Metallic zinc, parts per 100,000.	Date.	Galvanised iron.	Metallic zinc, prts. per 100,000.
25/9/15	Old storage tank.	3·44	10/9/16	1000 yards piping.	3·02
28/9/15	1000 yards piping.	3·58	10/9/16	1200 ,, ,,	3·77
17/1/16	1000 ,, ,,	2·985	6/12/16	1000 ,, ,,	2·09
17/1/16	1200 ,, ,,	4·076	6/12/16	1200 ,, ,,	2·44
3/3/16	1000 ,, ,,	2·38	6/12/16	1400 ,, ,,	3·32*
3/3/16	1200 ,, ,,	3·18	8/1/17	1400 ,, ,,	4·72*
18/4/16	1000 ,, ,,	2·51	17/1/17	1400 ,, ,,	4·27*
18/4/16	1200 ,, ,,	3·2			

* Galvanised-iron storage tank as well. The last two samples were drawn in the early morning.

It will be noted that there is tendency for the amount of zinc to decrease. The incoming water in the tower yielded on last examination only 2·09 parts of zinc as compared with 3·58 parts some 15 months previously. The amount of zinc dissolved must, of course, vary with the duration of contact. The well water, which is quite free from zinc, is neutral in reaction, contains between 2 and 3 parts of free CO_2 per 100,000 and shows only two parts of temporary hardness out of a total figure of 9. Its zinc solvent power, as tested experimentally on ordinary zinc foil, is considerable. The

[1] THE LANCET, Nov. 13th, 1915, p. 1098.

zinc is evidently held in solution as a bicarbonate, as it is completely thrown down by continued boiling. Liming the well water prevents more than a trace of the metal being taken up. Such being the case, one would expect an increase only in temporary hardness the greater the distance the water flows through the various pipes. It is found, however, that the permanent hardness increases to a considerable extent as well, a fact not so easy of explanation. The figure for non-volatile solids rises as more zinc is dissolved.

Bacteriological Investigation.

Various bacteriological examinations of the water have been made. The following are average results obtained from (*a*) four samples of the well water and (*b*) a similar number of tap water containing about 4 parts of metallic zinc per 100,000.

TABLE II.

—	No. of colonies on agar in 48 hours at 37° C.	No. of colonies on gelatin in 72 hours at 22° C.	MacConkey's bile-salt lactose broth.
Well water ...	32	109	Lactose fermenters in from 0·1 to 1 c.c.
Tap water ...	3	88	Lactose fermenters absent in 40 c.c.

The presence of zinc in solution appeared to inhibit the growth of organisms flourishing at blood heat, especially those fermenting lactose, while it affected but little others growing on gelatin. It was also noted that the decrease in the number of organisms seemed proportionate to the increase in the amount of zinc taken up by the water.

In order to confirm the suspicion that the presence of zinc, taken up by the water in its passage from the well to the commandant's house, might be responsible for the marked reduction in blood-heat organisms in general and in *Bacillus coli* in particular, the following series of experiments were undertaken:—

1. A sample of the well water was obtained with the usual precautions and brought direct to the laboratory where it was placed in the refrigerator for a short period (3–4 hours) intervening between its arrival and the setting out of the test. The average quantity of zinc found by former examinations of the water from the commandant's house, as shown in Table I., has been between 3 and 4·5 parts per 100,000. Thirteen tubes were set up containing quantities of zinc sulphate varying from 1 to 7 parts (of the metal) per 100,000, in gradations of 0·5 part—i.e., 1, 1·5, 2, 2·5 ..... 7. In each of these tubes 10 c.c. of the well water were placed. At the same time control agar plates were poured in order that the number of colonies developing in 48 hours at 37° C. might be accurately estimated for the sample on this particular occasion. The 13 tubes were then placed also at 37° C., and from each of them 1 c.c. was plated out in agar at the end of 24, 48, and 72 hours' contact, and counted 48 hours later, as in the control plate.

The objects of this experiment were, clearly, to see what effect, if any, the presence of definite quantities of a known salt of zinc might have on a water the bacterial content of which was known, and also to note whether more prolonged contact would increase the bactericidal effects, if present. The longest time during which the water in question could be in contact with the zinc being three days, this period was the limit employed in our experiments. The control plate yielded a count of 51 colonies, and the following Table III. gives the result of the test.

TABLE III.

Experiment 1.—Well water 10 c.c. and varying amounts of $ZnSO_4$. Control plates showed that the water contained 51 organisms per c.c. developing at 37° C. in 48 hours.

Quantity of zinc in parts per 100,000.	No. of colonies per c.c. developing in agar in 48 hours. After 24 hours contact.	After 48 hours contact	After 72 hours contact.	Quantity of zinc in parts per 100,000.	No. of colonies per c.c. developing in agar in 48 hours. After 24 hours contact.	After 48 hours contact.	After 72 hours contact.
1·0	7	0	0	4·5	1	0	0
1·5	6	0	4	5·0	0	0	0
2·0	6	0	1	5·5	0	0	0
2·5	3	0	0	6·0	0	0	0
3·0	1	0	1	6·5	1	1	0
3·5	5	0	2	7·0	1	0	0
4·0	2	0	2				

There is no need to elaborate the findings expressed in the table, the facts are eloquent in themselves.

2. The next experiment was as follows: A similar series of 13 tubes was prepared with the same increasing quantities of zinc sulphate, but in place of the natural well water, sterilised water was used, and a definite number of *B. coli* was added to each. A control plate of the sterile water and the *B. coli* was poured at the same time in order to give us an estimate of the number of organisms we were adding. It was our intention to add as nearly as practicable the same number of known organisms (*B. coli*) as there were bacteria developing at 37° C. in 48 hours from 1 c.c. of the well water sample. This latter, as stated above, proved to be 51; our control of the emulsion used showed 106 colonies, near enough to allow of comparable estimation.

Thus we had a series of tubes containing each 10 c.c. of sterilised water with approximately 100 *B. coli* organisms per c.c., and quantities of zinc varying from 1 to 7 parts per 100,000. These were placed in the thermostat at 37° C. as was done in Experiment 1, and plates were poured from each at the end of 24, 48, and 72 hours respectively. The plates were then incubated for 48 hours in each case and the numbers of colonies which developed were enumerated. The tabulated results are here given:—

TABLE IV.

Experiment 2.—Sterile water containing varying quantities of $ZnSO_4$ and a definite number of *B. coli*. per c.c.

Quantity of zinc in parts per 100,000.	No. of colonies per c.c. developing in agar in 48 hours. After 24 hours contact.	After 48 hours contact.	After 72 hours contact.	Quantity of zinc in parts per 100,000.	No. of colonies per c.c. developing in agar in 48 hours. After 24 hours contact.	After 48 hours contact.	After 72 hours contact.
1·0	62	0	0	4·5	5	1	0
1·5	280	0	0	5·0	4	0	0
2·0	149	0	0	5·5	3	1	0
2·5	158	0	0	6·0	1	1	2
3·0	72	1	1	6·5	4	0	0
3·5	57	1	0	7·0	4	0	0
4·0	8	0	1				

The high figures with tubes 2, 3, and 4 compared with 1 and 5 after 24 hours contact are probably due to accidental contamination when pouring the plates, especially since we notice that there was no growth from these same tubes after another 24 hours contact. This explanation is further substantiated by the fact that many of the colonies which grew on these plates were examined and found not to be *B. coli* at all, the only organism which had been added intentionally.

The noteworthy point, however, is the marked fall in the number of colonies developing from the tube containing 4 parts of zinc, which fall is maintained for the remainder of the series.

A question of autolysis of bacteria may be raised here, and there is no doubt that in the absence of any nutriment (the organisms having been added to sterilised water) a certain amount of autolysis must have occurred, but whether sufficient to reduce the original number to any appreciable extent was left for a subsequent experiment. But, even then, autolysis cannot account for the very remarkable reduction from 57 colonies developing from the tube containing 3·5 parts per 100,000 to 8 in that containing 4 parts. Further, it will be noticed that after contact for 48 hours only 5 of the tubes yielded any growth at all, and then only one colony.

3. As a control to this last a second series was put up a week later on the same lines with a similar culture, using varying amounts of metallic zinc (the sulphate being the salt employed) from 1 part to 5 parts per 100,000. The results of this are given below.

TABLE V.

Experiment 3.—Repetition of Experiment 2.

Quantity of zinc in parts per 100,000.	No of colonies per c.c. developing in agar in 48 hours. After 24 hours contact.	After 48 hours contact.	After 72 hours contact.	Quantity of zinc in parts per 100,000.	No. of colonies per c.c. developing in agar in 48 hours. After 24 hours contact.	After 48 hours contact.	After 72 hours contact.
1·0	65	3	0	3·5	0	0	1
1·5	15	0	0	4·0	2	0	3
2·0	41	0	0	4·5	0	0	0
2·5	59	1	1	5·0	0	1	0
3·0	21	1	0				

The only difference to note between these findings and the previous ones in that the drop in the first took place between 3·5 and 4 parts per 100,000, whereas in the latter it occurred at about 3 parts,

4. Our next experiment was arranged on lines somewhat similar to the last, but instead of varying the proportion of

zinc present, graded amounts of *B. coli* were added to the sterile water which contained the fixed quantity of 4 parts of zinc per 100,000 (i.e., the amount which has been found in water under investigation). The numbers of *B. coli* varied from 40 per c.c. in the first tube to 4000 in the last.

As in the previous experiments the tubes were placed at 37° C. and at the termination of 24, 48, and 72 hours plates were poured, and these after a further 48 hours incubation were examined and the numbers of colonies developing were counted.

TABLE VI.

Experiment 4.—To show the effects of the zinc on graduated numbers of *B. coli*, on the analogy of the previous experiments.

No. of *B. coli* per c.c.	No. of colonies per c.c. developing in agar in 48 hours.			No. of *B. coli* per c.c.	No. of colonies per c.c. developing in agar in 48 hours.		
	After 24 hours contact.	After 48 hours contact	After 72 hours contact.		After 24 hours contact	After 48 hours contact	After 72 hours contact.
40	7	0	0	800	102	0	0
200	103	3	—*	2000	189	0	0
400	69	0	0	4000	316	0	1

* Plate contaminated; overgrown by mould.

Undoubtedly here also the question of autolysis would come into consideration (VI.). In connexion with this experiment it is a point worth noting that the well water by previous analyses might show 50 colonies per c.c. or thereabouts, while that from the commandant's house on the same day had as few as 5 or 6, a reduction closely approximating that found by the experiment above.

With a view to elucidating the question as to the degree in which autolysis might be the cause of the reduction in Experiments 2 and 3, several series were put up, as in these experiments, but without any zinc, merely sterile water and *B. coli* in varying quantities, and estimated by the same method of incubating for 48 hours plates poured after the bacilli had been in the water for 24, 48, and 72 hours. The results were too variable to be worth recording; in some of the tubes there appeared to be but very little reduction at all within the times specified, while in others the numbers of organisms developing were considerably less, while yet again in others the plates showed some increase. The results of different experiments revealed different findings even with practically the same number of added organisms. There is no need, therefore, to give the details of these results; suffice it to say that in no instance was the reduction anything approaching that found in the zinc water experiments.

5. Finally, we considered that it would be instructive to use for experiment the water from the commandant's house with the zinc content in its natural state, instead of employing sterile water and artificially prepared $ZnSO_4$ solution. The water on this occasion yielded 4 colonies per c.c. growing in agar in 48 hours, and contained between 4 and 5 parts of zinc per 100,000. Varying numbers of *B. coli* were added as in Experiment 4, and plating was performed after further contact for 48 and 72 hours. The results obtained are presented in the following table:—

TABLE VII.

Experiment 5.—To show the effects of zinc in the water taken from the commandant's house after contact with varying quantities of *B. coli*.

No. of *B. coli* added per c.c.	No. of colonies per c.c. developing in 48 hours in agar.	
	After 24 hours contact.	After 72 hours contact.
20	2	0
100	35	0
200	47	0
500	55	1
1000	65	2

The times of contact were determined upon by the fact that the water as used is generally left for 24 hours and might conceivably be stored for as long as three days.

Summary and Conclusions.

1. During a period of two years a depôt of some 200 men has had as its sole supply a water proved to contain zinc in amounts varying from 2·5 to 4·72 parts of the metal per 100,000. No disturbance of health has resulted.

2. In one household the disappearance of a persistent condition of ill-health, attributed locally to a contaminated water-supply, coincided with the laying on of a water containing considerable quantities of zinc.

3. The number of organisms developing at blood heat from the well water is markedly greater than that found in the same water after it has taken up from 3 to 4 parts of metallic zinc per 100,000, and remained in storage for two days at most.

4. In order to ascertain whether or not this inhibitory effect on bacterial growth might be due to the zinc content of the water various experiments were undertaken.

5. From 3 to 4 parts of metallic zinc (as sulphate) appear to be sufficient, after 24 hours contact, to inhibit, if not destroy, coliform organisms in numbers considerably exceeding those likely to be found in any ordinary drinking supply (Experiment 2).

6. Even as small an amount as 1·5 parts of metallic zinc (as sulphate) per 100,000 renders such water practically sterile in 48 hours (Experiments 2 and 3).

7. The use of a water containing zinc naturally in solution as a carbonate shows analogous results, but, as would be expected, the reduction in the number of coliform organisms after the first 24 hours is not so great, though complete sterilisation appears to take place between 48 and 72 hours.

URBAN VITAL STATISTICS.

(Week ended June 23rd, 1917.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 17,000,000 persons, the annual rate of mortality was 12·4, against 12·7 and 12·8 per 1000 in the two preceding weeks. In London, with a population exceeding 4,000,000 persons, the death-rate was 12·2, or 0·1 per 1000 below that recorded in the previous week; among the remaining towns the rates ranged from 4·7 in Wimbledon, 4·8 in Ealing, and 5·3 in Barnsley to 20·5 in Bury, 21·0 in South Shields, and 21·6 in West Bromwich. The principal epidemic diseases caused 316 deaths, which corresponded to an annual rate of 1·0 per 1000, and included 179 from measles, 54 from infantile diarrhœa, 42 from whooping-cough, 31 from diphtheria, 8 from enteric fever, and 2 from scarlet fever. The deaths from measles showed a further decline compared with the numbers registered in the three preceding weeks, and caused the highest annual death-rates of 4·3 in South Shields, 4·5 in Middlesbrough, 5·2 in Walsall, and 7·0 in West Bromwich. The 587 cases of scarlet fever and 1067 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 14 and 22 below the numbers remaining at the end of the previous week. Of the 4032 deaths from all causes in the 96 towns, 259 resulted from violence. The causes of 33 deaths were uncertified, of which 6 were registered in Birmingham and 3 each in London, Liverpool, Sunderland, and Rhondda.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual death-rate was equal to 13·8, against rates declining from 17·0 to 14·7 per 1000 in the five preceding weeks. The 337 deaths in Glasgow corresponded to an annual rate of 15·7 per 1000, and included 35 from whooping-cough, 18 from measles, 7 from infantile diarrhœa, 3 from diphtheria, and 1 each from enteric fever and scarlet fever. The 72 deaths in Edinburgh were equal to a rate of 11·3 per 1000, and included 4 each from measles and whooping-cough, and 1 from diphtheria.

Irish Towns.—The 133 deaths in Dublin corresponded to an annual rate of 17·4, or 0·4 per 1000 less than that recorded in the previous week, and included 3 from measles and 1 each from scarlet fever and infantile diarrhœa. The 91 deaths in Belfast were equal to a rate of 12·1 per 1000, and included a fatal case of measles.

VITAL STATISTICS OF LONDON DURING MAY, 1917.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 3·5 per 1000 of the population, estimated at 4,237,287 persons; in the three preceding months the rates were 4·2, 4·4, and 3·7 per 1000 respectively. The lowest rates last month were recorded in Paddington, Hammersmith, the City of Westminster, Hampstead, and the City of London; while the highest rates were recorded in Shoreditch, Bethnal Green, Southwark, Bermondsey, Deptford, and Woolwich. Scarlet fever was rather more prevalent than it had been in the preceding month; among the several metropolitan boroughs the greatest proportional prevalence of this disease was recorded in St. Marylebone, Hackney, Finsbury, Shoreditch, Southwark, Bermondsey, Battersea, and Wandsworth. The Metropolitan Asylums Hospitals contained 613 scarlet fever patients at the end of last month, against 811, 785, and 712 at the end of the three preceding months; the weekly admissions averaged 92, against 102 and 93 in the two preceding months. The prevalence of diphtheria showed a decline from that recorded in other recent months; this disease was proportionally most prevalent last month in Stoke Newington, Holborn, Shoreditch, Bethnal Green, Poplar, Southwark, Bermondsey, Greenwich, and Woolwich. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1453, 1367, and 1206 at the end of the three preceding months, had further declined to 1048 at the end of last month; the weekly admissions averaged 129, against 165, 161, and 142 in the three preceding months. The prevalence of enteric fever was slightly in excess of that recorded in the preceding month; of the 39 cases notified during May, 5 belonged to Islington, 5 to Wandsworth, and 3 each to St. Pancras, Poplar, and Camberwell. There were 27 cases of enteric fever under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 29 and 25 at the end of the

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING MAY, 1917.

* Including membranous croup.

two preceding months; the weekly admissions averaged 6, against 6 and 4 in the two preceding months. Erysipelas was proportionally most prevalent last month in Holborn, Shoreditch, Bethnal Green, Poplar, Southwark, Battersea, Deptford, and Woolwich. The 15 cases of puerperal fever notified during the month included 3 in Southwark, 2 in Fulham, and 2 in Camberwell. Of the 44 cases of cerebro-spinal meningitis, 6 belonged to Bethnal Green, 4 to Wandsworth, 4 to Lewisham, 3 to Deptford, and 3 to Woolwich; while the 4 cases notified as poliomyelitis belonged respectively to Islington, Stepney, Southwark, and Lambeth.

The mortality statistics relate to the deaths of persons actually belonging to the several metropolitan boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the five weeks ending June 2nd the deaths of 5632 London residents were registered, equal to an annual rate of 13·9 per 1000; in the three preceding months the rates had been 21·3, 18·3, and 18·2 per 1000 respectively. The death-rates last month ranged from 9·1 in Hampstead, 10·9 in the City of London and in Lewisham, 11·2 in Wandsworth, and 12·2 in Battersea; the highest rates were 16·1 in Poplar, in Southwark, and in Bermondsey, 16·2 in Kensington, 16·3 in Stoke Newington, 16·4 in St. Marylebone, 16·8 in St. Pancras, and 17·2 in Holborn. The 5632 deaths from all causes included 480 which were referred to the principal infectious diseases; of these, 291 resulted from measles, 5 from scarlet fever, 44 from diphtheria, 59 from whooping-cough, 8 from enteric fever, and 73 from diarrhœa and enteritis among children under 2 years of age. No death from any of these diseases was recorded last month in the City of London; among the metropolitan boroughs they caused the lowest death-rates in the City of Westminster, Chelsea, Hampstead, Hackney, and Woolwich; and the highest rates in Paddington, Kensington, Hammersmith, Stoke Newington, and Holborn. The 291 deaths from measles were 111 in excess of the corrected average number in the corresponding period of the five preceding years; this disease was proportionally most fatal last month in Paddington, Kensington, Hammersmith, St. Pancras, Stoke Newington, and Holborn. The 5 fatal cases of scarlet fever were 16 fewer than the corrected average number, and included 1 each in Kensington, Hammersmith, Islington, Southwark, and Camberwell. The 44 deaths from diphtheria were equal to the corrected average, and included 5 in Deptford, 4 in Southwark, 4 in Wandsworth, 4 in Camberwell, 3 in Shoreditch, and 3 in Poplar. The 59 fatal cases of whooping-cough were 79 below the corrected average number, and included 6 in Islington, 5 in Hackney, and 4 each in Kensington, Shoreditch, Poplar, Lambeth, and Camberwell. The 8 deaths from enteric fever showed a decline of 3 from the corrected average, and belonged respectively to Kensington, Fulham, Chelsea, St. Pancras, Poplar, Battersea, Camberwell, and Lewisham. The 73 fatal cases of diarrhœa and enteritis among children under 2 years of age were 18 below the corrected average number; the greatest proportional mortality from this cause last month was recorded in Fulham, Shoreditch, Bethnal Green, Stepney, and Bermondsey. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was 1·0 per cent. below the average.

BABY WEEK.—From July 1st to 7th special efforts will be made throughout the country to bring home to the people the pressing need for conserving child-life, and by means of processions, pageants, lectures, and exhibitions it is hoped that the movement, which has already produced such good results by the establishment of maternity and child welfare centres, may be still further extended. In London on July 2nd in the Guildhall a resolution defining the policy of Baby Week will be proposed. It will run as follows:—

> In view of the overwhelming necessity for saving infant life at a time of unparalleled drain on the manhood and womanhood of the nation, the citizens here assembled earnestly call for the cooperation everywhere of municipal and voluntary enterprise to secure the following objects and pledge themselves to do their utmost in their respective localities for the furtherance of the same: (1) a full-time health visitor, under the control of the local medical officer of health, for every 400 babies in the area; (2) an approved infant welfare centre within the reach of every working-class home; (3) ample facilities for the antenatal care of mothers; (4) medical supervision of children between two years and school age.

On the same day Her Majesty the Queen will open in the Central Hall, Westminster, a child welfare exhibition, where everything that concerns the practical nurture and training of the child will be exhibited to the eye, while a series of conferences will also take place dealing with midwifery, illegitimacy problems, the care of the unmarried mother and her child, and other cognate subjects. Sir Francis Champneys and Sir Robert Morant are among the chairmen, while the speakers will include Professor E. W. Hope, Dr. Janet Lane-Claypon, and Miss A. Gregory. One of the methods of propaganda which ought to be productive of good results is the prize essay scheme in connexion with the elementary schools, the subject for boys being "Why should I kill that fly?" and for the girls "How I mind our baby." The special attractions for provincial towns and villages include baby shows, perambulator parades, and exhibitions of various kinds relating to mothercraft. At the Heritage Crafts Schools, Chailey, Sussex, there will be a special demonstration of Montessori ideals in connexion with the Montessori Hospital School for Tiny Crippled and Suffering Children, when Mr. Robert Mond, the founder of the Infants Hospital, Vincent-square, London, will preside and Professor Cyril L. Burt will give a short address. The address of the Executive Council for Baby Week in London is 6, Hollesstreet, W. 1, and full information regarding the programme may be obtained from the secretary.

Correspondence.

"Audi alteram partem."

THE VARIATION IN THE SPECIFIC GRAVITY OF URINE AND ITS RELATION TO DISEASE.

To the Editor of THE LANCET.

SIR,—In the pressure of general or even special practice, the urinometer seems generally looked upon as a mere guide as to whether the physician is to go to the further trouble to test for sugar; and when this and albumin are absent and nothing is suspected which requires the skilled aid of the analytical chemist or the bacteriologist, other possible conditions are often either entirely neglected or are regarded as of little value as a further means to diagnosis. Such oversight is particularly to be deprecated with regard to so simple and valuable an aid as the systematic registration of specific gravities.

By long and careful observation I have come to the conclusion that urines of specific gravities below 1015, and in certain cases below 1030, extending over long periods are of more pathological importance than those containing a slight percentage of either albumin or sugar. In the former there is a greater or lesser retention of the toxins of katabolism or tissue waste, a retention which will vary with the specific gravity; in the latter, such toxins may be fully eliminated.

Nor may such low specific gravities always be the result of sclerotic kidney or of high blood pressure, but in many cases are probably due to kidneys neither diseased nor congested, but more or less functionally inactive to the elimination of any substances other than pure water, a condition which may be responsible for more chronic ailments and diseases of obscure etiology than is generally supposed.

The specific gravity 1015, which is generally considered normal and is usually passed over without question, is inadequate to carry off the toxins constantly accumulating in the systems of those who live too freely, and even double this figure would scarcely suffice to keep such cases in perfect health.

Children during convalescence from scarlet fever show little evidence of pathological change except in so far as albumin may appear in the urine. It is when the albumin has disappeared, and the child seems to have escaped all the after consequences of the fever, that the real mischief is taking place. It is at this period, not only in consequence of the disappearance of albumin, but also because of the diminishing quantity of normal urinary constituents, that the urine falls still lower in specific gravity and becomes practically negative to reactions, is frequently almost colourless, and, in fact, sometimes in that condition which mothers describe as—"beautiful, looks just as though it had come out of the tap."

It would thus appear that the more lasting injury caused by the toxins and high temperature of the preceding fever has fallen upon those cells in the kidney whose functions it is to exert a selective activity on the blood, and to eliminate the products of katabolism, and that these cells, mainly the tubular epithelium, after the excessive work which has been thrown upon them in the rapid katabolism of fever have now reached a stage of exhaustion or lowered vitality, and remain in this condition long after the glomeruli have recovered and the albumin has disappeared.

That the glomeruli should be the first to suffer injury and the first to recover seems difficult to explain, but the fact that albumin first appears in the urine and then disappears, followed by a diminution and sometimes an almost complete, or even an entire absence of those substances believed to be excreted by the tubular epithelium, seems plainly to indicate that such is the case.

But in the meantime metabolism is going on and the uneliminated products of katabolism are steadily rising in the blood, and their toxic effects will appear ere long—in one case as rheumatism, in another as chorea, or in another as an "-itis" somewhere in the tissues. The particular tissue selected for attack will, of course, be that one whose vitality has been most impaired by the previous fever, and this again will depend upon idiosyncrasy.

In scarlet fever cases such continued low specific gravities are lost sight of because they may not commence until after the child has returned to apparent health, and probably not until after the hospital is left, the discipline of which has given place to that indulgence at home which will naturally take place after the enforced absence, the free and careless diet hastening those changes in the kidney which often end in such disastrous consequences. Hence the importance of re-examination in these cases for months after convalescence, and careful living and dieting in the meantime.

The virus of scarlet fever is perhaps the best to take as an example of conditions which have a specific devitalising effect on the kidney cells, though it is possible that a vicious circle may be established by the katabolic toxins themselves, intensified by errors in diet, acting as a deterrent to the physiological activity of these cells by lowering their vitality—and this is probably the commonest cause in those cases where a specific toxin cannot be traced or where such toxin can no longer be considered to be in action.

It would thus appear that a group of associated disorders, such as those which result as the sequelæ of certain fevers, can be explained as originating from the same toxins—namely, the uneliminated products of katabolism.

Hence, such theory would be in accordance with the opinion of those writers who believe in the identity of the poisons, whatever these may be, setting up the rheumatism and chorea following scarlet fever, and including the affections of the tonsils and naso-pharynx under the same causative agent or agents would naturally relegate these as "avenues of infection" for only such toxins as those of the exanthemata or those of microbic origin. It is, however, possible that either tonsillar or dental toxins acting over long periods may exert a deleterious effect on the vitality of the kidney eliminative cells, and thus set up a vicious circle causing rheumatism and chorea and other ills much as the toxin of scarlet fever, which, though of shorter duration, is, of course, much the more virulent.

I am, Sir, yours faithfully,

Liverpool, June 21st, 1917. WILLIAM BRAMWELL.

THE LUMLEIAN LECTURES AND MEDICAL RESEARCH.

To the Editor of THE LANCET.

SIR,—Sir John Broadbent has given his impressions of some recent observations and conclusions of a small body of workers to whom, justly or unjustly, the term "new school" has been applied, and in the last sentence of his letter states that, "for the reasons given above I am unable to accept in its entirety the doctrine of auricular fibrillation." Considering this sentence with its full context, it may be that, in speaking of the "doctrine of auricular fibrillation," the reference is to the special conclusion that digitalis in this clinical condition has a very special action, but this point I leave aside for the moment. It is left to the reader to believe that Sir John Broadbent doubts the validity of the conclusion that fibrillation of the auricles, a well-known experimental condition, occurs in the human subject.

It is now seven years since I gave in full the evidence for the occurrence of fibrillation of the auricles in the human subject. The papers were published at a time when the cause of gross irregularity of the human ventricle was a matter of wide controversy, and they were published simultaneously with less exhaustive articles from workers in Vienna. I judge the effect of these papers as impartially as it is possible for me to do, and conclude that they carried conviction to all who were actively engaged in work upon the subject. The papers brought conviction because they contained an overwhelming weight of evidence, much of which has since been confirmed abundantly by other workers, and none of which has been called in serious question. At the present time the doctrine that auricular fibrillation occurs in the human being and is in man a common clinical condition is universally accepted by productive workers, and to me it seems superfluous to repeat the evidence, which is on available record. Judgment has been passed upon the conclusions by those who are competent to judge, and this judgment is entirely favourable: active workers who held other views of the causation of the condition abandoned those views when the new conclusion was formulated. No publication will shake the conclusion unless it records new facts directly which contradict it and

contains new and reasonable explanations of the manifold phenomena of the clinical condition so far described.

But it may be that Sir John Broadbent's reference is solely to the supposed specific action of digitalis. Upon this question his view is clearly stated: "It is not merely in auricular fibrillation that digitalis is of value. Any clinician knows the extraordinarily satisfactory results obtained from the administration of digitalis in cases of heart failure and dropsy associated with mitral incompetence, even when the pulse is quite regular and there is no question of 'auricular fibrillation.'" It is clear that if *one* clinician has such knowledge, digitalis has the action here credited to it. But the clinician must show the source of his knowledge; he must bring forward the evidence for his faith. In regard to digitalis, there is on record at the present time a large number of cases of auricular fibrillation in which the effects of the drug have been observed closely and in which the rate of the ventricle has been shown beyond doubt to be controlled by the drug. These observations have been conducted on scientific lines. There are few instances, probably no instances, in which a medicinal remedy has been more carefully explored in a given malady. Casual bedside observations are not to be weighed in the same scale. There is no comparable series in which, with a normal sequence of chamber contraction, digitalis has been shown to have a similar effect or, in fact, any striking beneficial effect. If Sir John Broadbent can compile such a series; if he can place on record a number of observations in which "extraordinarily satisfactory results" follow the administration of digitalis when the heart's action is regular; if he can show that these results come from the administration, and not from other factors in the patient's environment (as has been done in the case of those suffering from fibrillation), I for one will freely acknowledge that he has performed for mankind generally and for his fellow-practitioners a signal service. But the bald statement that it is so is valueless; the series is not now forthcoming, and until it is forthcoming the conclusion cannot gain acceptance.

When Sir John Broadbent discusses the meaning and effects of digitalis slowing in auricular fibrillation he shows that he is not conversant with the facts or with contemporary thought. He writes: "The irregularity of rhythm in the ventricle in auricular fibrillation is attributed, so far as I am aware without any sufficient evidence, to the irregular transmission of feeble, incoördinate stimuli from the flickering fibres of the fibrillating auricle, which one would not suppose capable of exciting a contraction in the ventricle. But even admitting this, how can the mere cutting off of a few nervous impulses from auricle to ventricle by itself restore the functional efficiency of a heart muscle which has broken down under stress?" Now it is true that the irregularity of the ventricle is attributed to irregularly transmitted impulses from the auricle; and for this there is very powerful, if not convincing, evidence. That these impulses are *feeble* is pure supposition; we have no knowledge of their strength and no right to suppose them to be feeble; yet this description, gratuitously introduced, becomes the main point of attack. That the impulses are nervous is similarly a gratuitous addition to the contemporary hypothesis; yet Sir John Broadbent complains that the "neurogenic doctrine has been exalted to a position of undue importance."

The "mere cutting off" of a few impulses has a restorative effect upon a ventricle working under stress precisely because it relieves that stress by slowing an accelerated ventricle. Sir John Broadbent can hardly deny either that the ventricle is slowed by digitalis when the auricle is fibrillating or that the efficiency of the ventricle is increased by a reduction of its accelerated rate. But yet he will have it that the beneficial action of the drug is not of this kind, but that it acts as a "pick-me-up" for the exhausted muscle. "Pick-me-up" is not a particularly precise term in speaking of cardiac functions, but it is to be gathered that an increase in the strength of the contractions or of the muscle tone is in his mind. In support of this view he quotes Professor Cushny. There is no evidence of either of these effects in the human heart, and the subject is dismissed in almost as many words by Professor Cushny. When Sir John Broadbent quotes Professor Cushny as having found the heart to be slowed "*by direct action on the muscle*," he should add that the author he quotes is referring to the special muscle of the auriculo-ventricular bundle and not to the muscle of the ventricle, and that the drug is supposed to act upon this special muscle, not as a "pick-me-up," but as a poison which depresses its power of conduction. The current explanation of digitalis slowing is that which I put forward in my original papers—namely, that it is the effect of heart-block produced in the A.-V. tissues. This conclusion has been accepted generally; it does not include the recently added hypothesis that the action is indirect through the vagi. That hypothesis is still very much *sub judice*, and constitutes, so it seems to me, the chief outstanding point upon which controversy is permissible. But the point will be settled when it is settled, not by argument, but by further observations.

In so far as there are two schools, an old and a new, in cardiology, there are two schools in the following sense. There is a small body of workers who spend their time and energies in the collection of new knowledge, a body of workers who insist upon proof to demonstration or an approach to that ideal. This school, if school it be, has been productive, some would say extremely productive, during the past few decades. There is, on the other hand, a large number of clinicians who speak and write largely upon questions of cardiac pathology, but who do not demand or seek exacting proofs, but are content, as far as these questions are concerned, with a more philosophic and therefore more indolent attitude. This school, if school it be, is sterile; it is sterile because of its method of thought and inquiry. This division of medical thinkers has always existed, always will exist, and between the two schools an undercurrent of opposition is inevitable; one reason of its being inevitable is that the worker who unearths new facts regards those facts as primarily his property; he has a special and deep interest in them; they are his own children; he resents their being mauled; he resents the scolding of those children by any childless neighbour who regards them as young ruffians who disturb his peace. Those who have children, from the intimacy of their knowledge of them and their surroundings, from their sympathy for them, are most competent to rear them; those who discover new facts are most competent, in most instances alone competent, to weave these facts into a harmonious setting in the mass of human knowledge.

I am, Sir, yours faithfully,

THOMAS LEWIS, M.D. Lond.

Military Hospital, Hampstead, June 24th, 1917.

AN ARMY MEDICAL RESERVE: A PROPHETIC PROPOSAL.

To the Editor of THE LANCET.

SIR,—On Dec. 8th, 1904, the *Times* published a letter from me on the subject of an Army Medical Reserve. The letter contained a scheme I promulgated for establishing "auxiliary military hospitals" in connexion with, and affiliated to, the great general hospitals throughout the Empire. The staff was to be furnished by the junior staff of each hospital whose name it would bear. The matter was placed before the War Office authorities and some correspondence ensued, but nothing was done. Lately the matter has come up again in a pamphlet by Sir J. K. Fowler, which you reviewed in your issue of June 2nd. This scheme is on all fours with my scheme (see the enclosed extracts from my letter to the *Times*). I am sure you will agree with me that it is interesting to-day to reproduce the views of more than 12 years ago, which are now being adopted. I am, Sir, yours faithfully,

GEORGE STOKER,
Major, R.A.M.C.

Q.A.M.H., Millbank, London, S.W., June 13th, 1917.

Extract of a Letter entitled, "An Army Medical Reserve," published in the "Times" on Dec. 8th, 1904.

Where, then, it may be asked, are the right men to be found—men of suitable age, with requisite knowledge and practice, with an up-to-date training, those who have no ties, domestic or professional, which would prevent them being called up suddenly for service? They are to be found in connexion with every general hospital throughout the Empire, especially those that have medical schools and nursing homes attached to them. There are always to be found connected with such institutions a number of fully-qualified men who have lately occupied the posts of house physician or house surgeon, or who are acting as demonstrators, or assistants in the out-patient or other departments, who, to use a medical phrase, "are waiting for the wards." These and some senior medical students are the class of men required in the work. They are all known to one another, are picked men who have the honour and credit of their school and hospital very much at heart.

The nurses will be found in the same place with the necessary qualifications and surroundings. The orderlies could be recruited from the St. John trained orderlies in the district around the hospital.

The scheme for an Army Medical Reserve that I proceed to outline consists in the organisation of a system which shall embrace a number of units called civilian auxiliary hospitals, to be set on foot in times of peace and called out for service in times of war and stress. These hospitals would be organised in connexion with, and affiliated to, the general hospitals throughout the Empire. Such institutions would afford an ample and continuous supply of efficient physicians, surgeons, and nurses.

It would perhaps simplify matters if I describe shortly the formation of such a unit in connexion with a London general hospital. Let us call it St. George's Civilian Auxiliary Hospital No. 1. It is suggested that each hospital should be organised and equipped to contain 200 beds, but be capable of expansion to accommodate nearly twice that number. It is a universal experience that medical and surgical work in time of war comes in rushes, either during epidemics or after great battles, and for this reason it is absolutely necessary that hospitals should be capable of expansion.

THE SIGNIFICANCE OF CAPILLARY MARKINGS IN PULMONARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—In THE LANCET of March 4th, 1916, I called attention to the significance of certain red surface-markings in the neighbourhood of the upper dorsal vertebræ and their relation to pulmonary tuberculosis. I now have further figures to offer.

Notes of 481 consecutive cases were taken, all of which have been notified to their respective sanitary authorities. 130 were seen in the out-patient department of the Manchester Northern Hospital for Women and Children, the cases over 15 years of age being females.

	Ages in years.		
	Under 6.	6–14.	Over 15.
Showing marks	25 ...	59 ...	21
,, none	3 ...	17 ...	5
	28 ...	76 ...	26

80 per cent. therefore of the tuberculous out-patients showed markings.

Notes of 351 consecutive cases were taken at the Glossop and Chinley Tuberculosis Dispensaries and include in each age-group both sexes. The cases were sent to the dispensaries by their own doctors or by the school medical officers, or were contacts. 288 showed no tubercle bacillus to the usual examination, and 63 were returned as positive.

	Ages in years.			
	Under 6.	6–14.	15–19.	Over 20.
Showing markings	14 ...	92 ...	18 ...	68
,, none	7 ...	55 ...	22 ...	75
	21 ...	147 ...	40 ...	143

The 63 cases which showed tubercle bacillus in the sputum are classified as folllows:—

	Ages in years.			
	Under 6.	6–14.	15–19.	Over 20.
Showing markings ...	1 (dead) ...	4 ...	1 ...	17 (1 dead)
,, none	2 ...	4 ...	2 ...	32 (11 dead)
	3 ...	8 ...	3 ...	49

Of the whole number, 57 per cent. showed the markings and 43 per cent. have no markings, whilst in those who were returned as having the tubercle bacillus in the sputum 36 per cent. had markings and 64 per cent. had none.

The incidence of the death-rate is three times as great in those free from the markings compared to those showing markings. I am, Sir, yours faithfully,

Manchester, June 21st, 1917. R. CRAWSHAW HOLT.

THE TREATMENT OF TONSILLAR INFECTION.

To the Editor of THE LANCET.

SIR,—In your issue of June 2nd Dr. F. J. Poynton rightly draws attention to the large part that tonsillar infection plays in rheumatism. The prevailing opinion, at any rate with regard to the etiology of the more chronic forms, is to consider them primarily due to sepsis of the teeth. How often the tonsils get overlooked it is impossible to hazard. It is surprising, when a routine examination is made, from how many tonsils purulent matter may be exuded. The tonsils are commonly regarded as filters which deal with the organisms of the mouth. Once they have become a cesspool their use as natural immunisers has gone and radical enucleation would seem to be the only course to pursue. The body thus loses a most valuable protective organ, which not even the prolonged use of a vaccine of the predominant organism, usually a short streptococcus, will entirely make good.

But the question arises, Is there no means of saving the tonsils? Dental surgeons are now making efforts to cope with pyorrhœa in order to save the teeth. Can no means be found to save the tonsils? With this object in view I have recently been making use of a Bier's cupping apparatus, specially adapted for tonsil application. With a little practice it can be readily applied, and though very uncomfortable the patient soon gets accustomed to its use and can even learn to apply the instrument himself. It is surprising with what ease by this means pus can be squeezed out from the tonsils. The method, systematically and regularly applied, should do much to cleanse badly infected tonsils and give them a chance of recovering their normal powers. In several instances patients have quickly realised the relief afforded and have been only too anxious to continue the treatment.

At the present moment scores of soldiers are being thrown out of action by subacute and chronic rheumatism, some few of whom become hopeless cripples. In order that physical and thermal treatment should be used to the best advantage the early and vigorous treatment of sepsis wherever it lies should be thoroughly undertaken, and no advantage should be made of the fact that spontaneous subsidence of the septic focus will very often occur, for just as often it does not, and constant recurrences of rheumatism are only too common after apparent cure in patients whose throats, sinuses, or other foci apparently, but do not really, clear up. I am, Sir, yours faithfully,

Bath, June 20th, 1917. G. HELY-HUTCHINSON ALMOND.

SEROUS IRIDO-CYCLITIS.

To the Editor of THE LANCET.

SIR,—In the report in your issue of June 23rd of the meeting of the Section of Ophthalmology of the Royal Society of Medicine not one word is mentioned of what I for many months past have looked upon as one of the prime factors in the causation of those cases of serous irido-cyclitis (keratitis punctata, &c.) which, through the admirable and thorough work of Mr. W. Lang and others, have been—and I consider correctly—put down as frequently the result of pyorrhœa alveolaris. This complaint, serous cyclitis, is common enough in both sexes, but, in my experience, is far more frequently met with in the female, and at any age, roughly speaking, between 35 and 65; it is not found in very young or very old and edentulous people. Women certainly outnumber men, yet that would not account for the difference in the proportion affected; they pay quite as much attention to their teeth as the opposite sex, yet they more frequently fall victims to this serious complaint—and it is a very serious one. Why is this? It is not due to a less-resisting power of the female sex, nor to any idiosyncrasy thereof, but the missing link is constipation, and of that I have no manner of doubt, no possible doubt whatever. Women are far more constipated than men; they are more sensitive on the matter, and do not like to be seen repairing to, or issuing from, lavatories; they from early girlhood often neglect themselves in consequence. Again, they take less exercise, drink less fluid, are more careful and finicking in their diet, avoiding coarse foods more than we do, and—except in the case of the modern young lady—they smoke less or not at all; all this conduces to a sluggish state of the bowels. So, consequently, ptomaines—or whatever they are—passing in equal degree into the alimentary canals of both sexes, stand a much better chance of being absorbed into the lacteals or blood-vessels of the gut and "coming out in the eyes."

This theory fits in with practical experience, for all these patients are constipated, both men and women, some of them very much so; or, if they say their bowels are regular and act daily, the motions will be found dry and hard, absorption of the more fluid part having taken place. The treatment, therefore, is comparatively simple: whatever one treats one must not neglect the bowels, the teeth, or the

tonsil crypts; magnesia or soda should be given every morning in plenty of hot water or hot tea, the first thing on rising; if in water, the juice of half a lemon or a few grains of powdered ginger make it more palatable and prevent griping. These patients are greatly benefited by this plan of campaign and their feeling of well-being as the bowels get to act daily is pronounced.

Serous irido-cyclitis—as Mr. Lang has pointed out—may come from almost any source of septic absorption, and I have recently been treating a married lady with this complaint who had a vaginal discharge with ulceration of the cervix as the only likely cause; and in another very interesting case in a man the *fons et origo malorum* seemed to be septic absorption from very badly ingrowing toenails, the matrix thereof being in a foul and ulcerated state; the removal of the offending nails was rapidly followed by improvement and cure. I am, Sir, yours faithfully,

Norwich, June 26th, 1917. S. JOHNSON TAYLOR.

PUBLIC HEALTH APPOINTMENTS.

To the Editor of THE LANCET.

SIR,—Many people interested in public health regret that at a time when the Ministry of Health is under consideration there is apparently an absence of any attempt to prevent the continuation of the evils of the past *régime*—notably, the absence of coördination of effort and the multiplication of minor public health "specialist's" posts—blind-alley occupations. The Council of the Society of Medical Officers of Health has pronounced against such posts, and yet advertisements are continually appearing for whole-time medical officers for child-welfare centres. The prospects held out by such appointments must at present and for some considerable time yet be unsatisfactory, not only from a financial but also from a clinical point of view. Although the salary offered is adequate for a recently qualified practitioner, yet it will not be sufficient in a few years when the medical officer finds it does not lead to a more highly remunerated post and has lost valuable years during which a private practice could have been built up. It cannot be reasonably urged that these appointments are similar to those of resident medical officers to hospitals and that they afford an excellent training for private practice. The clinical interest of child-welfare work, although considerable, is limited. Much better work will be done by a medical officer who has an opportunity of carrying out other public health work as well, especially the medical inspection of school-children—an arrangement essential for the adequate coördination of the work carried out for children.

At the present time, when there is a shortage of civilian medical practitioners, it would seem advisable to arrange for this work to be carried out temporarily by general practitioners over military age. This course would have the important advantage of not penalising the large number of medical officers already in public health who have left their homes to serve with the forces. When the Public Health Service is being built up, who will see that these men are not forgotten? I am, Sir, yours faithfully,

June 24th, 1917. EFFICIENCY.

*** There is a strong feeling that no new civil appointments should be permanently filled while the war is in progress.—ED. L.

THE LANCET, VOL. I., 1917: THE INDEX.

THE Index and Title-page to the volume of THE LANCET completed with the issue of June 30th will be ready in July. Owing to the continued shortage in the paper-supply, the Index will not be issued with all copies of THE LANCET, as was the custom prior to the War. Subscribers who bind up their numbers are requested to send a post-card to the Manager, THE LANCET Office, 423, Strand, London, W.C. 2, when a copy of the Index and Title-page will be supplied free of charge.

The War.

THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue:—

Killed.

Capt. C. A. Whittingham, R.A.M.C., attached Royal Fusiliers, qualified at Glasgow in 1916, and thereupon joined up.

Capt. S. Pool, M.C., R.A.M.C., attached Leicestershire Regt., qualified at Liverpool early in 1916, and shortly afterwards joined the R.A.M.C. The award of the Military Cross was announced in THE LANCET of Dec. 2nd, 1916, p. 959.

Died.

Lieut.-Col. F. W. H. D. Harris, R.A.M.C., was educated at University College, London, and qualified in 1880. He held appointments at the West Kent General Hospital, Maidstone, and at Teignmouth Infirmary, and was secretary of the R.A.M.C. Fund and Benevolent Society.

Capt. J. Neligan, R.A.M.C., qualified in Ireland in 1915, and joined the R.A.M.C. shortly afterwards.

Capt. F. H. Knaggs, R.A.M.C., was a student at Guy's Hospital, and qualified in 1887. He had held appointments at Gloucester Infirmary, at Guy's Hospital, and at Leeds Infirmary, and was in practice at Huddersfield. On joining the R.A.M.C. he became ophthalmic and aural surgeon at the Huddersfield Infirmary and War Hospital.

Wounded.

Capt. G. W. Armstrong, R.A.M.C., attached N. Staffs. Regt.
Capt. S. K. McKee, R.A.M.C.
Capt. C. A. Webster, R.A.M.C.
Capt. E. R. Mackay, Aust. A.M.C.
Capt. N. Prior, N.Z.M.C.
Capt. G. W. Watson, R.A.M.C., attached R.F.A.
Capt. C. D. Coyle, R.A.M.C., attached Hamps. Regt.
Capt. G. S. Glass, R.A.M.C., attached Hamps. Regt.
Capt. J. C. G. Glassford, Aust. A.M.C.
Capt. C. M. Samson, Aust. A.M.C.
Capt. E. B. Thomas, Aust. A.M.C.
Capt. R. C. Winn, Aust. A.M.C.
Capt. R. P. Smith, R.A.M.C., attached R. Lanc. Regt.
Capt. J. G. Sweeney, Aust. A.M.C.
Capt. C. J. L. Patch, R.A.M.C., attached R. West Surrey Regt.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualties among the sons of medical men are reported:—

Capt. E. N. Nicholson, Hussars, died from illness contracted in France, only son of Dr. A. Nicholson, of Brighton.

Second Lieut. W. H. G. Compton, Royal Field Artillery, killed in action, eldest son of Capt. W. H. Compton, R.A.M.C., of Brighton.

Second Lieut. W. A. Menzies, Royal Garrison Artillery, died of wounds, only son of Dr. J. A. Menzies, of Folkestone.

Second Lieut. C. D. N. Caleb, Devonshire Regt., killed in action, son of Dr. C. C. Caleb, Professor of Physiology, Medical College, Lahore, India.

Lieut. R. M. Herron, R. Sussex Regt., died of wounds, eldest son of the late Dr. J. Herron, of Green Lanes, London.

Capt. P. C. Taylor, London Regt., previously reported missing, now officially presumed killed, fourth son of the late Dr. H. Taylor, of Kennington, London, S.E.

Second Lieut. J. W. Spanton, Rifle Brigade, died of wounds, third and only surviving son of Mr. W. D. Spanton, F.R.C.S., of Hastings, and formerly of Hanley, Staffs.

Capt. A. F. Gulland, The Buffs, died of wounds, only surviving son of Surgeon-General A. D. Gulland, of Cheltenham.

Capt. F. L. Davy, Australian Imperial Forces, killed in action, only son of Lieut.-Col. H. Davy, C.B., R.A.M.C., of Exeter.

Second Lieut. H. B. Graham, Black Watch, killed in action, younger son of Lieut.-Col. R. B. Graham, V.D., R.A.M.C., of Leven, Fife.

FOREIGN DECORATIONS.

The following decorations have been conferred upon members of the staff of the Hôpital Auxiliaire 301, Royaumont, by the President of the French Republic:—

Médaille d'honneur des Epidémies en Or.—Miss Ivens, M.B., M.S. Lond., chirurgien-en-chef.

Médaille d'honneur des Epidémies en Vermeil.—Miss R. Nicholson, M.B., B.S. Dunelm, Mrs. J. A. Berry, M.B. Lond., Miss M. Ross, M.B., Ch.B. Glasg., Miss M. Wilson, M.B., Ch.B. Edin., chirurgiens; Mrs. Savill, M.B., Ch.B. Glasg., radiologiste; Miss E. Courtauld, L.S.A. Lond., anesthésiste.

OBITUARY OF THE WAR.

WILLIAM GORDON CUMMINGS, M.B., B.S. R.U.I., D.P.H.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain W. G. Cummings, who was killed in action last month, at the age of 36 years, was a native of Dungannon, co. Tyrone. Educated at Queen's College, Belfast, he graduated in 1903 M.B., B.S. of the Royal University of Ireland, obtaining later the Diploma in Public Health. After a resident appointment at the Richmond Hospital, Dublin, he settled in practice at Hanwell, where he had been for 12 years before joining the R.A.M.C. Territorial Force in January, 1915. He was struck by a shell which exploded in the dug-out in which he was attending to the wounded. His senior officer writes of Captain Cummings as a man on whom he placed the greatest reliance, who was always cheery under the most adverse circumstances.

WILLIAM TRENGWEATH HARRIS, M.R.C.S. ENG.,

LIEUTENANT, ROYAL ARMY MEDICAL CORPS.

Lieutenant W. T. Harris, who was killed on April 15th on the transport *Cameronia* in the Eastern Mediterranean, was 40 years of age, and the son and grandson of medical men, his father having been medical superintendent of Norwich City Asylum, and his grandfather in practice at Redruth, Cornwall. He was educated at Norwich Grammar School, taking his medical course at St. Thomas's Hospital and qualifying in 1903. After holding an appointment as assistant medical officer at Wakefield Asylum he settled in private practice in Chiswick, where he had a large panel practice, which sometimes employed 15 or 16 hours of his time daily. In February of this year he received his commission in the Royal Army Medical Corps and was sent to Egypt, which he was destined never to reach.

A fellow practitioner writes of Lieutenant Harris as a true friend and colleague, and one who devoted himself with great unselfishness to his poorer patients, supplying them in case of need with food and clothing as well as medicine. He was a well-grounded anatomist and sound practitioner, never at a loss in an emergency, extremely kind, gentle, sympathetic, and considerate. Apart from his professional attainments, he was a born musician and accomplished violinist, a cultured gentleman, and a fluent French scholar, so much so that his house was from the first open to Belgians in distress who could not converse in English—indeed, one of these, a chemist, resided with him nearly a year, and subsequently corresponded with him from France.

ARCHIBALD McKERROW RUSSELL, M.B., CH.B. GLASG.,

SURGEON, ROYAL NAVY.

Surgeon A. McK. Russell, who was reported missing, feared drowned, on the s.s. *Highland Corrie* sunk on May 16th, was 26 years of age, and son of Thomas Russell, of Newmains, Lanark. He was educated at Newmains School and Hamilton Academy, taking his medical course in Glasgow University, where he graduated in 1914. He held a resident appointment at the Western Infirmary, and at the beginning of August, 1914, he became a surgeon in the Royal Navy, serving for more than two years on the *Macedonia*, in which he was present at the Falkland Islands engagement. After having given up an earlier passage to a colleague he was returning for his second period of leave when the steamship on which he sailed was torpedoed. The boat on which he was being lowered capsized and he was last seen attempting to save a fellow passenger with her baby. His friend who reached this country safely tells of his keenness on his work and acute observation of life which tended greatly to mitigate the extreme monotony of their life at sea and its routine duties. Surgeon Russell was a keen cricketer.

GURTH SWINNERTON BLANDY, M.D., CH.B. EDIN.,

MILITARY CROSS,
CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain G. S. Blandy, who died on active service on April 24th at the age of 38, was the third son of Colonel W. P. Blandy, Royal Artillery. Educated at Sheffield Royal Grammar School and Edinburgh University, he graduated M.B., Ch.B. in 1902 and M.D. in 1912. While a student at Edinburgh University he was a member of the Volunteer Artillery, serving as a combatant in the South African War with the Imperial Yeomanry, when he was invalided with enteric fever. After graduating he filled resident posts at the Scarborough and Norfolk and Norwich Hospitals. On the outbreak of war he was senior assistant medical officer to the Middlesex County Asylum at Napsbury, where he had served from the opening of the asylum in 1905. He at once joined the Royal Army Medical Corps, serving first at home, then in Egypt and through the whole of the Gallipoli campaign, and finally in France. He was awarded the Military Cross in Gallipoli for "attending French and British wounded without cessation from 11 P.M. on 1st until midday on 2nd May, 1915, under rifle fire the whole time." He received shell-wounds on April 23rd to which he succumbed on the following day.

Captain Blandy's superior at Gallipoli writes of him as "first-class at his job; he never spared himself in any way"; while a combatant officer alludes to his loss as that of an old and staunch friend: "He never spared himself in his care of us, and it was indeed due to this unselfish habit of his that he came by the wound which resulted in his death." His chief at the County of Middlesex War Hospital, Napsbury, endorses this view of Captain Blandy.

ANOTHER RED CROSS HOSPITAL IN DUBLIN.

Arrangements are being made by the joint committee of the St. John Ambulance Association and the Co. Dublin Branch of the British Red Cross Association to equip and maintain another voluntary Red Cross hospital in Dublin. Premises have been secured at Glasnevin, and the preparatory work is nearly complete. The hospital will accommodate some 250 beds. It will be in surgical charge of Mr. Seton Pringle, surgeon to Mercer's Hospital, who has worked for several months in the Urgency Cases Hospital at Revigny.

In view of the present difficulty of transporting the wounded to Ireland, and the consequent fact that for several months past there has been an excess of hospital accommodation for soldiers in Dublin, the enterprise of opening a new Red Cross Hospital in Dublin requires some justification, for the managers of the Dublin Castle Red Cross Hospital, which has been working since early in 1915, cannot obtain ready and sufficient voluntary subscriptions.

THE subscriptions which have been given in connexion with the Scottish Blinded Sailors' and Soldiers' Hostel, Newington House, Edinburgh, now amount to £13,565.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

THE following appointments have been notified:—Deputy Surgeon-General O. W. Andrews to *New Zealand*. Fleet-Surgeon P. M. May to *Pembroke*, additional, for East London Recruiting District.

ARMY MEDICAL SERVICE.

Temp. Col. J. W. Bridges, Canadian A.M.C., vice Col. G. S. Rennie, and Temp. Col. H. A. Chisholm, D.S.O., Canadian A.M.C., vice Lieut.-Col. C. A. Peters, to be Assistant Directors of Medical Services.

Temp. Major F. B. Carron, Canadian A.M.C., to be Deputy Assistant Director of Medical Services.

Temp. Col. H. G. Barling (Lieut.-Col., R.A.M.C., T.F.), relinquishes his temporary commission on re-posting.

TERRITORIAL FORCE.

Lieut.-Col. H. Collinson, D.S.O., to be temporary Colonel whilst holding the appointment of Assistant Director of Medical Services.

Capt. A. Ramsbottom to be Deputy Assistant Director of Medical Services.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. O. L. Robinson, C.M.G., to be Brevet-Colonel on appointment as an Honorary Physician to the King.

Major R. B. Hole relinquishes the acting rank of Lieutenant-Colonel on re-posting.

D. B. King to be temporary Major whilst serving with the Horton (County of London) War Hospital.

Capt. L. R. Meech, M.C., to take rank and precedence as Captain as if his appointment to that rank bore date April 21st, 1917.

Temp. Capt. O. E. Farley, C.A.M.C., to take rank and precedence in the Corps and in the Army as if his appointment as temporary Captain bore date April 30th, 1917.

To be temporary Captains: Temp. Lieut. M. S. Fraser, M. H. Paterson, J. H. White, and Temp. Lieuts. L. J. O'Donovan, W. H. Marshall, T. G. Featherstonhaugh, J. Harvey, E. G. Saunders, J. Neligan, J. E. Ashby, A. Buchanan, W. L. O'Neill, J. L. Falconer, H. M. Jackson, J. P. Crawford, A. R. C. Doorley, R. M. de Mowbray, E. L. K. Sargent, W. Macadam, T. G. Evans, D. J. Harries, S. A. Burn, J. Keyms, E. H. Price, T. L. Jones, J. Cairns, W. G. Marsden, G. N. Brandon, A. M. A. James, A. E. Goldie, H. H. Fairfax, S. G. J. Dowling, F. Simpson, T. F. Wilson.

J. A. Gibb, late temporary Captain, to be Honorary Captain.

Officers relinquishing their commissions: Temp. Major R. C. Tweedy (on account of ill-health). Temp. Capts.: H. H. K. Sparrow, J. R. Robertson, J. E. Phillips, A. R. Roche, D. F. Kennard, E. E. Frazer, C. Coventry, C. H. Armitage, T. H. Phillips, H. Crichton. Temp. Lieut. C. W. Gittens (on account of ill-health).

SPECIAL RESERVE OF OFFICERS.

Major James C. Furness to be acting Lieutenant-Colonel whilst commanding troops on a hospital ship.

Lieut. (on probation) J. K. R. Landells is confirmed in his rank.

Lieutenants to be Captains: A. G. P. Wills, R. W. H. Miller, L. A. B. Moore.

To be Lieutenants: J. I. Keen (from University of London Contingent O.T.C.), D. Henegan (from Durham University Contingent O.T.C.), S. T. Alexander, C. G. G. Winter.

TERRITORIAL FORCE.

Lieut.-Col. F. Marsh is seconded whilst holding the appointment of Assistant Director of Medical Services.

Major J. E. H. Sawyer to be acting Lieutenant-Colonel whilst holding the appointment of Administrator.

Hon. Capt. F. C. Bentz (late Capt.) to be Captain, with precedence as from April 1st, 1915.

Capt. A. Ramsbottom is seconded whilst holding the appointment of Deputy Assistant Director of Medical Services.

Capt. J. M. A. Costello, to be acting Lieutenant-Colonel whilst commanding a Field Ambulance.

Lieut.-Colonel H. Collinson, D.S.O., is seconded whilst holding the appointment as Assistant Director of Medical Services.

Officers seconded for duty with a General Hospital: Capts. H. W. Wilson, J. H. Thursfield, and N. S. Finzi; Lieut.-Cols. E. M. Callender and T. W. Westmacott; Majors F. J. Steward and J. H. Ray; Capts. W. S. Colman, F. D. S. Jackson, and M. Horne; Major G. N. Biggs; Capts. E. R. Carling, A. J. Jex-Blake, D. H. de Souza, G. A. Ewart, J. Everidge, D. Douglas-Crawford, J. Hay, H. Armstrong, C. T. Holland, V. C. de Boinville, W. C. Oram, G. M. Benton, G. E. Loveday, J. Wharton, F. E. Tylecote, and R. Ollerenshaw.

Lieut. A. C. Smith to be Captain, and to remain seconded.

Attached to Units other than Medical Units: Lieut. B. T. L. Glover to be Captain.

VOLUNTEER CORPS.

Durham Volunteer Regiment (9th Battalion): N. Philipson to be temporary Lieutenant and Medical Officer.

Northern Counties Highland Volunteer Regiment (1/1st Battalion): D. McFadyen (Surgeon-Lieutenant-Colonel, late Cameron Highlanders), to be temporary Captain and Medical Officer.

INDIAN MEDICAL SERVICE.

The King has approved of the retirement of Brevet-Colonel Sir Bruce Seton, Bart. (in consequence of ill-health).

CANADIAN ARMY DENTAL CORPS.

Temp. Major A. L. Johnson, from a Canadian Infantry Battalion, to be temporary Captain.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—J. Hollings (Sections I and II.), London Hospital; and C. A. Mortlock-Brown (Sections I. and II.), Royal Free Hospital.

Medicine.—W. A. Bibby, Manchester; C. A. W. Chapman (Section I.), Sheffield; S. C. Ho (Section I.), Cambridge and London Hospital; C. de C. W. Langdon (Sections I. and II.), Manchester; G. W. Pratt (Sections I. and II.), Cambridge; and C. Segal (Section II.), Berne.

Forensic Medicine.—W. A. Bibby, Manchester; A. G. Curzon Miller, Middlesex Hospital; and G. R. Sharp, London Hospital.

Midwifery.—D. C. Clark, King's College Hospital; E. W. Diggett, Jefferson College, Philadelphia; L. Dinerstein, London Hospital; and A. Magill, Guy's Hospital.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: W. A. Bibby, J. Hollings, C. de C. W. Langdon, and C. A. Mortlock-Brown.

VICTORIA UNIVERSITY OF MANCHESTER.—At an examination held in June the degree of M.D. (with commendation) was conferred upon W. Howarth Parkinson.

CENTRAL MIDWIVES BOARD.—Special meetings of the Central Midwives Board were held at Queen Anne's Gate Buildings, Westminster, on June 19th and 20th, with Sir Francis H. Champneys in the chair. A number of midwives were struck off the Roll, the following charges, amongst others, having been brought forward:—

Being in attendance as a midwife at a confinement and the patient suffering from abdominal swelling and tenderness, the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, as provided by Rule E. 21 (4); the patient being in the condition aforesaid, the midwife did not hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E. 20, and medical aid having been sought for the patient she neglected to notify the local supervising authority thereof, as required by Rule E. 22 (1) (a). The midwife neglecting to take and record the pulse and temperature of the patient at each visit, as required by Rule E. 14; advising the patient to mislead the officers of the local supervising authority by abstaining from giving them information as to the condition of the patient; not being scrupulously clean in every way, as required by Rule E. 2; and not keeping her register of cases, as required by Rule E. 24. When attending a patient the midwife neglecting to wear a clean dress of washable material, and a clean washable apron or overall, as required by Rule E 2; neglecting to disinfect her hands and forearms on each occasion before touching the generative organs of the patient, as required by Rule E. 4; and neglecting to swab the patient's external parts with an efficient antiseptic solution before making the first internal examination, as required by Rule E. 8. Being in attendance at a confinement and the child suffering from inflammation of and discharge from the eyes and continuing so to suffer, the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, as provided by Rule E. 21 (5). Having been in contact with a person suffering from a condition supposed to be infectious, the midwife neglected to notify the local supervising authority of the fact, as required by Rule E. 6, and having been suspended from practice by the local supervising authority, in accordance with Section 8 (3) of the Midwives Act, 1902, and Rules F. 1 and 2 of the Regulations of the Central Midwives Board, she nevertheless disregarded the suspension and continued to practise as a midwife without having undergone disinfection to the satisfaction of the local supervising authority, as required by Rules E. 6 and F. 2. A midwife fraudulently procuring the burial of two infant children by falsely representing that the contents of a box were truthfully described in a certificate made and written by her, whereas in truth and in fact the said box contained the bodies of two infant children as well as the body of a stillborn child, as she well knew, and that therein she was guilty of misconduct

within the meaning of Section 3, V. of the Midwives Act, 1902. A midwife being herself liable to be a source of infection from a septic finger, she attended a patient without having undergone the disinfection required by Rule E. 6; being liable to be a source of infection as aforesaid, she neglected to notify the local supervising authority, as required by Rules E. 6 and 22 (1) (e); she neglected to disinfect her hands and forearms on each occasion before touching the patient's generative organs, as required by Rule E. 4, and in disregard of Rule E. 8 she neglected to wash the patient's external parts with soap and water and to swab them with an efficient antiseptic solution (1) after the termination of labour; (2) during the lying-in period when washing was required. In contravention of the provisions of Section 1 (4) of the Midwives Act, 1902, the midwife employed her daughter, an uncertified person, as her substitute, to visit a patient during the latter part of the puerperium. The midwife not giving every reasonable facility to the local supervising authority for the inspection of her register of cases, bag of appliances, &c., and her place of residence, and an investigation of her mode of practice, as required by Rule E. 25. Being in attendance at a confinement and one of the twin children being stillborn, no registered medical practitioner being in attendance at the time of birth, the midwife neglected to notify the local supervising authority thereof, as required by Rule E. 22 (1) (c); the other twin child suffering from dangerous feebleness, she did not explain that the case was one in which the attendance of a registered medical practitioner was required as provided by Rule E. 21 (5), and the said child having died before a registered medical practitioner was in attendance, she neglected to notify the local supervising authority thereof, as required by Rule E. 22 (1) (b). The midwife neglecting to take and record the pulse and temperature of the patient at each visit, as required by Rule E. 14, and falsely and fraudulently recording in her temperature-book certain particulars purporting to represent the daily temperatures of the patient as taken by her, when in fact these records were entirely fictitious, no such daily temperatures having been taken by her or on her behalf.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the committee, held on June 12th, 21 cases were considered and £196 voted to 17 of the applicants. The following is a summary of certain of the cases relieved:—

Widow, aged 72, of L.F.P.S. Glasg. who practised at Rochdale and died in 1899. The little money left her by her husband now exhausted, and her only income is £1 per week from children, which has to keep her and a son, aged 51, who is a victim of the drug habit. She lives with a married daughter, who is in very poor circumstances. Voted £12 in 12 instalments.—Daughter, aged 57, of M.R.C.S. Eng. who practised at St. Day, Cornwall, and died in 1917. On the death of her father was left without means and her only income is now derived by acting as church organist and teaching music, which is very precarious. Pays £12 a year rent. Voted £12 in 12 instalments and referred to the Guild.—Widow, aged 33, of M.R.C.S. Eng., retired Captain, R.A.M.C., who practised at Caterham and died in March, 1917. Applicant's husband committed suicide, and her only income is the proceeds of an insurance policy. Has two children, ages 6½ and 4, and requires help towards their education. At present living with her father, who cannot afford to keep her. Voted £6 and referred to the Guild.—Widow, aged 39, of M.D. Glasg. who practised at Perth and died in 1916. On the death of her husband she endeavoured to sell the practice, but was not successful, as her husband had specialised in X ray work. Only income £56 a year from dividends. Has three children, ages 6–11. Lives in own house, but has to pay £16 a year for rates. Voted £10 in two instalments and referred to the Guild.—Widow, aged 33, of M.D. Dub. who practised at Redditch and died in March, 1917. Her husband was on civil military duty in North Wales and was awaiting a commission. He contracted acute pneumonia in the Army camp and died suddenly. Her only income is derived from investments on insurance money and produce about £60 per annum. There are two children, ages 1 and 4 years. Voted £10 and referred to the Guild.—F.R.C.S. Irel., aged 46, married, who practised in London. Applicant became infected with acute tuberculosis of the throat after examining a patient, and is now in a sanatorium. All his savings gone and unable to sell the practice, and only income a little allowed by his father-in-law. Voted £20.—Daughter, aged 44, of M.R.C.S. Eng. who practised at Notting Hill and died in 1885. Only income 5s a week allowed by sisters. Applicant quite incapable of earning her own living and her sisters unable to entirely provide for her. Her mother, who has recently died, was helped by the Fund for many years. Voted £5.—Daughter, aged 70, of M.R.C.S. Eng. who practised at Cranbrook and died in 1890. Applicant is quite incapable of working. Her income is only £46 per year, and she has to pay £1 per week for board and lodgings. Relieved 18 times, £182. Voted £12 in 12 instalments.—Daughter, aged 65, of M.R.C.S. Eng. who practised at Lydney and died in 1880. Lost the income left her by her father through a defaulting trustee. Too old to work. Only income £21 from another charity. Relieved 11 times, £116. Voted £12 in 12 instalments.—Daughter, aged 77, of M.R.C.S. Eng. who practised at Hackney and died in 1859. Applicant lost all her capital through a defaulting trustee. Has been operated upon several times for cataract. Only income £30 from another charity and £20 from friends. Pays £1 per week for board and lodgings. Relieved five times, £66. Voted £15 in 12 instalments.—Daughter, aged 65, of M.R.C.S. Eng. who practised at Liverpool and died in 1885. Applicant acted as matron at a mental nursing hospital for many years, but had to retire on account of rheumatism and deafness. Income from another charity and a dividend, £37. Relieved three times, £34. Voted £12 in 12 instalments.—Daughter, aged 53, of M.R.C.S. Eng. who practised at Box, Wilts, and died in 1894. In consequence of chronic ill-health unable to earn anything. Three sisters live together, only one of whom can work. One of the other sisters helped by the Fund. Relieved seven times, £96. Voted £12 in 12 instalments.—Widow, aged 62, of M.B. Dub. who practised in Acton and died in 1912. Applicant was left without means, but prior to the war her four children were able to help. Since the war, a son abroad, who used to pay her rent, has not always been able to help, and a daughter who lived with applicant broke her leg in February, and is still in hospital. Relieved four times, £25. Voted £10 in two instalments.—Widow, aged 52, of L.S.A. Lond. who practised at Leicester and died in 1910. Applicant was left without means, with four children, two of whom still go to school. The two eldest are now earning a little, but in consequence of applicant's ill-health and the high price of food cannot manage. Relieved five times, £60. Voted £12 in 12 instalments.—Daughter, aged 60, of M.R.C.S. Eng. who practised at Long Sutton and died in 1879. Applicant acts as housekeeper without salary, and her dividend is only £25 per year. Relieved twice, £24. Voted £12 in 12 instalments.—Widow, aged 70, of M.R.C.S. Eng. who practised in Jamaica and died in 1884. Applicant left without means. Has three children married with families, and unable to help. Income £26 from another charity, and a little help from friends. Pays 6s. per week rent. Relieved 12 times, £87. Voted £12 in 12 instalments.—Widow, aged 56, of M.R.C.S. Eng. who practised at Stockton-on-Tees and died in 1887. Applicant was left entirely without means, with two children to bring up. The son is now in the Army, and she gets 9s. 2d. per week Army allowance, and the daughter is a clerk, and allows her mother 14s. per week. Applicant has very bad sight. Relieved 13 times, £115. Voted £12 in 12 instalments.

THE King has appointed Mr. Edward Coker Adams a Member of the Executive Council and an Official Member of the Legislative Council of the Colony of the Gambia.

ORDER OF ST. JOHN OF JERUSALEM.—Mr. A. J. Johnston, M.R.C.S. Eng., L.R.C.P. Lond., has been promoted to Esquire in the Order of the Hospital of St. John of Jerusalem in England.

CENTENARIANS.—Mr. Thomas Weekes, of Ticehurst, has recently celebrated the 100th anniversary of his birthday, and Mr. C. Tearell, of Lympne, Kent, has died in his 102nd year.

INSANITY AND THE WAR.—In his report for the past year on Kingseat Asylum, Aberdeen, Dr. H. de M. Alexander notes that men belonging to the services who have become mentally affected through the war are accommodated in the war mental hospitals, so that it is fallacious to assume from any statistics that there is a decrease of insanity throughout the country meantime. The report goes on to say that "on the resident population here the war has had little effect. The majority are keenly interested in it and read the papers with avidity. They have taken the lighting restrictions philosophically and are not in the least perturbed by any scares. If detrimental effect has occurred at all, it pertains only to one or two egotistical paranoiacs into whose domineering speech has crept the curious braggadocio and phraseology characteristic of the Prussian."

DEATH OF WALTER JAMES HILL, L.R.C.P. LOND., M.R.C.S.—Mr. W. J. Hill, medical officer of health of Clevedon, Somerset, died recently at his residence in Clevedon from pneumonia, in his fifty-sixth year. The deceased was a student at the Bristol Medical School, and after holding several resident appointments at the Bristol Royal Infirmary, entered into partnership with the late Dr. S. Skinner, of Clevedon, and later succeeded to the practice. He held several public appointments and was medical officer of health of the town since 1902. He was also on the honorary medical staff of the Cottage Hospital, the local Dispensary, Walton Convalescent Home, and the Red Cross Hospital. Mr. Hill was surgeon-captain in the Gloucestershire Royal Garrison Artillery, T.F. He will be greatly missed in Clevedon, where he was highly respected, and much sympathy is felt there for his widow and daughter.

OXFORD OPHTHALMOLOGICAL CONGRESS, 1917.—This Congress will take place at Keble College, Oxford, on July 12th and 13th. On the evening of the 11th there will be an unofficial dinner in the hall of Keble College. On the morning of the 12th the Master of the Congress (Mr. Sydney Stephenson) will welcome the members in the Department of Human Anatomy, kindly lent for the purpose by Professor Arthur Thomson, and a discussion on "The Correction of Errors of Refraction" will be opened by Dr. George M. Gould, of Atlantic City, New Jersey, and Lieutenant-Colonel Robert H. Elliot. At 8.15 P.M. the official dinner of the Congress will take place, under the presidency of the Vice-Chancellor of the University of Oxford, the Very Reverend T. B. Strong, D.D., Dean of Christ Church; and at 9.15 P.M. there will be a general meeting to discuss the proposal of affiliation with the Ophthalmological Society of the United Kingdom. On the following day the programme is as follows:—Dr. Edridge-Green: "The Relation of the Theory of Vision to Ophthalmology."; Dr. George Young: "A Few Remarks on Clinical Tests of the Colour Threshold"; Lieutenant-Colonel R. H. Elliot: "On the Indian Operation of Couching"; Dr. D. V. Giri: "Ring Infiltration of the Cornea in a Case of Purpura"; Captain P. H. Adams: "Some Points on Retro-bulbar Neuritis." At 2.30 P.M. cases will be shown in the Eye Hospital, and at 3.30 there will be a discussion of the cases and remarks by Dr. Johnson Taylor and Captain R. J. Coulter. The scientific museum and exhibition will be open in the department of human anatomy on the two days. Members who purpose to be present should send the attendance fee (10s. 6d.) to the honorary secretary, Mr. Bernard Cridland, Salisbury House, Wolverhampton, without delay, and state whether they desire rooms reserved in Keble College.

Obituary.

ARTHUR WEBB JONES, M.D., B.S. LOND., F.R.C.S. ENG.,

SURGEON AND GYNÆCOLOGIST, GOVERNMENT HOSPITAL, ALEXANDRIA.

By the untimely death of Arthur Webb Jones the British community in Alexandria and numerous friends have sustained a great loss.

Dr. Webb Jones was educated at Malvern and St. Thomas's Hospital, and took the diploma of F.R.C.S. Eng. in 1900. He then worked for the degrees of the University of London whilst engaged in active practice in Egypt, and became B.S. in 1911 and M.D. in 1913. As the subject of his thesis for the latter degree he selected "Bilharziosis in Women," and on this difficult question he was able to write authoritatively, owing to his wide experience in gynæcological surgery in Alexandria. For five years, 1900–1904, Webb Jones served in the Egyptian Army in the Soudan; and on leaving that country in order to settle in private practice in Egypt he received the official thanks of the Governor-General of the Soudan for his services. His merits and abilities were recognised by his appointments as medical officer for the Alexandria district to the Egyptian State Railway and of surgeon and gynæcologist to the Government Hospital there.

During the Gallipoli campaign, when the medical and surgical resources of Egypt were taxed to the uttermost, Webb Jones volunteered and did yeoman service for the British troops from May, 1915, to December, 1916. With him it was a subject of much heart-searching that he was not in khaki, but it was on the assurance of the military authorities that he was doing excellent work and could not give better help that he refrained from applying for a commission. There is no doubt that his strenuous labours indirectly shortened his life, which was closed by one of those tragedies only too familiar to medical men. He had not been out of Egypt since 1913, and when an epidemic of typhus fever broke out this spring in Alexandria, it found him fatigued and somewhat out of health, though keen as ever upon his duties. He was called upon to give an intravenous injection of saline solution to a brother practitioner, dying from typhus, and accidentally inoculated himself in doing so. In about 10 days the disease showed itself, and despite the assiduous and affectionate care of Colonel Sandwith, consulting physician, E.E.F., of Captain Charles Walker, R.A.M.C., and other friends, he succumbed to the infection. His funeral was attended by representatives of every official and administrative branch with which he was or had been connected, and by many private friends.

Of his abilities as a surgeon Colonel A. H. Tubby, A.M.S., consulting surgeon to the Mediterranean Expeditionary Force, who had recent opportunities of forming an opinion, writes as follows: "Webb Jones was a sound diagnostician, and a resourceful and skilful operator. His judgment was good and his successes numerous. Looking through his notebooks we find his cases carefully recorded; and he was in the habit of adding his subsequent impressions and investigations to the account of each case, thus continually crystallising his experiences and perfecting his knowledge and technique. As a colleague he was all that one could desire, and happy were those who were admitted to his friendship. A winning manner, entirely free from any trace of self-assertion, a broad outlook on life, and an obvious sense of complete responsibility, combined to render him a tower of strength in trouble and illness. Had he been permitted to reach the allotted span of life he would have gone far. He leaves a widow and a young family and numerous friends to grieve at his departure."

THE death occurred on June 20th of Thomas Sheldon, M.D. Edin., M.R.C.S. Eng. He was in his 83rd year, and had been in practice in Kensington for 54 years. He qualified as M.R.C.S. Eng. in 1859, and M.D. Edin. in 1863. He was educated at University College Hospital, London, and at the University of Edinburgh. He had been resident physician at the Royal Infirmary, Edinburgh, under Dr. James Warburton Begbie, and later medical officer of the Kensington and Notting Hill Division of the Post Office. A justice of the peace for the County of London, he was the eldest son of William Sheldon, J.P., of Stratford-on-Avon. Two of his sons are in the medical profession, the eldest at present a lieutenant in the Royal Army Medical Corps, and the other a fleet-surgeon in the Royal Navy.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Report of the Mesopotamia Commission.

THE report of the Commission to inquire into the Operations of the War in Mesopotamia was presented to Parliament on Tuesday last, and in many directions disclosed lamentable ignorance and laziness as well as ill-founded optimism on the part of the military and civil authorities who were responsible for the planning of the campaign. The breakdown in medical arrangements was not made the subject of a separate report, as had been expected, but forms the whole of a separate section of the general report. In this part of the report the Commission criticises the work of Surgeon-General BABTIE, who was Director of Medical Services in India up to June, 1915, although admitting that his experience in his post when the war broke out had been very short, and that he had to work in an atmosphere unfavourable to reform. But no excuse is made by the Commission for the action of Surgeon-General HATHAWAY, who, as Principal Medical Officer in Mesopotamia, officially reported "Wounded satisfactorily disposed of," and throughout the campaign suppressed the unpleasant. The Government will be pressed to give a day for a discussion of the report.

Military Service (Review of Exceptions) Act.

In the course of debate in the House of Commons on Thursday, June 21st, Mr. MACPHERSON, the Under Secretary for War, announced that the Government is willing to appoint a small Parliamentary Committee to examine into the working of the Military Service (Review of Exceptions) Act. The administration of the statute and the system of medical re-examinations which have taken place under it have given rise to considerable criticism in the House of Commons, and the subject was reviewed by speakers in all quarters. The discussion took place in Committee of Supply on Army Estimates.

Mr. PRINGLE introduced the subject by moving a reduction of £100 in the salary of the Secretary of State for War. His object, he said, was to call attention to what he thought might be described as the scandals in connexion with the medical re-examination of discharged and rejected men under the Military Service (Review of Exceptions) Act. When that Act was passed some months ago assurances were given that if the re-examination were carried out, it would be carried out with exceptional care and kindness. But the recruiting authorities had shown absolutely no discretion and discrimination in the way in which they had called men up. In nearly every area in the country they had sent out notices for re-examination not only to men who had obtained fraudulent exemption or had been carelessly examined or who, they had reason to believe, had improved in health, but they had called upon the halt, the lame, the blind, the mute, the mad, and even the dead to appear before the examining boards. When men were actually admitted to re-examination they were, as a rule, treated with the utmost harshness. If they presented any evidence at all regarding their medical condition—and they were entitled to do that for the guidance of the medical board, and, indeed, in the House of Commons they had been invited to do that—the certificates were systematically ignored and often torn up in their faces. The examination itself was often of the most perfunctory character. It was true that there were usually three medical officers present, but in the great majority of cases the decision rested with the military officer who was chairman of the board. Having dealt with certain individual cases the honourable Member said that there was complete evidence that many thousands of men were being taken into the Army to-day, and had been taken in during recent months, who were unfit for any form of service.

Sir GODFREY BARING said that as chairman of an appeal tribunal his confidence in medical boards had been rudely shaken. Many of the chairmen of district medical boards were members of the Royal Army Medical Corps. He did not wish to say anything against their honour or integrity, but it must be evident that men who were dependent on the War Office for their professional advancement must wish to do what they believed the War Office required. He believed that these men thought that what the War Office required was quantity, not quality. He should like to see a larger number of civilian medical men made chairmen of medical boards, men who were wholly independent of the War Office.

Reply for the War Office.

Mr. MACPHERSON (Under Secretary for War) in his reply insisted that the War Office was acting in good faith. It was hoped by the re-examinations under the Act to get 60,000 "A" men and 60,000 for the other categories, in all 120,000 men. But it had been expected that 920,000 or 950,000 might be called upon for medical examination, and thus these called up for re-examination would in very many cases not see service. Men were now required for the Army whose work could be very well performed by women. The Army to-day was quite a different organisation from the Army of three years ago. Labour in the Army, for instance, had become quite a different problem, and a gigantic problem. Men were required at the front now to look after and drive trains and lorries, to look after horses, to make roads, to check and issue stores, to sterilise clothes, to look after washhouses and baths, to repair harness, boots, and clothes, and to mend rifles. In fact, any man sufficiently well to earn a livelihood in his civil capacity could be of use in the Army. It required one-and-a-half men behind the lines to keep one man in the trenches. That fact was forgotten in many of the speeches that had been made. The representation was made that all men who were suffering from wounds or poisonous gas or neurasthenia were called up for service. But the

Statutory Order, which was sent to every man who might be liable for re-examination, stated that the notice did not apply to men discharged in consequence of disablement, if it had been certified under the authority of the Army Council or the Admiralty to be the result of wounds (including injury from poisonous gas) received in battle or in any engagement with the enemy or otherwise from the enemy, or in consequence of neurasthenia or allied functional nerve disease, if so certified by a special medical board to be the result of naval or military service in the present war. All that the man had to do was to fill in the form at the back and send it to the recruiting officer, and probably then he would hear no more about it. The only further thing he wished to mention was that he agreed that this re-examination experience might have inflicted hardship. The Government had recognised that, and it was now prepared to say that all men who had served abroad and had been discharged from the Army, and were now coming compulsorily under this Act, if they made a claim at once would be finally discharged. That was to say, every soldier who was disabled by wounds or discharged from sickness or ill-health abroad would be excepted under this Act.

Mr. HOGGE: Is that a concession?

Mr. MACPHERSON: Yes.

Mr. HOGGE: When?

Mr. MACPHERSON: I do not know when it will apply, but it will apply to all those mentioned by me. It had been stated frequently that the War Office issued secret instructions to medical officers, and that on the strength of these instructions men were being forced into the Army. He had denied in the House that any such secret instructions were issued. He denied it again, and he would ask his honourable friend (Mr. Hogge) if he could produce them.

Mr. HOGGE: I have seen them.

Mr. MACPHERSON: Will the honourable Member produce them?

Mr. HOGGE: If the position of the men is not prejudiced. Will you give a pledge of complete immunity?

Mr. MACPHERSON: Certainly. I asked the honourable Member if he would produce these instructions.

Mr. HOGGE: And I said I could do it.

Mr. MACPHERSON: If those instructions were issued—and they were not—they were issued to professional gentlemen. That was the allegation. He did not think any member of a high profession such as the medical profession would receive instructions from anybody without something in writing. Did honourable Members think that Sir Frederick Treves of the Central Medical Board or other men of high professional standing would receive instructions? They would tear up in righteous indignation any secret instructions that might be given by the War Office.

Army Council's Instruction.

As a matter of fact one instruction only was issued and it was contained in the Army Council orders. He gave a pledge that every consideration should be given to every man called up for re examination. The honourable gentleman then quoted at length this instruction. It stated that the Army Council directed that the greatest care and consideration in medical re-examination should be shown for disabled men. Many of them had served overseas, and of those who had so served only men who on re-examination were found fit for category A or for category B (1), B (2), or C (1) were to be called for service. The remainder, men although categorised C (2), B (3), or C (3), were to be allowed to return home. Disabled men who had not served overseas were in a slightly different position. They also deserved in the majority of cases consideration. There were, however, amongst them certain persistent malingerers, and also a certain number who in the earlier days of the war were improperly discharged on inadequate grounds. Even so it was essential that these men should be examined considerately. With regard to the posting of such discharged men as were taken for service and were lower than category A, the policy of the Army Council was that these men should be exposed to the least possible risk of further wounding or disease. In all cases it must be remembered that these men had already served, that many of them had faced trying experiences, and it was not to be expected that on the average their nerve would be as sound as it had been. This Army Council instruction was sent to all medical officers. Men were being examined at the rate of 15,000 a day, and there was a very much depleted staff of medical men to deal with these enormous numbers. If the medical board was in a rural district the president of the board asked the local medical men to assist him, and the board was invariably composed of no fewer than the president and two medical men, but the average board consisted of the president and four members, and at least three medical men passed each case through their hands. If it happened to be an important centre and not a rural area, the local medical board executive committee found the personnel of the board and formed a panel, and he understood that in that case, too, the medical board invariably consisted of the president and two members, and sometimes the president and four members.

Sir R. ADKINS: Can the president's decision override that of his two or four colleagues?

Mr. MACPHERSON: I cannot say definitely at the moment. He went on to point out that for men who had got leave to go before a special medical board, three such boards had been established. In addition, the War Office had recently appointed inspecting officers. The War Office had the advantage of having at headquarters the distinguished services of Colonel James Galloway, who was senior physician to Charing Cross Hospital, and there were the travelling inspectors under General Burney, six of whom had visited every medical board in the country. The inspectors were visiting the main recruiting areas and the areas from which complaints had come. It was quite easy to come to the floor of the House and to make out a case by citing individual cases and investigated cases, but upon the general policy of the War Office he made bold to say that wherever an instance of injustice was brought to its notice individually it had been investigated. In reference to what he had said as to the system of inspection by those medical boards which had been instituted, the inspectors were doing their level best to make the work of those boards as satisfactory and as fair as possible to the unfortunate men who in this great national crisis had to be called upon again to be examined in case they might be of some further service. The Government, he was authorised to say, was quite willing and quite ready to appoint a small Parliamentary Committee to do what the Government had already done—to examine into the working of this Act. The War Office was prepared to meet any criticism or any attack that might be made.

Mr. Asquith's Criticisms.

Mr. ASQUITH said that the decision to appoint a Parliamentary Committee had relieved him of a considerable burden. No one could have listened to the two speeches with which this discussion was introduced, and no Member of the House could recall the contents of his letter-bag during the course of the last six weeks without feeling whether or not the 120,000 men had been obtained that they had been got by means which had excited widespread displeasure and indignation. He was not making any charge against the authorities or the War Office, and he was glad that the circular which the Army Council issued was going to be made public. It seemed to him to have been well conceived and well expressed. Instructions, and, indeed, the best paper safeguards which could be invented, would not, in circumstances such as these, prevent the occurrence of gross local and personal cases of hardship. The right honourable gentleman went on to say that he had letters which came to him from every part of the country which convinced him, looking at this thing quite impartially, that everywhere there were men whom no reasonable body of medical or other experts ought ever to have dreamt of passing, he would not say for general service but for any form of military service whatsoever. They frequently complained—he was afraid because these medical boards were very congested with the business—that they, after what had been a very brief and perfunctory examination, and in defiance of the opinion of the medical practitioners who knew the history of the individual concerned, had been passed in an almost reckless fashion into one or other of these categories. He was sorry to say that the evidence on that point was absolutely overwhelming. There was no honourable Member in any quarter of the House hardly who had not received evidence of that fact and that the right of appeal available was very insufficient protection. The right honourable gentleman then dealt with the 490 appeals to the County of London Tribunal in the course of nine months. Of these appeals, in 28½ per cent. of the cases there was no alteration; in little more than 10 per cent. the category in which the man was placed was raised, and in 60 per cent. the category was lowered, and in nearly 20 per cent. of that 60 per cent. not only was the category lowered but the man was referred back or rejected altogether. That showed that in this tribunal in considerably more than half the cases the opinion of the medical board was reversed. If that had been the case in the County of London, honourable members might be sure that it had been the case in other parts of the country also. He did not want in any way to forestall the conclusions of the committee which he was glad was going to be appointed, but he would venture to make one or two suggestions. He thought that the constitution of the medical tribunals of first instance ought to be modified and improved. If it was a fact, as had been stated, that the president had the power—he did not know whether it was so or not—

Mr. BONAR LAW (the Chancellor of the Exchequer): It is not so.

Mr. ASQUITH: My right honourable friend says it is not so, and I am sure it is not intended to be within the competence of the president to overrule the opinion of his colleagues. But has it been the practice that the president of these tribunals had overriden the opinions of his colleagues? If it had, that seemed to indicate a line of reform which he would suggest first and foremost, that it should be clearly understood that there was complete parity of authority between the different members of the medical board, and next, that as far as possible the president of the board should be a person who was not himself in the employment of the War Office. Another suggestion which he should like to make was in regard to men who had been at the front, men who had been wounded and invalided, that when they had been recalled and it had been decided that they were not fit to return the decision should be taken as final.

Mr. BONAR LAW: I think that is the case now.

Mr. ASQUITH: Not from the information which reaches me. What he had said had not been animated by any unduly critical spirit.

Honest Attempt to Administer the Act.

Mr. BONAR LAW said that he asked the House to believe that there had been an honest attempt on the part of the War Office to carry out what was the deliberate intention of the Government and the House when the Act was passed. The right honourable gentleman had made a suggestion about the composition of medical boards. It was quite obvious that the appeals could only in any case be a very limited number. He wanted the House to understand what the Government did in this matter. Before the Bill was passed they knew that there would be the need for a far larger force of medical examiners than before. They took all the steps in their power to get competent men. In December last year Colonel Galloway, who was a leading physician at Charing Cross Hospital and an examiner in London University, was appointed by the Government as inspector of these medical boards. He had seen him, and Colonel Galloway had told him that he himself had examined and visited almost every one of them. The House would not think it out of place if he read Colonel Galloway's account of these boards. This was what he said: "There must be errors made from time to time among the large number of decisions arrived at by these medical boards. There must be cases in which differences of temperament of the men under examination and of the medical examiners give rise to friction and cause for complaint. But on occasions too numerous to mention I have been a witness to the patience and courtesy shown by members of the medical boards in cases where these qualities have been subjected to severe trial." Colonel Galloway went on to say that in his opinion these medical boards, the members of which were almost entirely civilian though holding temporary Army commissions and who had their private practices to fall back upon, were rendering great service to the country, and that one of the results of this kind of criticism was that they had the feeling that neither the Government nor the House of Commons was supporting them in their work, and that they were not getting credit for the great services which they were rendering to the country. He (Mr. Bonar Law) was not disposed in the smallest degree to come here on behalf of the Government in a spirit of apology. He was satisfied that at no time had any of the work of the War Office been done so conscientiously, and he doubted whether it had been done more effectively

In the course of the subsequent discussion Mr. NIELD expressed the view that the whole subject of medical re-examinations needed to be inquired into and drastically overhauled. Sir W. COLLINS emphasised the desirability of giving greater opportunities of access to the special

medical boards. Sir R. ADKINS criticised the medical re-examinations. Mr. HOGGE urged that the Committee of Inquiry should be speedily set to work.

The motion for the reduction of the vote was ultimately withdrawn by Mr. Pringle on the ground that a committee was to be appointed.

Committee Appointed.

On Tuesday, June 26th, a Select Committee of the House of Commons was appointed to inquire into and report upon the instructions issued by the War Office with regard to the administration of the Military Service (Review of Exceptions) Act and on the method, conduct, and general administration of medical examinations under the Military Service Acts. The Committee consists of Sir G. BARING, Mr. MONTAGUE BARLOW, Mr. COCHRANE, Colonel FABER, Colonel GRETTON, Mr. H. LAW, Mr. NIELD, Mr. PRINGLE, Mr. CARADOC REES, Mr. SHORTT, and Mr. SUTTON.

HOUSE OF COMMONS.

THURSDAY, JUNE 21ST.

Casualties amongst Medical Officers.

Mr. MACCALLUM SCOTT asked the Under Secretary for War how many medical officers had been killed and wounded respectively since the commencement of the war.—Mr. MACPHERSON answered: The numbers of Regular (including temporary commissioned) and Territorial officers have been as follows:—

Killed in action	137
Died of wounds	58
Died of disease	62
Wounded	707
Total	964

Figures for Colonial officers are not readily available.

Medical Students in England and Scotland.

Mr. MACCALLUM SCOTT asked the Parliamentary Secretary to the Board of Education what were the most recent figures of the number of medical students, men and women respectively, in England and Wales, as compared with the number in the year before the war.—Mr. LEWIS replied: The numbers of medical students in medical schools receiving grants from the Board of Education in 1913-14 and 1916-17 are 3483 and 1981 respectively. The returns made to the Board do not distinguish between men and women students. The figures do not include the medical schools at Oxford University, Guy's and Middlesex Hospitals, Bristol University, or the University Colleges of Nottingham, Reading, Southampton, and Cardiff, with regard to which the Board is unable to supply similar information.

Replying to Mr. MACCALLUM SCOTT, Mr. MUNRO (Secretary for Scotland) stated that he was informed that the figures of medical students attending Scottish Universities were approximately as follows: In the year before the war, 2367 men and 236 women; in the present year, 1510 men and 696 women.

Superannuation of Officers under the Mental Deficiency Act.

Replying to Mr. YEO, Mr. BRACE (Under Secretary at the Home Department) said that an order would be issued in due course applying the provisions of the Asylum Officers' Superannuation Act to the officers of certified institutions provided by local authorities under the Mental Deficiency Act. Some difficulties had, however, arisen. In particular, there was no power as the Acts stood at present to aggregate service in these institutions with service in asylums. These difficulties could only be removed by fresh legislation. The matter was not being lost sight of, but it would be impossible, he was afraid, to take it up this session.

Acting Promotion of R.A.M.C. Officers.

Captain WRIGHT asked the Under Secretary for War why appropriate acting rank was given to officers of the Royal Army Medical Corps recently sent overseas with special Territorial general hospitals, who were by special arrangement to serve for a minimum period of three months and to be relieved when necessary, when similar appropriate acting rank had been refused to officers of the same corps occupying similar positions in Territorial hospitals in France who had been serving in His Majesty's forces before the war and continuously since mobilisation, and in some cases for over two years at the front, and who were subject to no such special arrangements as to minimum period of service or relief.—Mr. MACPHERSON wrote, in reply: When a general hospital is mobilised at home appropriate rank is given to the superior officers of the unit, but it has been decided that acting promotions need not be given in the case of vacancies occurring in units serving abroad. As stated in my reply last week, the question of acting promotions in such cases is under consideration.

MONDAY, JUNE 25TH.

Protection of Troops from Venereal Disease.

Sir G. GREENWOOD asked the Chancellor of the Exchequer whether the Home Office and the War Office had now come to an agreement as to the administrative action to be taken in order to protect the oversea troops from venereal disease; and whether he could state what form such action would take.—Mr. BONAR LAW replied: The military and police authorities are already using such powers as they possess to deal with the evil referred to in the question, and it appears doubtful whether more can be done without legislation, but the matter is receiving constant consideration.

TUESDAY, JUNE 26TH.

Lunatic Soldiers.

In answer to Sir G. TOULMIN, Mr. BARNES (Minister of Pensions) said: The cost of maintenance of a discharged soldier under detention in an asylum is chargeable against his pension under the Lunacy Act, 1890, and the Royal Warrant of December, 1914. I have now arranged that a discharged disabled man shall, while in an asylum, be treated on the footing of a private patient, his maintenance being paid for by the State. An extra payment of 3*s.* 9*d.* a week is made to the asylum authorities to enable them to provide suitable private clothing and other amenities for the man, and 2*s.* 6*d.* is given to the man himself for personal comforts. Under Article 6 of the New Warrant and Order in Council special provision is made for the maintenance of the family and dependants of a man in an asylum whose disability is due to war service. The right honourable gentleman also said (in answer to Mr. ELLIS GRIFFITH): If the lunacy is attributable to, or aggravated by, service, the man's wife will, from the date following the man's discharge from the service, receive the same allowance as would be granted to her if she had been left a widow, together with allowances for any children. His dependants will be similarly provided for. If the lunacy is not so attributable or aggravated, the gratuity, in most cases a substantial one, which would have been awarded to the man will be administered by the Ministry in the interests of the man's family under the Lunacy Act of 1890.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

BREW, E. V., has been appointed Medical Officer of Health for the Clutton (Somerset) Rural District.

ELDER, W., M.B., Ch.B. Glasg., Certifying Surgeon under the Factory and Workshop Acts for the Annan District of the County of Dumfries.

HARCOURT, M. A., M.B., Ch.B. Edin., Temporary Medical Officer and School Medical Officer for the County of Holland (Lincolnshire).

RICHMOND, JAMES ROBERT MARR, L.S.A., L.M.S.S.A. Lond., Acting Medical Officer of Health for the St. Just (Cornwall) Urban District.

STAPLE, JAMES D., M.R.C.S. Eng., Temporary Honorary Medical Officer to the Lyme Regis Cottage Hospital.

WHITWORTH, WILLIAM CUTHBERT, L.R.C.P., M.R.C.S., Temporary Medical Officer for the St. Agnes and Perran Districts by the Truro (Cornwall) Board of Guardians.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).
When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

ABERDEEN ROYAL ASYLUM.—Temporary Assistant Physician. Salary from £250 to £350 per annum, with board, &c.

BELGRAVE HOSPITAL FOR CHILDREN, Clapham-road, S.W.—Resident Medical Officer for six months. Salary at rate of £75 per annum, with board, &c.

BIRMINGHAM.—Female Locum Tenens for Infant Consultation Work for three months. Salary 8 guineas per week.

BOURNEMOUTH, ROYAL VICTORIA AND WEST HANTS HOSPITAL, Boscombe Branch.—Resident Medical Officer. Salary £300 per annum, with board, &c.

BRISTOL ROYAL INFIRMARY.—House Physician and House Surgeon. Salary at rate of £120 per annum, with board, &c.

BURTON-ON-TRENT INFIRMARY.—Resident House Surgeon. Salary £250 per annum, with board, &c.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Resident House Physician. Salary £250 per annum, with board, &c.

DARLINGTON GENERAL HOSPITAL.—House Surgeon. Salary £200 per annum, with board, &c.

DEVONPORT, ROYAL ALBERT HOSPITAL.—House Surgeon, unmarried. Salary £150 per annum, with board, &c.

FARNWORTH, BOLTON, TOWNLEYS MILITARY HOSPITAL.—Female Assistant Medical Officer. Salary £383 5*s.* per annum, with rations, &c.

FOLKESTONE, ROYAL VICTORIA HOSPITAL.—Resident Medical Officer. Salary £200 per annum, with board, &c.

GLOUCESTERSHIRE ROYAL INFIRMARY AND EYE INSTITUTION.—Assistant House Surgeon. Salary £150 per annum, with board, &c.

HAMPSTEAD GENERAL HOSPITAL, Haverstock Hill.—Resident House Physician for six months. Salary at rate of £200 per annum.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—House Physician for six months. Salary 30 guineas.

LEICESTERSHIRE EDUCATION COMMITTEE.—Temporary Assistant School Medical Officers. Salary at rate of £360 per annum.

MANCHESTER CHILDREN'S HOSPITAL, Pendlebury, near Manchester.—Two Female Resident Medical Officers, unmarried. Salary at rate of £200 per annum.

MANCHESTER UNION, NELL LANE MILITARY HOSPITAL, West Didsbury.—Locum Assistant Resident Medical Officer. Salary £7 7s. per week, with board, &c.

MELTON, SUFFOLK, ST. AUDRY'S HOSPITAL FOR MENTAL DISEASES FOR THE COUNTY OF SUFFOLK.—Second Assistant Medical Officer. Salary £250 per annum, with board, &c.; if married, £350 per annum, with board for self only.

NOTTINGHAM GENERAL HOSPITAL.—Holiday Locum Tenens, Female. Salary at rate of £250 per annum, with board, &c.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—House Physician. Salary £200 per annum, with board, &c.

PORTSMOUTH PARISH WORKHOUSE INFIRMARY, WORKHOUSE, AND CHILDREN'S HOME.—First Assistant Medical Officer. Salary £250 per annum, with rations, &c.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Assistant Resident Medical Officer for four months. Salary at rate of £60 per annum, with board, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Examiner in Dental Surgery. Also Election to the Court of Examiners.

ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C.—Third House Surgeon. Salary at rate of £50 per annum, with board, &c.

SALFORD UNION INFIRMARY, Hope, Pendleton, near Manchester.—Female Assistant Resident Medical Officer. Salary £250 per annum, with rations, &c.

SHEFFIELD ROYAL INFIRMARY.—House Physician. Salary £120 per annum, with board, &c.

SOUTH LONDON HOSPITAL FOR WOMEN, South Side, Clapham Common, S.W.—Female House Physician and House Surgeon for six months. Salary at rate of £100 per annum each, with board, &c.

STOKE-ON-TRENT COUNTY BOROUGH.—Female Assistant Medical Officer, in connexion with Maternity and Child Welfare Work, &c. Salary £350 per annum.

SUNDERLAND COUNTY BOROUGH.—Temporary Tuberculosis Medical Officer. Salary at rate of £500 per annum.

WOKINGHAM, BERKS, PINEWOOD SANATORIUM FOR TUBERCULOSIS.—Medical Superintendent. Salary £500 per annum, with board, &c.

WOLVERHAMPTON AND MIDLAND COUNTIES EYE INFIRMARY.—House Surgeon. Salary £150 per annum, with board, &c.

YORK, CITY OF.—Temporary Tuberculosis Officer. Salary at rate of £500 per annum.

Births, Marriages, and Deaths.

BIRTHS.

BRENAN.—On June 19th, at Carlton-road, Sidcup, the wife of Captain A. R. M. Brenan, R.A.M.C., of a son.

FALWASSER.—On June 23rd, at Warwick House, Maidstone, the wife of Lieutenant-Colonel A. T. Falwasser, R.A.M.C.T., of a daughter.

HAMILTON.—On June 17th, at Holmesdale-road, Sevenoaks, and of Lifford House, Dartford, the wife of Major Hamilton, R.A.M.C.T., of a daughter.

KILLICK.—On June 21st, at Trinity House, Maidstone, the wife of Captain C. Killick, R.A.M.C., of a son.

PALMER.—On June 20th, at Nottingham-place, W., the wife of Captain A. C. Palmer, R.A.M.C., F.R.C.S., of a son.

WOOLLARD.—On June 22nd, at Osnaburgh-terrace, N.W., the wife of Herbert Henry Woollard, M.D., Major, A.A.M.C., of a son.

MARRIAGES.

BATE–TROUBRIDGE.—On June 21st, at Christ Church, Chelsea, John Brabant Bate, Captain, R.A.M.C.T., and West African Medical Staff, to Helen Cecil Margaret, youngest daughter of the late Colonel Sir Thomas Troubridge, Bart., C.B.

ELLIS—FRASER.—On June 18th, at St. Mary Abbots Church, Kensington, Captain G. W. Ellis, R.A.M.C.(T.), to Mary Taylor, only daughter of Mr. John Fraser.

MONTGOMERY–MCELROY.—On June 20th, at St. Charles's, Ogle-street, W., by the Rev. Ernest D. Hanifin, Samuel Alexander Montgomery, Captain, R.A.M.C., to Nellie Teresa, daughter of the late Mr. Bernard McElroy, Leigherntain, Killala, co. Mayo.

RUDKIN—WINCH.—On June 23rd, at Holy Trinity Church, Northwood, Captain G. W. R. Rudkin, R.A.M.C., to Alice Edith, eldest daughter of R. F. Winch, M.A. Cantab., and Mrs. Winch, of St. Valery, Northwood.

DEATHS.

BALLANTYNE.—On June 26th, at Holker House, Darwen, James Todd Ballantyne, Physician and Surgeon, the much-loved husband of Susannah Ballantyne, in his 73rd year. Funeral, Saturday, June 30th. Service, Belgrave Chapel, Darwen, 10.30 A.M.

BELL.—On June 19th, at Rathwell, Manitoba, Canada, Robert Bell, M.D., LL.D., D.Sc. Camb., F.R.S., and late of the Geological Survey of Canada, Ottawa.

MILWARD.—On June 18th, at Stanton-road, Wimbledon, James Milward, M.D., M.R.C.S. Eng., L.S.A.

SHELDON.—On June 20th, at Powis-square, W., Thomas Sheldon, M.D., J.P., aged 82.

WRIGHTSON.—On June 20th, at Clare House, Aldeburgh, Suffolk, Richard Blayney Wrightson, M.D.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

ANTHRAX SPREAD BY SHAVING BRUSHES.

IN the later months of 1915, and again at intervals in the course of the succeeding year, outbreaks of anthrax occurred in this country which were suspected to be due to infection conveyed by shaving brushes. In THE LANCET of Jan. 1st, 1916, we published a paper by Dr. Reginald R. Elworthy, who had treated several cases at the West London Hospital. These were the first cases hitherto recorded in which malignant pustule or external anthrax had been caused by this means, and subsequent inquiry revealed the fact that other shaving brushes had been discovered which were grossly contaminated with these bacilli. Dr. Elworthy's investigations proved that infection in the first case was due to the use of a recently purchased shaving brush. The presence of virulent anthrax spores was demonstrated in this brush, and also in several unused brushes of similar pattern, purchased at the shop which supplied the original brush. Another case of anthrax occurring about the same time, which was traceable to the same cause, a further investigation was made which established the common origin of all the cases in a single factory. The matter coming to the notice of the Local Government Board a further investigation of the facts has been made by Dr. Francis J. H. Coutts, whose report[1] has recently been issued by the Board's principal medical officer. In addition to the above cases, in which brushes manufactured in England were implicated, there were, it appears, four further cases of anthrax traceable to brushes of foreign manufacture, two of which occurred in soldiers. The brushes in this case had been made either in Canada, America, or Japan. The full details of Dr. Coutts's report show that, although the danger of anthrax from infected shaving brushes may be limited in extent, it nevertheless constitutes an appreciable risk which ought to be removed. The Board are considering what administrative action, by way of guarantee or otherwise, is required to secure that all brushes used for this purpose shall be free from infection.

THE MESSAGE OF THE ARTISTS.

MANY of the leading British artists have combined to show in a series of lithographic prints the aims of Britain and her Allies in the war, and also some typical and impressive aspects of the British effort against the enemy. The British aims are shown in a series of allegories printed in colour. "The Freedom of the Seas" is rendered by Mr. Frank Brangwyn, "The Restoration of Belgium" by Mr. George Clausen. Other subjects are undertaken by Mr. Dulac, Mr. M. Greiffenhagen, Mr. Augustus John, Mr. Ernest Jackson, Mr. Gerald Moira, Mr. William Nicholson, Mr. Charles Ricketts, Mr. W. Rothenstein, Mr. Charles Shannon, and Mr. Edmund J. Sullivan. The British effort is typified in several series, such as "Making Soldiers," by Mr. Eric Kennington; "Making Ships," by Mr. Muirhead Bone; and other series by Mr. Frank Brangwyn, Mr. Clausen, Mr. Nevinson, Mr. Hartrick, Mr. Charles Pears, Mr. W. Rothenstein, and Mr. Claude Shepperson. The works will be exhibited in the first instance in the Galleries of the Fine Art Society, New Bond-street, London, for a period dating from July 6th, and afterwards in galleries throughout the country. Arrangements will also be made for their display in Allied and neutral countries.

A SURVIVAL OF ARCHAIC THERAPEUTICS.

To the Editor of THE LANCET.

SIR,—One is not easily surprised nowadays, but I have been surprised recently by a survival of archaic therapeutics which has come to my notice. The patient was a coachman in a good position. Lately he had been acting as gardener and, when using a heavy curved hedger's knife, inflicted a sharp cut on the left wrist at the base of the thumb, baring, but not dividing, two of the extensor tendons. He came to me about eight hours afterwards. On removing a dry dressing a wound about 1½ inches long cleanly united was revealed, evidently closed by "primary union." There was a peculiar yellowish powdery efflorescence about its edges, and I asked what he had applied. "Oh, a very old-fashioned remedy. I just made water over it once or twice while it was still open." Questioned further, he said that this recipe for using fresh urine had been in his family for many years and had come originally from an old "soldier man" of great experience.

[1] Reports on Public Health and Medical Subjects, No. 112, pp. 20, price 6d.

Asked if many still used the method he said, "Oh, there's a goodish few does—them as knows it." It was for fresh wounds only that he recommended urine, not to be applied as a dressing, but solely by natural irrigation. He does not approve of its use as a collyrium for the eyes; and I remember years ago a disgusting old man in the workhouse, bleary with chronic conjunctivitis, whose long-suffering fellows at last complained of his society by reason of his offensive odour. He was ammoniacal—very, and as he apparently contrived to saturate his clothing upwards, right up to the chin, he was followed in one of his frequent visits to the lavatory, and there was seen laboriously to douche both eyes, using the cupped palm of either hand alternately as an eye-bath, after which he returned to the sitting-room. Here the result was not good; in fact, changing the prescription at once produced improvement; but in the case of the cut wrist I am bound to say that I have never seen a fairly severe cut unite more satisfactorily; there was complete absence of inflammation and the union was permanent.

I am, Sir, yours faithfully,

Bromsgrove, June 15th, 1917. H. CAMERON KIDD.

PS.—Since the above was written the patient further informs me that his prescription is well known as an infallible remedy in veterinary work for recent wounds in horses.

CHEESE-MAKING IN CORNWALL.

THE Cornwall County Cheese School has had a successful four weeks' course of demonstration at Egloskerry. The chairman, at the close of the session, said that cheese-making could be made profitable, as from 393 gallons of milk the students had made 393 lb. of cheese.

MOHAIR AND ANTHRAX.

THE Director of Army Contracts is now undertaking a census of stocks of wool and wool products and of fabrics containing wool suitable for clothing. There is a medical side in this, and especially is mohair a subject of medical interest. The scarcity of mohair makes itself known to the ordinary man nowadays when he demands a pair of mohair boot-laces, but the medical man thinks of mohair chiefly from its connexion with the history of anthrax, first noted in the Bradford district after the introduction of alpaca and mohair as textile materials in 1837. The amount then used was small, but 30 years later, in 1867, the amount of mohair imported into the United Kingdom from Turkey was 2,421,188 lb., valued at £312,986, and from British South Africa only 43,348 lb., valued at £4985. Thirty years later, in 1897, we imported from Turkey 10,701,390 lb., valued at £742,203, and an enormously increased amount from South Africa of 12,055,390 lb., valued at £634,419. Just before the war, although the amount imported from Turkey was about the same as in 1897, the import from British South Africa had risen to over 24,000,000 lb., valued at over a million sterling. The number of Angora goats in South Africa, ascertained at the census taken in 1911, was 4,275,335, over 3,000,000 of them being in Cape Province. The possession of this number of goats explains the large increase in production of mohair. In 1867 the average price of mohair was 31*d.* per lb.; in 1897, 14½*d.* per lb.; and just before the war had descended to 11*d.* per lb., although the Turkish was 14*d.* per lb. Bradford is the centre of the mohair-spinning trade of the world, so that its influence over the spread of anthrax is mainly felt in this country. Where cases of anthrax have been traced to mohair it is to the Turkish product in the majority of instances. The average production of mohair per annum from each Angora goat is about 2½ lb. In South Africa there is a summer and winter clip, giving long and short hair. The South Africans have taken immense trouble and expense in introducing high-class rams and ewes from Persia, Cashmere, and different parts of Europe, but notwithstanding the quality of the mohair varies in different localities. Bradford, actively concerned in preventing anthrax in its workers and products, has instituted many inquiries into the pathology and spread of the disease. Several sera have been invented for the treatment of the disease, the latest of which was referred to in THE LANCET of May 12th, 1917. Much progress has been made in therapeutics recently, but further study is sure to be repaid. But the war having reduced the supply of mohair from Turkey must have had an influence on the cases of anthrax as well as on textile trade and the personal requirements of the public. The stoppage of imports of many of the articles to which we had become accustomed has undoubtedly often a medical side not always immediately perceivable, and there is a fortunate side to a scarcity of hides and hair.

The following journals, magazines, &c. have been received:—Archives of Pediatrics, Pediatrics, American Journal of Medical Sciences, American Journal of Roentgenology, American Journal of Surgery, Bulletin of the Johns Hopkins Hospital, American Journal of Public Health, Anales de la Facultad de Medicina de Granada, Medical Journal of South Africa, Indian Journal of Medical Research, Anales de la Facultad de Medicina, Montevideo, Cornhill Magazine, &c.

Medical Diary for the ensuing Week.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patients (Mr. H. Gillespie). 2.30 P.M., Medical Out-patients (Dr. T. R. Whipham): Gynæcological Out-patients (Dr. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

TUESDAY.—2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. Howell Evans); Nose, Throat, and Ear Out-patients (Mr. C. H. Hayton). Radiography (Dr. Metcalfe). 3.30 P.M., Medical In-patients (Dr. A. J. Whiting).

WEDNESDAY.—Clinics:—2.30 P.M., Throat Operations (Mr. C. H. Hayton). Children Out-patients (Dr. T. R. Whipham); Eye Out-patients (Mr. R. P. Brooks); Skin Out-patients (Dr. H. W. Barber). 5.30 P.M., Eye Operations (Mr. R. P. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patients (Dr. A. J. Whiting); Surgical Out-patients (Mr. Carson); Radiography (Dr. Metcalfe). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

FRIDAY.—2.30 P.M., Surgical Operations (Mr. Howell Evans). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. H. Gillespie); Eye Out-patients (Mr. R. P. Brooks).

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

ROYAL INSTITUTE OF PUBLIC HEALTH, Lecture Hall of the Institute, 37, Russell-square, W.C. 1.

Course of Lectures and Discussions on Public Health Problems under War and After-war Conditions:—

WEDNESDAY.—4 P.M., Lecture XII.:—Prof. E. W. Hope: Civil Sanitation and the War. Followed by a discussion.

BOOKS, ETC., RECEIVED.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.*

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C. 2.

MANAGER'S NOTICES.

ALTERATION IN THE PRICE OF "THE LANCET."

INCREASED war expenses and cost of production necessitate an increase of the price of THE LANCET. Commencing with the new year, the price was raised to 8*d*. The rates of subscription remain as revised in October.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C. 2, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION is published in time to catch the weekly Friday mails to all parts of the world.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given on page 3.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied.

NEWSPAPERS FOR NEUTRAL COUNTRIES.

Newspapers are not at present being sent forward to neutral European countries unless posted direct from the office of publishers or newsagents who have obtained permission from the War Office for this purpose. The Publisher of THE LANCET has obtained the required permission, and he will forward copies direct from the Office to any neutral country on receipt of instructions.

METEOROLOGICAL READINGS.

(*Taken daily at 8.30 a.m. by Steward's Instruments.*)
